Noble Water Lilies.—It is astonishing the beauty of these, in spite of the unfavourable weather this season. As we now have them they surpass in colour and form any flowers gathered in the hot-house. Escarboucle is splendid, and also Mrs. Richmond and Colosse. One of the most distinct of all is James Brydon. These are from Messrs. Wallace, of Colchester, who grow them well.

Gentiana lagodechiana.—This pretty and distinct species from the Caucasus is not the least worthy member of a race quite unique among blue-flowered alpine.

Forming a spreading prostrate tuft, the rich blue flowers, as large as those of a small *G. acaulis*, appear in clusters at the end of 9-inch long growths, the density of the trailing shoots preserving them well. The corolla lobes, widely parted and much reflexed, are connected at their bases by fringed divisions which give quite a distinct character to the flower, which is also marked by copious oblong, green spots. It is a good August-flowering kind.—E. H. J.

Water Lilies in Scotland.—The newer Water Lilies, which have done so much to adorn our ponds and lakes, are appreciated at Knockbren, Kirkcudbright, where Mr. James Brown has a good variety in the lake and in a little moat near the mansion. The best of the modern varieties of the *Marliacea* section and others are grown. This summer, since the warm weather has set in, these Water Lilies have been very fine.—S. A.

Fruit crops in the south of Ireland.—It is always interesting to compare notes, and I gathered from a friend who paid me a visit the other day that fruit appears to be quite a fortnight earlier in the south of Ireland than in the south-west of Scotland, Gooseberries, Currants, and Raspberries being finished before he left Waterford, while we were, at the time, in the midst of picking.—W. McGUFFOG, *Balmac, Kirkcudbright.*

Diplacus glutinosus in the open.—I had never previously looked upon *D. glutinosus* as being adapted for growing outside until the other day, when a gardener friend from the Waterford district of Ireland paid a visit to these gardens. Noticing some pieces of this plant in pots in a greenhouse he asked me if I ever tried it out of doors in this district, remarking that it succeeded perfectly, and, in a general way, proved quite hardy in the south of Ireland. I have no doubt that the plant would succeed here as well, for the climate is comparatively mild in winter; and I pass on the hint to those who may be interested in districts such as this.—Kirk.

The Californian Fuchsia (*Zauschneria californica*).—The spell of hot, dry weather which we have been having lately has suited this admirably, and it is now (beginning of August) in full blossom on a sunny retaining wall, its handsome, scarlet, tubular flowers supplying a welcome splash of bright colour at a time when there is not much in bloom on the wall. It grows very vigorously with me in a soil which has plenty of lime and

brick rubble mixed with it, and I fancy the dry conditions in which it is grown bring it into flower earlier, as I find many people complain of its being so late in coming into blossom that it is unable to do itself justice. Where it flowers freely and early it is an indispensable plant for the autumn rock garden.—NORTH LONDON.

Phlox Coquelicot.—Undoubtedly this is one of the best brightly-coloured kinds. When at Hampton Court at the close of July there were large groups of it in full bloom. Evidently it enjoys the cool soil by the way it grew. For years I have found this most useful grown from cuttings put into a close frame at any time in April. I put five or six cuttings into a pot, and when well rooted they are potted into 6-inch pots, grown on in the open, and planted out next year.—J. CROOK.

Rose Cardenia in the rock garden.—In the rock garden at Knockbren a prominent feature is a large plant of *Wichuraiana* Rose Gardenia, covering an artificial cliff with a veil of greenery and flowers. The value of these *Wichuraiana* Roses for covering sides of old quarries or steep rocky or other banks in the larger rock gardens has not yet been fully realised, but a look at Gardenia as grown at Knockbren should be sufficient to enable anyone to appreciate it. The long trails of glossy foliage and the hundreds of beautiful blooms make this Rose of high value for such a position. Although not a new Rose by any means, Gardenia is not easily surpassed. The blooms are yellow when opening, changing with age to very pale primrose.—S. A.

Dianthus Knappi.—If the dwarfier alpine species of the race—*alpinus*, neglected, and their like—obtain greater hold on the esteem of those who prefer the best of everything in plant life and beauty, room should be found for this distinct Hungarian species, which, rising to 1 foot or 15 inches high, produces its sulphur-yellow flowers in clustered heads after the manner of *atro-rubens* and others. While distinct in colour it offers a good opportunity to the hybridist to give us a new—probably intermediate—race of these plants, which might also link up the earliest flowering species with those of a later date. It is one of the flowers of the moment, and which gives of its blossoms to near the end of the month. Flowering profusely as is its wont, and becoming more or less exhausted as a result, it is best, despite its technically perennial

character, to raise it periodically from seeds in order to maintain an annual display. In other respects it offers no difficulty, succeeding well in loamy soils to which grit or old mortar has been freely added.—E. H. J.

Pernettyas.—I have always looked upon the berries as being the chief ornaments of these shrubs, and was surprised to find how handsome they can be when in blossom. Some fine specimens in the public gardens at Bournemouth, covered with the pretty white flowers, were very beautiful. *Pernettyas* must have peat to do their best, and if the soil has a tendency to moistness so much the better. They can be layered very readily; in fact, the branches which lie on the ground very soon put out roots without any assistance.—N. L.

Crocus Imperati.—As it is a good deal grown in this country it should not be difficult to obtain corms of *Crocus Imperati*, even if imported ones from Italy, its native country, are not forthcoming. In any case it is an inexpensive *Crocus*, which should be planted in some quantity for early bloom. It flowers from February to March, sometimes even coming in January. The fragrant blooms are of a pleasing lilac-purple, the exterior in most cases lined with deep purple. There are, however, self-coloured forms. The one called *C. l. longiflorus* is good, but the white varieties are rare and expensive. Corms should be ordered as soon as possible and planted about 2 inches deep in light soil in a sunny, sheltered position.—S. ARNOTT.

Gentiana Freyniana.—This is one of the most beautiful of the August-flowering species and one deserving well at the hands of all rock gardeners and lovers of alpine plants. From Asia Minor, the species has for companions at flowering time the Caucasian *G. septemfida* and its variety *G. s. latifolia* among others. Superior to the typical kind, it is equal, if not superior, to the variety named when richness of colouring and flower effect are taken into consideration, hence may be regarded as among the best, and, as such, good enough for all. Less erect, perhaps, than *G. septemfida latifolia*, it has leafy, foot-long, decumbent stems terminated by a cluster of large rich blue flowers that are paler internally and capable of fine effect when freely grouped. It does well in a deep, well-prepared bed of rich loam, leaf-mould, and sand. It is impatient of disturbance and root division, and easily raised from good, fresh seeds. By potting the seedlings singly, planting them out as soon as established in permanent positions a foot or so apart, the species is by no means difficult, while ranking with the indispensable at this season.—E. H. JENKINS.

Rose Gruss an Teplitz.—For colour, scent, and free growth this is to be recommended. I have noticed on strong soils it was shy blooming, especially if the knife is used too freely. In the light soil of West Surrey it may often be seen a mass of bloom for a long time. During July I saw a fine group of it in the gardens at Hawley Hill. Here many of the shoots had been left 4 feet long at pruning time. In a garden at Camberley the owner had used it in a big bed on a portion of the undressed grounds. In this instance the pruning was not severe, the object being to get a large mass of colour. In the centre of the bed many shoots had been left 6 feet or 8 feet, and when I saw it (about mid-July) nothing could be finer, the scent filling the air. The gardener at Hawley Hill told me nothing was more appreciated than big sprays of this cut 3 feet or 4 feet long and taken into the house. Another merit it has is that it

continues in bloom till late in the autumn. From its free growth it can be recommended for soils where many kinds would not do. Where space is limited then it may be grown on a pole or iron upright 8 feet or 10 feet high, treating it liberally at pruning time. This does well on its own roots.—J. C. F. C.

Hardy White Jasmines.—"K. R. W.," at page 382, writes interestingly of these, giving pride of place, or at least choice, to the typical white kind, *J. officinale*. I am prepared to go all the way with your correspondent in his admiration for the unequalled fragrance of this old garden favourite, but having conceded so much should thereafter give preference to the variety affine, because of its combining with fine fragrance a much more effective flower display and a decidedly less inclination to roam. Within a few yards of where this note is penned the variety affine has been giving hundreds of its clusters of white reddish-tubed flowers, the fragrance of which in the open, or gathered, is very pronounced, if somewhat less pleasing than in the type. In Sussex, on garden walls of less than 8 feet high, too, one recalls particularly good masses of its flowers from carefully trained specimens compressed into a space unsuited to *Jasminum officinale*, were its good flowering a matter for consideration. Where fuller scope is at hand the older kind may well find a place, and receiving due attention would give a better account of itself than it often does. Neglect is its frequent enemy, the density of a semi-wild state being responsible often enough for a rather sparse flowering.—E. H. J.

VEGETABLES.

SOWING SEEDS IN DRY WEATHER.

At the time of writing there is not the least sign of rain, and the surface soil is quite devoid of any semblance of moisture. Various rules are followed by gardeners who, from force of circumstances, have to sow for autumn and winter supplies, and this would apply with particular emphasis to Cabbages for spring cutting. One cannot afford to wait for the breaking up of the drought, or the possibility of a passing thunderstorm as an aid to the forwarding of Cabbage seeds, so the sower must devise some way of getting over the difficulty. The small grower might raise sufficient plants in a fair-sized seed-box, planting out as soon as opportunity offers. A spare light may do good service, as this can be shaded during the day and the light removed at night for the soil to benefit by the night dews. Some sow their seeds broadcast, and, after watering them, cover with mats or tar-dressed frame-covers. If fairly deep drills are drawn it is possible, with a fine-rosed pot, to water the lines each evening or early morning, the evening naturally being the better of the two. This course regularly followed will result in a fairly ready germination. Cabbages have been mentioned, and no one can gainsay the fact that this vegetable is one of the most important at the present time, though Carrots, Onions, Lettuces, Spinach, and Turnips are others that demand thought. The tropical nature of the past weeks has been very trying to the gardener with a lessened labour staff and probably a short water supply, all too common in the country. One might possibly sow and transplant from boxes or frames small numbers of such as Cabbages and Lettuce, but Carrots, Turnips, and Spinach cannot thus be dealt with, and these are each severally of much importance in the kitchen. W. STRUGNELL.

NOTES AND REPLIES.

Sowing herbs.—Kindly tell me what kinds of herbs it would be advisable to sow this autumn?—OLD SUBSCRIBER.

[It would, we consider, be useless to raise herbs from seed this autumn, as not only would the plants be too immature to stand the winter if planted out, but the risk of losses from damping off, etc., when placed in a frame or cold pit would be so great as to render the proceeding not worth the trouble. It would be far better to wait till after the turn of the year, and raise the various species of herbs you are desirous of cultivating so that the plants will be ready for setting out early in May.]

Globe Artichokes.—The cutting of heads now being over for the season the plants should be relieved of their old flower-stems and dead leaves, and after cleaning the ground between the stools loosen the surface with a fork and then well soak the plot with water. Follow this up with a good soaking of manure-water. New growth will soon push up and the stools become fully furnished ere winter sets in, and capable of resisting ordinary frost without protection. Where Globe Artichokes do not winter well it is always advisable to take up a sufficient number of suckers with roots attached some time next month and pot them. They keep well if the pots are plunged to the rims in a bed of ashes in a cold pit and kept well ventilated in favourable weather.—G. P. K.

Pea Alderman.—Nominally 5 feet in height, Alderman has, during the present season, run up almost 2 feet more. This is partly due to the excess of moisture during the growing season, and partly to the fact that the variety was given an exceptionally good place on soil which had been very deeply trenched and well manured. The pods are, perhaps, a trifle coarse, but no fault can be found with the Peas, which vary in number from nine to eleven seeds per pod, and are large and well flavoured. Unfortunately, the Hawfinch, a bird at one time practically unknown in the district, but now fairly numerous, has begun to sample the pods. By the way, Autocrat, if sown about the same date, makes a capital successor to Alderman—that is, in a general way—for in some seasons Autocrat is capricious and is inclined to develop mildew.—W. MCG.

Winter Spinach.—The prickly variety of Spinach generally used for autumn sowing is, like the round or summer Spinach, sown much too thickly. To have large and sturdy plants, not only should the bulk of seed sown be reduced, but, even so, thinning ought to be done. By this means the edible leaves grow to a larger size, the plants are not so apt to go to seed prematurely, and the plants are more robust and much better able to withstand the rigours of winter and early spring.—KIRK.

Hearting Kale.—While this variety is in some respects a most useful vegetable, I do not think that in Scottish gardens it will ever successfully compete with the old Curly Kale. The leaves are coarse in texture, albeit large, and they do not possess the hardness which is the chief characteristic of the older Kale. A severe winter would, I fancy, prove more fatal to the Hearting than to the Curly Kale, and for that reason it is wise to limit the planting.—SCOT.

Lettuce Henderson's New York.—In this we have a Lettuce of considerable merit. A Cabbage variety, it matures in a comparatively short time, is crisp and well-flavoured, and lasts in good condition over a long period. Even in hot weather the percentage of plants which bolt is very small. This Lettuce attains to a very fair size, and I think is one of the best all-round varieties in cultivation.—KIRK.

PLANTS AND FLOWERS.

OUTDOOR PLANTS.

THE LOSS OF THE CLEMATIS IN GARDENS.

THE Royal Horticultural Society may be in some degree responsible for the teachings of its lecturers, and it gives its agis to their conclusions in any ease. Mr. A. G. Jackman has read a paper on the Clematis before the Society, and he has not made the great question as to their frequent

hardy; eelworms and fungi do little harm; bursting the cells through excessive moisture is unusual; too much food does not hurt them; grafting, which is put last, is really the worst offender. Mr. Jackman says: "Grafting cannot be the cause, as my experience is that within a few weeks after the plant has been repotted it commences to form 'own' roots, and is then mainly supported by them and not by the roots of the 'stock.'"

This is not the case, as anyone who buys and plants may prove. In my Clematises, purchased from various nurseries, I wash

Then we come to Clematis Jackmani, and the author tells us that this was raised by his father. The plant is really the Niphon Clematis, found by Dr. Savatier on the rocky hills of the Island of Niphon. The account of its hybridisation is not credible. The plant is figured under its right name of hakonensis in Lavallee's book, "Les Clematites à grandes fleurs." M. Lavallee was a trustworthy grower of these plants, and his book is worthy of attention by anyone who would look into their history. It is embellished by true drawings of the Japanese kinds.

As to grafting, Mr. Jackman, whom I saw in his nursery over forty years ago, used to layer his plants, the only right way. But the young men coming on in following generations found the old way not quick enough for them, so they went on the hills and got the wild Clematis and grafted on that Japanese kinds—a fatal and cheap way.

It would be wrong to say that it is the only cause of disease. After the grafting, the mistake is setting the plants out fully exposed to the sun. The nature of the Clematis in the wild state is to run over bushes and copses, as one can see on the shores of Northern Africa. So if we plant beneath a bush it gets a little shade, and though the growth is not so free as when the plants are set apart, the life of the plant is longer and the effect is more beautiful. Lastly, more dangerous than eelworms and fungi are slugs, which bark the fragile stems as far up as they can get, and that means the death of the shoot in summer, but not the death of the plant if on its own roots. Lastly, lawn-mowers, hoe, or rake may smash the delicate stems if the plants are set out singly.

A correspondent, after reading the above, writes:—

"As to the name C. Jackmani. Even if it is the same thing as C. hakonensis the name C. Jackmani must stand for it, as it was first described under that name by Van Houtte in 'Fl. des Serres xvi' (1865), C. hakonensis being used by Franch and Savatier in their 'Enumer. Plantæ Japonicæ' considerably later. C. Jackmani was, of course, grown earlier than 1865, for it flowered in 1862 and got a first-class certificate in 1863 at Kensington."

P.S.—No publication of wrong description and wrong name should justify its use. The flora of Japan should be known to both Japanese and European botanists, and whether the plant is a natural species is a question of easy solution. To call such a beautiful plant a garden hybrid is to give an exaggerated idea of the value of hybridisation itself.—W. R.

Two sets of roots of Clematis on the same plant; upper one of the large Japanese Clematis, lower of our native Clematis Vitalba. Plant of a number bought recently at Barr's nursery at Taplow.

failure any clearer. It is the most beautiful family of climbing plants known, and yet, with hardiness and every charm, Clematises are rarely seen in gardens in the place they deserve. What should have been the essential part of the lecture, viz., the sudden "dying off" of the Clematis, Mr. Jackman gives as the probable causes of (1) frost; (2) eelworms or fungi; (3) the bursting of the cells through excessive moisture; (4) too rich food; (5) grafting. Now, none of these things is the true cause of the great losses of Clematises in British gardens. The plants in my garden are

out and find two distinct sets of roots, one that of the native Clematis and one that of the plant we wish to raise. The grafted plant is usually a plant of China or Japan, more fragile than our European wild kind, and being put on the root of our native kind, as strong as any Brier, it is reasonable to expect that the native plant will be the death of the graft in time, just as the common Quick kills American or Asiatic Thorns grafted upon it. Moreover, the nursery cultivation, which does not let the plants mature, is not the best way to study the question.

SWEET PEAS.

I HAVE read "Kirk's" note in the issue of August 12th (p. 402) with much interest. Two years ago I wrote in a similar vein but then drew cultivators' attention chiefly to the disease of Sweet Peas and the coarseness of the blooms as a result of the excessive manuring and disbudding of young side shoots meted out to the plants. At that time I could not help contrasting the crop of Sweet Peas in the garden of a friend who grew solely for exhibition and the one in my own garden grown for the supply of cut flowers under very ordinary treatment. His blooms were only available for about six weeks; then the plants shrivelled up, while my plants flowered all through the summer till the first week in October. The individual blooms were of medium size, highly coloured, and fragrant, and the foliage was green. The haulm was cleared away. I think much kindness has in many inst

sulted in the undoing of the Sweet Pea. If part of the labour expended on it were devoted to other kinds of flowers the general effect in the garden would be much more satisfactory. The clump system of growing Sweet Peas is to be commended, as they can be used in conjunction with other kinds of hardy border plants with charming effect. I well remember a cultivator telling an exhibitor that he could not compete with him then, but he would be able to do so two months later. By that date the exhibitor would not have any flowers to gather. Growing for exhibition is well enough, and instructive so long as the plants are not over-grown and the flowers rendered useless through coarseness. For purely garden decoration I am afraid we still sow the seeds too thickly. G. G. B.

Lupins from seed.—In the garden of Mr. Thomas Fraser, Maxwell Knowe, Dalbeattie, there has for some years been a wonderful display of Lupinus, raised by Mr. Fraser from seeds. Mr. Fraser's interest in the Lupins dates from some eleven or twelve years ago, when he observed the failing shown by most of the white herbaceous Lupins of dropping some of the flowers. The effort to overcome this by raising seedlings without this defect led him to take further interest in these flowers, and ultimately to try and secure a yellow variety of *L. polyphyllus*, by hybridising it with the yellow *L. arboreus*. In both of his aims Mr. Fraser has been successful, but he has ventured further and raised a vast number of varieties of many colours and shades, blue, yellow, white, purple, grey, bluish, and other hues abounding either alone or in striking combinations.—Ess.

Iris sibirica will do very well in a dry border, although it is not perhaps quite so vigorous as in a moist place or treated as suggested by "W. O.," on page 341. The Siberian Iris is easily raised from seeds sown in the open as soon as ripe or under glass in spring. I have a good many plants which have been grown from seeds, some of these being exceedingly handsome, with broad, well-coloured falls. Some of the white varieties are much superior to others, and selection is desirable.—DUMFRIES.

Gaillardia grandiflora.—For many weeks a large group in my garden has been lovely. If a few spray stakes are placed amongst them early they will grow up through these and need no other support. I find it pays to sow seed of this every year about midsummer, pricking the seedlings off into good soil and planting them into their flowering quarters in November. These young seedlings are far more vigorous than old plants.—DORSET.

Geum miniatum.—I am very fond of all the Geums, and this is a very good one for the rock garden. It is not so rampant as some, and, moreover, the flowers last much longer than those of many of the other Geums, the petals being of a stouter texture. It is a profuse bloomer, the blossoms being of a rich orange-red. Like all the members of this family, it is easily propagated by division of the clumps.—N. L.

Phlox Tapis Blanc.—Those who find pleasure in the dwarfer members of a race replete of tall-growing varieties may be glad to hear of this good white sort, which rarely attains more than 18 inches high. By reason of dwarfness, however, its sphere of usefulness is for garden purposes somewhat curtailed, though it might well figure in the small garden or as a marginal plant to the taller growers.—E. H. J.

Gypsophila elegans.—A light and graceful hardy annual, this is quite as elegant and useful as *G. paniculata*, and by successional sowings from March till May plenty of useful flowering material is available until the later *G. paniculata* comes into bloom. Thin early and sowing thickly, otherwise the plants will be weak and the display fleeting.—KIRK.

INDOOR PLANTS.

PARIS DAISIES.

(*CHRYSANTHEMUM FRUTESCENS.*)

Those who need pure white flowers early in the season should not forget the Paris Daisies. It is surprising the quantity of blooms that can be cut from a well-grown plant during the winter and early spring months. The great value of the Paris Daisy begins when the last Chrysanthemums are cut and the supply of white flowers is at a very low ebb. It is quite easy to have a constant supply of this flower from January onwards if the plants are prepared for this purpose during the summer months. Those who have any small plants remaining from bedding out should at once put them into 6-inch pots, as it is of the highest importance that the pots become crowded with roots by the end of the summer. When this is the case the plants get a foundation of hard wood, which increases the flower productiveness by 50 per cent., and the plants remain more dwarf and compact through the spring months. They cannot have too much sun, and should have the flower-buds pinched out until October. The old *C. frutescens* is the most free growing of the family. Halleri is not so leafy but produces more blooms in the space, and has grown much in favour with market growers. The value of Paris Daisies for summer decoration is well known, the plants being of the ordinary bedding size, but if readers wish to see this plant at its best they should use specimens three years or more old, and which have developed a tree-like habit.

On taking charge of a garden many years ago, in France, I found in 16-inch pots a number of specimens which were some ten years old, and had stems the size of a walking-stick. Such plants placed in the centre of a bed, or used as dot plants on the Grass, are impressive. They can be lifted in the autumn and potted, and although they may droop a bit, they will revive and be as good the following year. The value of the double white variety for cut bloom is very great, especially for wreath making, and those who have this kind of work to do should bear it in mind. Very early in the year the flowers are apt to come semi-double with a dark centre, but later on they are fine and very double. I have been using them for wreaths this season for the first time and found them most useful. This variety is not so vigorous as the single-flowered kinds, needs more culture, and does not strike so freely at the time when bedding plants are propagated, as the wood is apt to be rather wiry, and succulent cuttings are difficult to get from flowering plants. Plants put into rich ground and not allowed to bloom will yield soft shoots, and they ought to be struck a week or two earlier than the singles in order to allow a longer season of growth, which is needed if good plants in 4½-inch pots are desired for early summer decoration, as root action is comparatively weak.

Paris Daisies can be wintered quite safely in cold frames so long as they are guarded against hard frost. My cuttings were wintered in ainery under hand-lights. They were struck in small pots, taken out and shifted into 4½-inch pots, and made good specimens. They did not cost a penny for fuel. J. CORNHILL.

NOTES AND REPLIES.

Adiantums with long stems.—Can you tell me the best way to grow long-stemmed fronds of *Adiantum cuneatum*? I have tried potting them and starving them also, but with no suc-

cess. They are grown ininery under Vines. The stems are only 5 inches or 6 inches long in large pots, those in smaller pots are much shorter.—ADIANIUM.

[We regret being unable to tell you of any method whereby the length of stem can be increased to the extent you desire. Growing the plants in a heavily-shaded house with a moist and high temperature would cause the stems of the fronds to lengthen considerably, but it would be at the expense of the fronds, as these would be so fragile as to be practically useless, especially when cut for decoration. The best way to attain your purpose would be to grow those species of *Adiantum* the stems of which are of a considerable length even when the plants are grown under ordinary conditions. The treatment necessary for *A. cuneatum* will answer equally well for these.]

Double Ivy-leaved Pelargonium Kathleen Bunyard.—This is a very fine Ivy-leaved Pelargonium, and one that promises to take the market grower's fancy. The foliage is good, which is more than can be said of some of the other scarlet varieties. One of the first of this colour was Emile Lemoine. It was followed by several others, of which one, known as Scarlet Crousse, was for a time thought highly of. It, however, had no points in common with the well-known pink-flowered Mme. Crousse, which is so extensively grown. If Kathleen Bunyard takes the fancy of market growers, which appearances suggest it should, we may then expect to see it grown by thousands. The ways of the market man are, however, difficult to fathom, in proof of which I may mention that a few years ago one of the large growers was very much taken with some of the newer Ivy-leaved Pelargoniums. He grew a considerable number of each, but he assured me that they would not sell so long as he had any of the varieties Galilée and Souvenir de Charles Turner left. These two, with Mme. Crousse, form the most popular varieties of the present day. They are all very old kinds, having been sent out in the eighties of the last century, the most recent of the three being Galilée, which was distributed in 1887.—K. R. W.

Asclepias curassavica.—This *Asclepias* is in many parts of the tropics a troublesome weed, the silky wings with which the seeds are furnished enabling them to drift a considerable distance. In this country it is somewhat tender, but well worthy of cultivation as a greenhouse plant. The flowers, which are borne in terminal umbels, are orange-scarlet in colour. In the greenhouse its flowering extends over a very long period, and the same remark applies if it is planted out during the summer. Where fully exposed to the sun the flowers are brighter than when they develop in a shaded structure. Cuttings strike readily, and seedlings may also be raised in quantity. In winter the plants should be kept moderately dry and cut back to good eyes in the spring before they commence to grow.

Hibiscus Cooperi.—I first made the acquaintance of this plant a good many years ago in the conservatory at Mollance, Castle Douglas, in which, although strictly speaking a stove plant, it did well enough. For a *Hibiscus*, *H. Cooperi* is rather a small-growing plant, bearing its carmine flowers during the summer months. It is, however, attractive at all seasons by reason of its handsome foliage. Its leaves are of a deep shade of green, flaked and striped with white and rose. *H. Cooperi* may be effectively used for furnishing a back wall in a lean-to stove, and it is equally useful when grown in bush form.—W. McGUFFOG. *Balmæ.*

Freesias.—A hatch of *Freesias* will now be potted up for early flowering. They are shaken out from their flowering pots and the largest selected for putting into 5-inch and 6-inch pots, placing ten to twelve roots in a pot. They enjoy a light, rich compost with plenty of coarse sand.

ROOM AND WINDOW.**SOUTHERN HEATH IN THE HOUSE.**

This we find quite nice for the house; beautiful in colour and keeping well. We have already said so much about it of late that there is no need to enlarge more fully on such a precious plant.

FINE-LEAVED PLANTS IN THE HOUSE.

The finest of all plants grown for their foliage alone is undoubtedly the

ASPIDISTRA. There are other things as good—some perhaps more so—but the Aspidistra is a plant for everyone, and appears to be quite independent of the conditions which, in the case of things usually grown in rooms, are more or less indispensable. It requires no sun, very little air, and when stood in the corner of the room, where it does not get the full

was altered. This form requires plenty of light when growing, with only just enough shade to prevent the leaves being scorched. Grown in the house it must be kept in a window, not stood in an obscure position, and it must not be potted in rich compost, but just loam and leaf-soil in equal proportions.

THE INDIA-RUBBER PLANT is more difficult to keep in health, the trouble being to retain the lower leaves intact; in fact, this cannot be done indefinitely, as it naturally grows into a low tree of branching habit. The best way is to keep it until it becomes too tall for a window, and has a good bit of bare stem, and exchange with a florist, who is generally glad to get such plants for propagation. The leaves of the India-rubber are very leathery, and a healthy plant in a 4-inch or 6-inch pot can be kept several years in good condition if well cared for. In the first place it must

respectable retailer that it has come straight away from an expert grower. Given a plant that has been thoroughly well grown and that has never been exposed to adverse influences, the foliage will remain intact and retain its fine colour for several years.

ARALIA SIEBOLDI is wonderfully hardy; in fact, in the warmer counties it succeeds fairly well in the open ground, but, owing to the spread of its foliage, it is most suitable for good-sized bay windows. Like the Aspidistra, it can be maintained in good health when placed in a good-sized apartment where considerably removed from the direct influence of light and air. It is a good thing for corridors and entrance halls, as it does not fear draughts and variations of temperature.

GREVILLEA ROBUSTA is, perhaps, the most elegant of fine-leaved window plants. The erect, stiff habit and much-divided

Sprays of the Southern Heath (Erica australis) in a vase.

light, the colour of the foliage deepens. Not only is this the case, but it can be kept in the same pot without change of soil for several years, in fact it does better in this way than where it is frequently repotted. There is one thing in connection with this plant that should be borne in mind. Repotting or division should never be done until the young growths are a couple of inches long, as if shifted when at rest the plants will sulk and it may be the end of the season before young growths appear. The variegated variety thrives very well in a room, but in the course of time it reverts to the type. I daresay that some of your readers have come across old specimens which here and there show traces of variegation. These plants were in all probability quite variegated when young. I know they will go in this way. I have had them lose the white and recover it when the treatment

not be exposed to hot sun, and if kept during the winter in a constantly heated room the leaves must be sponged very frequently. I would strongly advise your readers never to purchase the plant from the hawkers who sometimes bring it among other things of a more hardy nature. The chances are that it has been away from the comfortable quarters where it was grown and has for a week or more been exposed to weather influences. Some plants, when thus treated, do not show the check experienced at the time, but the seeds of decay are sown, and, to the surprise of the owner, premature decay sets in, one leaf after the other turning yellow and dropping. The owner thinks he has been guilty of negligence, whereas he is quite innocent. My advice is, do not indulge in the luxury of an India-rubber unless you can buy one where it has been grown, or can take the assurance of a

foliage make it very attractive, and it can be kept in good health for a long time if well attended to in the way of watering and cleansing. It should be taken out occasionally and well washed with the rose or syringe.

ACACIA LOPHANTHA is of graceful growth, the bright green feathery foliage being very attractive, but it is of rapid growth, and, unless repotted annually when young, loses the bottom leaves. Therefore it is not a plant for windows of very moderate dimensions unless plants in 4½-pots are purchased every other year. If grown along into an 8-inch pot it may remain in good health several years, and nothing looks nicer where there is room in an apartment. When it begins to look shabby the best thing to do is to put it in the open ground for the summer and start again with a young plant. Not many, perhaps, have grown the

STAG'S HORN FERN in the house. It is a capital thing, very quaint and distinct, and apparently impervious to the atmospheric influences that obtain in a living-room during the winter.

CYRTORIUM FALCATUM is nearly hardy and good for corridors and similar places, and Asplenium bulbiferum and Pteris are two of the best room Ferns we have, as they may be kept in the same pots for several years without loss of beauty. Weak soot-water is good for them.

J. CORNHILL.

WINDOW PLANTS.

OLD-FASHIONED WINDOW PLANTS.—I often wonder what window gardeners of a past generation would think, could they see the display of Zonal Pelargoniums, Fuchsias, Paris Daisies, Begonias, etc., which can be made nowadays. Sixty years ago the window gardener had to be content with a very modest show, but some of the things then much favoured might well be grown at the present time. The Partridge-breasted Aloe (*A. variegata*) was a great favourite, and blooms freely when cared for, its distinctly variegated foliage being ornamental all the year through. The Mother of thousands (*Saxifraga sarmen-tosa*) is a fine basket plant and so easy to grow. The Hop plant (*Origanum*) was very frequently seen in cottagers' windows. Tom Thumb Fuchsia, a minute kind, is seldom seen nowadays. The Ice plant (*Mesembryanthemum*), the common Musk, the Rat's-tail Cactus (*Cereus flagelliformis*), a really fine thing when well grown (I once had a specimen in a basket, which annually produced quite a hundred blooms), several other kinds of *Cereus*, and the Candle plant (*Cacalia*), more curious than ornamental, perhaps, but of very simple culture, may also be mentioned. The old Musk was a great favourite, and the yellow *Mimulus* was in much favour. Another prime favourite was the *Auricula*, which some grew very well, and it is to be regretted that it is not much in evidence nowadays. It is a capital plant for the window-ledge, and, blooming early, can be taken away in time for the summer occupants.

EARLY-FLOWERING CHRYSANTHEMUMS.—The value of these is becoming more and more realised. They come just at a time when something is needed to keep company with the Michaelmas Daisies, and help to fill the void which autumn rains and frosts create. By the end of September the summer occupants of window-boxes are practically over. The Zonals and Fuchsias, which have done good work all through the summer, have come to the end of their tether, and this is the time when some nice plants of the early-blooming Chrysanthemums will be found very useful. Young plants put into 6-inch pots any time in June will be of the right size for window decoration. If propagated early in the season they will be too large unless they should be needed for entrance halls, corridors, or apartments of considerable dimensions, in which case the cuttings must be struck in February or early in March. The Desgranges family (white and yellow) is excellent, but there are many excellent varieties, this section of the family having been much improved and added to in late years. Intending growers should procure the list of some specialist, where they will find descriptions, including height, which is important, as the dwarf-habited kinds should be selected. I am sure that window gardeners would be pleased with these early-flowering Chrysanthemums, as they fill the void created by the sudden collapse of the tender plants.

BYFLEET.

GARDEN FOOD.

CHERRY RIPE.

I AM afraid I am in the same case with a great many people, as I never get any Cherries, although I have planted many. The birds get the fruit of the standard trees, and my wall-trees flower but do not fruit. I fear the soil and the situation are against them. It is a great pity that such a beautiful fruit as the Cherry should not thrive better than it does, and yet a large area of our country and Ireland must be well fitted for it where the soil suits.

The beauty of the Cherry should be taken into account. In countries like France and northern Italy, where the birds do not have it all their own way, the beauty of ripe Cherries is quite extraordinary, and the pleasure of getting them off the trees with the leaves attached is great. In our country, when the soil suits, it would be wise, perhaps, to depart a little from the wall business and develop the standard tree a little more where there is any hope of keeping the birds away. Having hunted Covent Garden without finding any ripe Cherries, in despair, I wrote to Mr. Bunyard for a sample, which I was glad to get, and he favours me with the following reply:—

For a dozen for garden use I recommend the following, arranged in order of ripening:—Early Purple Guigne, Early Rivers, May Duke, Governor Wood, Elton, Black Heart, Black Eagle, Waterloo, Black Tartarian, Bigarreau Napoleon, Florence, and Windsor. If only Royal Duke would fruit better it is, to my mind, most desirable for dessert and cooking; a true "Cerise," the jam made therefrom a revelation. Personally, I like all the soft flesh Cherries best.

W.

CULTURE.

Next to growing Cherries under glass, the best method, and the more certain way to obtain fine, handsome, thoroughly-ripened fruits is to grow the trees on walls. Excellent fruit is, of course, to be had from trees in the open, but owing to the inability of affording them adequate protection as soon as the fruit commences to ripen, it is seldom the latter is found to possess the same tenderness of flesh and rich flavour, neither does it approach in size examples ripened under glass or against a wall. The reason for the first named deficiency is readily explained because Cherries, when they commence to ripen, prove so irresistible to blackbirds, thrushes, and starlings that they have to be gathered while but partially mature in order to avoid, as a rule, a pecuniary loss. This is why the fruit as sent to, and seen in, the markets invariably lacks the essential qualities found in well-ripened samples. The same trouble has naturally to be contended with when the trees are grown against a wall, but in this case the difficulty is more easily overcome, as they can, at very slight cost, be netted so that the produce may hang unmolested until it has reached maturity. If wall space is available it is possible to have a supply lasting from the middle or end of May until the middle of August, by growing suitable varieties on walls varying in aspect from that of due south to north-west, and in favoured districts due north. On the first-named position should be grown such early maturing varieties as May Duke, Ludwig's Bigarreau, Guigne d'Annonay, Early Rivers, Frogmore Bigarreau, and Belle d'Orleans. Mid-season varieties to succeed those previously named, and consisting of Governor

Wood, Elton, Kentish Bigarreau, Bigarreau de Schrecken, Archduke Bigarreau, Noir de Schmidt, and others if desired, should have a position facing south-west. For a west and north-west aspect Bigarreau Napoleon, Black Tartarian, Bigarreau Noir de Guben, Emperor Francis, Noble, Waterloo, and Late Duke are a few suitable varieties which, of course, may be added to if accommodation for more exists. For a wall facing due north any of the early and mid-season kinds can be grown with success. With regard to

Soil, this, if unsuitable, must of necessity be made to answer the requirements of the Cherry, which are much the same as that needed for the successful cultivation of the Peach and Apricot, for instance. When very bad it should be excavated and a border or stations consisting of suitable compost substituted for it, the latter being the least expensive from a financial and labour-saving point of view. Heavy soils can easily be rectified by an addition of burnt soil and lime rubbish, the latter being very essential, while a moderate quantity of $\frac{1}{2}$ -inch bones and bone-meal will afford all the manurial aid the trees will require until they become established. For light and sandy soils a dressing of marl or clay, after it has been dried and reduced to a fine condition, will render them more holding and of suitable consistency. Here again bone manure will afford both a stimulant and the needful quota of lime. Where it can be spared or had for the digging new loam should not be omitted in either case, using as much of it as the circumstances of the case may appear to demand. Animal manure of any kind should be shunned as this only leads to the production of rank growth which fails to ripen properly. The right time to use such is when the trees come into bearing, and then only as a surface mulch, the properties of which will then be washed down to the roots by the action of rain, and in dry weather by artificial waterings.

Where the drainage is naturally good, and water passes quickly away, nothing further in this direction is needed, but when the subsoil is retentive of moisture, or if water is inclined to gather at a depth of 2 feet, it is useless to think of growing Cherries in such a position until it is properly drained. In ordinary circumstances the difficulty can be got over by putting in a good layer of brickbats or similar material, which will render the stations or border warm and dry and keep the roots out of harm's way.

FORM OF TREE.—What are termed fan-trained trees are the best for training on walls, and care should be taken when planting to see that they are not put in any deeper in the soil than they were when growing in the nursery. This remark, though applicable to the planting of all kinds of fruit trees, cannot be too strongly emphasised in regard to the Cherry. When the trees in due course come into bloom protection should be afforded in the same manner as for Peaches and Apricots, as the flowers are very tender. Black-fly is an enemy to be guarded against in spring, and to which special attention must be paid, otherwise the young growths and foliage quickly become crippled, which, besides affecting the current season's crop, ruins the prospects for the ensuing season. Tobacco-powder when fly first puts in an appearance, and later on Quassia extract, are the two best remedies, the first to hold the attack in check until the second can be safely applied. As soon as the fruit commences to colour clear water only should then be used for cleansing the trees.

A. W.

TREES AND SHRUBS.

ZENOBIA SPECIOSA.

I HAVE often had this plant and starved it in various kinds of loamy soil. The growth in the sun is very poor, and in clay soil, too. It is a native of the woods in Carolina, where the natural soil is mostly composed of dead leaves. At Hillbrook Place it is in a half-shady position. The place for the Zenobia in our gardens should be with American plants in peaty or leafy soils always.

SOUTH AMERICAN BARBERRIES.

MANY of the truly evergreen Barberries are natives of the Western Hemisphere, the pinnate-leaved species being freely represented in the northern portion of America. In the southern part of that

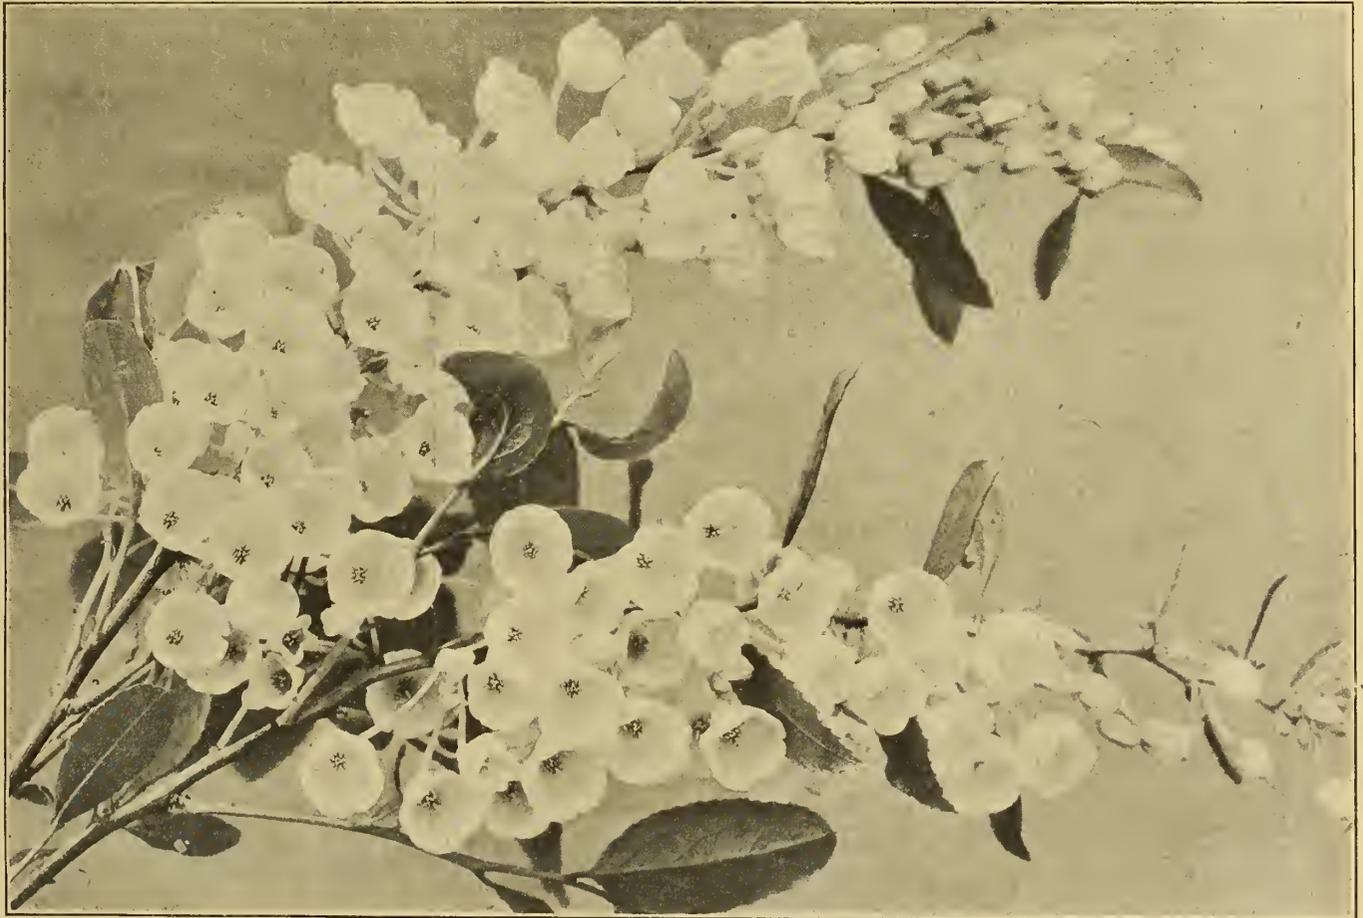

it flowers in May and is far more suited for the rock garden than for the shrubbery border. The blossoms are of a golden-yellow colour and freely borne.

BERBERIS HAKEOIDES. — One of the most distinct of all Barberries, and when seen at its best decidedly ornamental. It is of loose growth and under favourable conditions will reach a height of 10 feet to 12 feet. The roundish, hard-textured leaves, spiny at the margins, vary considerably in size, the largest being each over 2 inches in length. An interesting feature is that on the lower part of the specimen they are borne on long leaf-stalks, which gradually shorten till at the top of the shoots the leaves are almost, if not quite, sessile. The yellow flowers are small, but borne freely in dense, rounded clusters in April and May. Until the dispersal of the collection a fine specimen

actinacantha, *B. heterophylla*, and *B. ilicifolia*, but they are rarely met with.

BERBERIS STENOPHYLLA.—This claims mention with the South American Barberries, for though it originated as a chance seedling in this country its parents are conclusively proved to be *B. Darwini* and *B. empetrifolia*. It first appeared in the nursery of Messrs. Fisher and Holmes, of Sheffield, in the early 60's of the last century. It is commonly regarded as in beauty superior to *B. Darwini* itself, the habit of the plant being very graceful and the flowers borne in the greatest profusion. Its hybrid origin is shown by the fact that if seedlings are raised they often revert to the parents, chiefly to *B. Darwini*. K. R. W.

Tamarix pentandra.—In some gardens this is better known as *T. hispida aestivalis*, a name under which it was dis-

Zenobia speciosa at Hillbrook Place.

continent are to be found some desirable simple-leaved species, among them being one of the finest flowering shrubs of an evergreen nature that we have in this country. This is

BERBERIS DARWINI, whose orange-yellow flowers are borne in great profusion in April and May, while often during the autumn a second crop is produced. The spring blossoms are succeeded by berries which are a kind of bluish-black when ripe, and furnished with a bloom like a well-finished Grape. This Barberry is so readily raised from seeds that it is now one of the commonest of shrubs, for it readily adapts itself to our climatic conditions, far better, indeed, than most other natives of Chili.

BERBERIS EMPETRIFOLIA is, compared with the preceding, quite a miniature species, for though of spreading habit, it only reaches a height of about 18 inches.

(one of the original plants) stood in the Coombe Wood Nursery.

BERBERIS BUXIFOLIA, also known as *B. duleis*, is a rather stiff, erect-growing shrub that attains to a height of 6 feet to 10 feet, or even more. It is less of an evergreen nature than the species previously named, as in the event of a severe winter it loses most of its leaves. The yellow flowers are borne singly and hang suspended by long stalks. They develop earlier than any of the others, being often expanded quite early in April. There is a very curious dwarf form (*nana*) which forms a rounded tuft of foliage but rarely flowers. This Barberry is in a state of Nature spread over a considerable district, occurring as it does from the Straits of Magellan northwards to Valdivia.

Other South American species are *B.*

tributed by a French nurseryman a few years ago. Under normal conditions it forms a large bush or small tree after the style of *T. gallica*, but in gardens it is usually grown as a bush, cutting back the younger shoots during winter or spring to within a few buds of the base. Following this treatment, strong plume-like branches, each 2½ feet or 3 feet long, are formed by the end of July. These are clothed with dainty, bright-green leaves, every side branch on the upper two-thirds of the shoots bearing slender cylindrical racemes of pretty, rose-coloured flowers. The flowering period is from the middle of July throughout the greater part of August. To succeed with this shrub a sunny position on the outskirts of a lawn should be chosen and several plants should be placed together. Give good loamy soil and prune before the middle of February. The best method of propa-

gation is to take cuttings of ripened shoots 9 inches to 12 inches long in October or November, and insert them firmly in light, loamy soil out-of-doors. They should be allowed to remain undisturbed until the following autumn.—D.

Solanum crispum.—This flourishes in some of the south-western gardens of Scotland, and generous masses of its purple-blue flowers are to be seen in several places. Nowhere, however, have I seen it thriving so well as in Sir Herbert Maxwell's garden at Monreith, where big bushes give myriads of flowers in their season. In colder districts it requires a wall.—S. A.

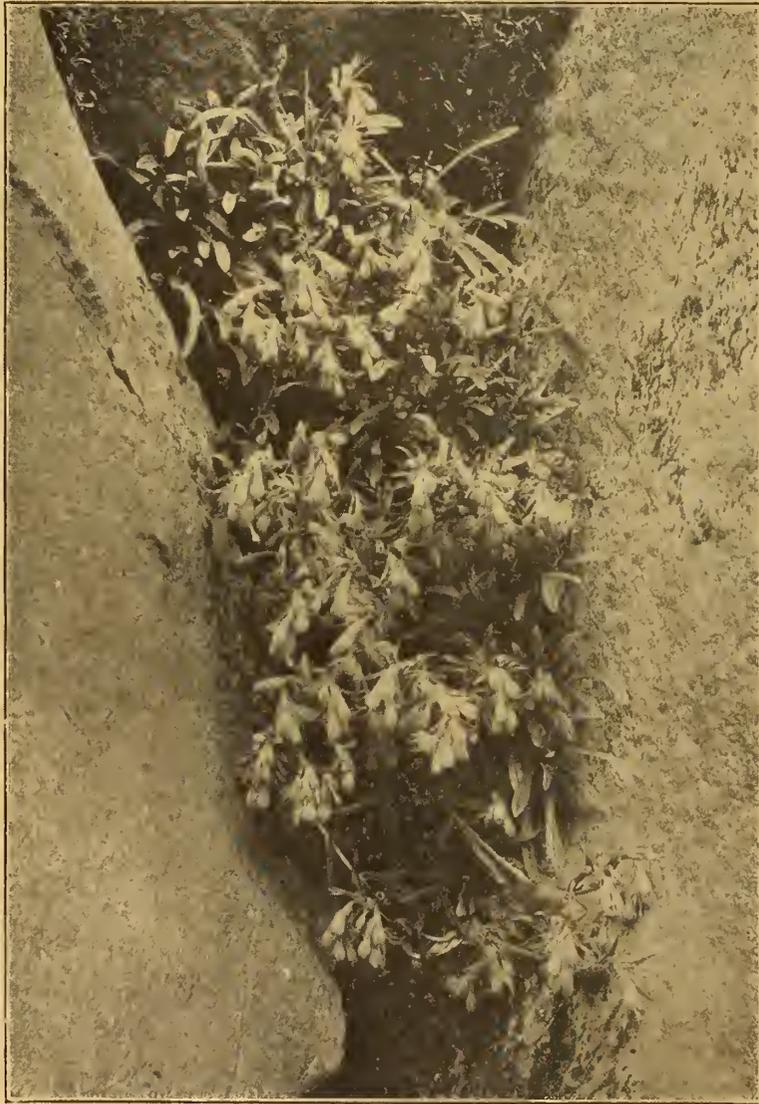

The Rock Roses.—The hardiest of the Cistuses with me is *C. laurifolius*, which will

sion. It is of vigorous growth, growing 6 feet high, flowers freely, and—in this district, at any rate—is not affected by spring frosts. The white blooms are produced in roundish clusters. Like others of the family, *S. bracteata* does best in a deep loam, and relishes a rather damp situation.—W. McG.

ROCK, ALPINE, BOG, FERN, AND WATER GARDENS.

THE GOLDEN DROP (ONOSMA TAURICUM).

This is one of the most beautiful of Borageworts, and one of the best and most free-flowering of all alpine plants. Per-

The Golden Drop (Onosma tauricum) in a deep crevice in the rock garden at Friar Park.

stand even more hard weather than *C. salvifolius*, which appears to come next in hardness here. *C. ladaniferus* is successfully grown in some of our south of Scotland gardens, but has suffered severely in bad weather. *C. purpureus* has pulled through some winters, but cannot be written down as hardy here.—S. ARNOTT, Dumfries.

Bryanthus erectus.—This is in bloom for the second time this season, although it has not so many of its pleasing flowers as earlier in the year. Planted in peaty soil at the base of a rock garden, it does very well with an almost due northern exposure. The pretty reddish-lilac, bell-like flowers go well with the varieties of St. Dabeoc's Heath, especially with the white variety.—DUMFRIES.

Spiræa bracteata.—Among the shrubby Spiræas, *S. bracteata* is well worthy of inclu-

fectly hardy, free-growing, profuse in flowering, bearing drooping cymes of golden blossoms that are delicately fragrant, it is a plant worthy of a good position in any garden. Its chief enemy is damp or a waterlogged condition of the soil. The plant dislikes manure. Plant it where a deep crevice—as in the illustration—is available for its roots, and, if possible, where its leaf-tufts may rest well above the surrounding soil, and the plant will give but little trouble. In sandy and light soils, generally, it is content on the level ground, though even here a few stones about the collar to keep the tuft free of the damp in winter are beneficial. Now is the best time to increase the plant, selecting as cuttings the

fresh bits of growth that can be torn from the stem with a heel attached. Such as these, in a cool and shady frame or hand-light, root readily.

NOTES AND REPLIES.

Lychnis Lagascæ.—This is one of the choicest plants for a retaining wall and has been flowering freely for many weeks with me. It likes a sunny, sheltered position, and must not be crowded up in any way with stronger-growing things. Its glaucous foliage and delicate pink flowers are lovely just now, and if it is in a dry position it will live and flourish for a long time. It ripens plenty of seeds, from which it can easily be increased, but there is a seed-feeding caterpillar which will clear most of the seed-pods in a night if it happens to be in the neighbourhood, so if seeds are required the plant should be watched, and if there is any sign of the caterpillar having been at work a visit with a lantern after dark will reveal the culprit. The same caterpillar will also work havoc with the seed-pods of any *Dianthus*, although its natural food is the seed-heads of the wild *Lychnis* and *Silenes*.—N. L.

Androsace lanuginosa.—A good grower of alpine plants tells us that this is the "tenderest of the lot," but this statement requires some qualification. It objects to winter wet and has also a curious way of going off without apparent cause when it has attained large dimensions. I have a photograph of a big plant from an English garden. This had been established for some years, but, unfortunately, a year or two later it died. Here we have a trying climate for plants which suffer from winter wet and spring frosts, but one of *A. lanuginosa* has survived these trials for eleven years, even though in some seasons it has not received the protection of a sheet of glass which it deserves. It likes a sunny place and a dry soil, with the protection of a piece of glass in winter and plenty of air.—DUMFRIES.

Platycodon Mariesi.—Maries' variety of *Platycodon grandiflorum*, the Balloon Flower of Japan, is much admired at this season, either in the bud or when the blooms are fully open. It is dwarfer than *P. grandiflorum*. Unfortunately there appears to be some ground for the complaint that the *Platycodons* are difficult to keep in winter, and there is a pretty wide consensus of opinion to this effect. Some attribute this to mice or slugs attacking the fleshy roots and destroying the young growths. Possibly the cause is wet in winter, as I find that *P. Mariesi* does much better in the moraine than anywhere else. As a late-flowering rock, moraine, or front border plant, *Platycodon Mariesi* is worth consideration. The white variety is very beautiful.—Ess.

Ramondia pyrenaica.—Apropos of the capital illustration and accompanying note on *Ramondia pyrenaica* on page 343, it is not generally known that the *Ramondias* make excellent wall plants, even on walls where there is but little soil in the chinks between the stones. Some notable examples of *Ramondias* on walls have come under my observation, none more interesting to me than in the Trinity College Botanic Gardens, Dublin, where the late Mr. F. W. Burbidge had established a number of *Ramondias* on a wall. Here they had seeded, and self-sown seedlings had appeared in some of the chinks.—S. ARNOTT.

"The English Flower Garden and Home Grounds."—New Edition, 12th, revised, with descriptions of all the best plants, trees, and shrubs, their culture and arrangement, illustrated on wood. Cloth, medium 8vo, 15s.; post free, 15s. 6d. Of all Booksellers or from the office of GARDENING ILLUSTRATED, 63, Lincoln's Inn Fields, London, W.C.

FRUIT.

THE EFFECT OF VARIOUS DRESSINGS ON PRUNING WOUNDS OF FRUIT-TREES.

EXPERIMENTS were begun in 1911 with different substances on pruning wounds of fruit-trees in order to determine the effect of the various compounds in accelerating the cure of the injury and their preservative action against the attacks of fungi and injurious insects. These experiments have been made on Apple-trees (as representative of the pome fruits) and on Peaches (as representative of stone fruits).

The following substances were employed:—White lead, white zinc (both mixed with liseed oil), yellow ochre, coal tar, shellac, and Avenarius carbolineum. They were applied, at different times of the year, to pruning wounds of various sizes, some newly inflicted and others of some weeks' standing. The effects were observed, both in the case of the treated wounds and in that of those which were left open, at the end of the first and second season of growth. The principal results were as follows:—

In all cases the untreated wounds healed more rapidly than those protected by any of the substances enumerated. Amongst the latter, Shellac seemed, during the first period of growth, to exercise a stimulating effect on the development of bark around the wound; this effect, however, ceased at the second period of growth. Shellac caused the least injury to the tissues of the cambium, but, on the other hand, it had the least adhesive power. Avenarius carbolineum and yellow ochre did so much harm to the cambium that, in the writer's opinion, they should never be used for covering pruning injuries. The lesion produced by coal tar was less serious, but this substance disappeared more quickly, owing to absorption and evaporation. White lead and white zinc also produce a slight injury to the cambium tissues when they are first applied, but these tissues soon recover, and at the end of the first growth period hardly any trace of injury is left. White lead and white zinc were the most efficacious of all the compounds used, and the former was the better of the two. Nothing is gained by waiting some weeks after pruning before applying the dressings.

All the substances used in the experiments in treating the pruning injuries of Peach-trees produced such damage to the wood that the wounds did not close. Consequently, these substances should never be applied to the wounds of the Peach; this probably applies to all other trees with stone fruit.

In no case were the wounds, whether open or protected, observed to be invaded by fungi. As the substances used seemed rather to retard the healing of the wounds it may be concluded that the treatment of injuries to the wood is, to say the least, useless. Nevertheless, had the experiments been carried further, it is possible that they might have exercised a useful effect upon the healing of very large injuries; this, however, still remains to be proved.—G. H. HOWE in *New York Agricultural Experiment Station Bulletin*.

The Aribaud Peach.—The Aribaud variety of Peach (obtained by Dr. Aribaud at Condrieu, Rhône, France) has, for some years, been much cultivated in the part of the Rhône valley lying between Vienna and Saint-Rambert-d'Albon. Owing to its vigour, as well as the shape of its fruit, this Peach should be undoubtedly classified among the American varieties and

comes probably from a plantation of 'Precoce de Hale,' of which the trees were used as grafting-stocks. The Aribaud Peach-tree is very vigorous and prolific; its fruits are very large, weighing on an average from 5½ oz. to 7 oz. (some Peaches weighed as much as 10½ oz.); they are well-shaped, round and very firm, and therefore travel well. It is a freestone. The colour of the fruit is fine, although of a duller red than in other varieties, the pulp is white, of excellent quality, and very juicy. In the above-mentioned region the Peaches ripen, on an average, between August 5th and 15th.

GARDEN PESTS AND FRIENDS.

Gooseberries diseased.—Will you please let me know what is wrong with my Gooseberries? These are only small berries, though I have some berries as large as pigeons' eggs.—GOOSEBERRY.

[Your Gooseberries are very badly attacked by American Gooseberry mildew. All such berries should be gathered and burned at once and the bushes should be tipped as soon as fear of growth in autumn is passed, the tipplings being carefully collected and burned, as it is upon these that the winter fruits are generally produced by which the fungus is carried over to another year. In the spring, about the third week in May, the bushes should be sprayed with Burgundy mixture so as to prevent the first outbreak of the disease. Notice of the outbreak must be given to the Board of Agriculture, Whitehall Place, S.W., under a severe penalty for neglect.]

Rose leaves unhealthy.—I should be much obliged if you can tell me what is the cause of enclosed leaves being as they are. They grow quite far apart, but all seem affected in the same way. What causes Roses to die—not many whole plants, but a good many in parts? They are not old—some three years or four years, and a few planted last autumn. All are dwarfs.—MRS. COSBY TRENCH.

[The Rose leaves appear to be attacked by one of the sawflies, and they should be sprayed with lead arseniate to prevent further ravages. There are many causes for the dying back of Roses, but it is much more satisfactory to us if specimens with information as to the nature of the soil in which they are growing are sent which will enable us to say definitely what the cause of the trouble may be.]

Red-spider on Peach-tree.—I enclose some leaves from a young Peach under glass, and will be much obliged if you will inform me what is destroying them, and the remedy. The tree was planted last year in place of one which apparently died from the same disease. There are several other Peaches and Nectarines in the same house which do not seem to be affected by it.—E. A. COX.

[The leaves you send have been attacked by red-spider. Your only remedy if the tree has fruit on it is to syringe freely with clear water, taking particular pains to see that both the under and the upper surfaces of the leaves are thoroughly wetted. Then, as soon as the fruit has been gathered, take 2 gallons of warm water, in which dissolve 3 oz. of soft soap. To this add 1½ oz. of sulphide of potassium (liver of sulphur), and when dissolved syringe the tree with the solution, taking the same care to see that the leaves are well moistened as when using plain water. If one application fails to destroy the red-spider, then repeat it. Also see to it that the roots have a thorough soaking of water, as very probably the soil in which the roots are is dry, this also causing the attack of red-spider. Next winter, when the trees are quite dormant, either dress with Gishurst compound or spray with caustic alkali solution.]

Mealy-bug on Ceanothus.—Will you kindly tell me the name of enclosed insect? It appeared on a Ceanothus (grown as a climber on the house, facing east) two years ago. Last year I had the Ceanothus well syringed with insecticide, and a large number of the insects were removed by hand; but this year they are almost as numerous as ever. The Ceanothus appears to be quite healthy and has made good growth this year.—(Miss) A. M. HALL.

[Mealy-bug is most difficult to move if once it gets a hold. The waxy, cotton-like secretion with which the insects are covered renders syringing or dipping almost useless, fumigation also is of no use. The best thing you can do is to carefully examine the plant, and remove every trace of the insect with a small, stiffish brush dipped in soft soap and water, and then in about a fortnight look over the plant again. The plant should be unfastened and the wall limewashed so as to destroy any mealy-bug or eggs which may be in the cracks.]

ROYAL HORTICULTURAL SOCIETY.

AUGUST 15TH, 1916.

THERE was a decided falling off in the number of exhibits at the fortnightly meeting held on the above-named date, in great measure due to the exhibition having once been cancelled and subsequently reinstated. In some directions this gave rise to indecision, which probably kept not a few away. The result was the smallest exhibition of the year, one almost entirely composed of hardy flowers together with a few Orchids. There were, indeed, no Carnations, Roses, miscellaneous greenhouse plants, or Ferns, an unusual state of things at this season. The finer exhibits were of Phloxes and Gladioli from Haywards Heath and Langport respectively, and in both there was much to admire. Interest, too, centred in a well-grown collection of ornamental Vines and other Chinese plants from Elstree. Only three novelties received recognition.

HARDY PLANTS.

From one of the most comprehensive exhibits of herbaceous Phloxes seen this year—there were upwards of sixty varieties on view—we selected the following because of their distinctness. Le Mahdi, among the blue or violet shades, is well known as an indispensable sort, though, perhaps, Dr. Charcot, in deeper blue, surpasses it. Braga (lilac, white eye) is also good. G. A. Strohleim, a most brilliant scarlet with crimson eye, is not surpassed by any. Baron von Dedem is also of scarlet colour. Meteore (salmon) and Europe (white, with carmine eye) also stood out well. Fiancé, Ant. Buchner, Lassberg, Tapis Blanc, and Mrs. E. H. Jenkins are all first-rate among pure whites, while quite distinct and desirable. These were from Mr. James Box, in whose collection an exceptionally dark purple Aconitum labelled "Spark's variety" was remarked. The most distinct plant, however, was Campanula primulæfolia, an erect-growing species whose pale violet-blue flowers are conspicuously marked purple at the base. It is an old species rarely met with in cultivation. In a small exhibit from Mr. W. Wells, jun., some new Delphiniums were noted, the best of these being the sky-blue, white-centred Merstham Glory and Mrs. Kaye (royal purple and rich violet). Both are semi-double, the latter possessed of large individual blossoms and handsome spikes on which the flowers are easily disposed. Rev. E. Lascelles was also on view, and is still unbeaten. In Collarette Dablias, a new set having broad outer florets encompassing others of small size, we regarded the variety Bonfire a great advance. Of brilliant scarlet, it is 4 inches across, and,

tilted at a slight upward angle, looks at one. For the attributes named it should be good in the garden. Messrs. Dobbie and Co. were showing it. *Sollya heterophylla* and *S. Drummondii*, the former the Australian Bluebell creeper, are rarely shown in a collection of hardy plants, though they are charming at any time. They were, however, shown in company with such as *Eucryphia pinnatifolia*, *Poterium obtusum* (a new Japanese plant having arching spikes of rosy-carmine flowers), *Desfontainea spinosa* (with crimson and golden flowers), a lovely lot of *Berberidopsis corallina*, whose tresses of globular scarlet flowers on crimson pedicels render it an attraction wherever seen. *Saxifraga manschurica* is a distinct novelty, with tall stems of inconspicuous white and pink flowers, said to be a bog-loving kind. It and others named above were shown by Mr. G. Reuthe, whose collection also contained the rare *Spiraea caespitosa*, the graceful *Astilbe simplicifolia*, *Magnolia fuscata*, and *Desmodium Dilleni*, whose branches are terminated by clusters of rosy-purple flowers. All are worthy garden plants.

GLADIOLI.

Only one collection—and that of great extent—of these was on view. From the wealth of novelties shown we selected Queen Mary (ivory-white, with huge velvet-crimson blotch), Loveliness (yellowish-blush, shaded with delicate pink, a really exquisite blend), Mrs. G. W. Willcock (pink and yellow), Flag of War, and Kelway's Masterpiece (both intensely crimson), with Golden Measure, Golden Ray, and Yellow Beauty. Some Langprin (*primulinus* hybrids) were also shown. All came from Messrs. James Kelway and Sons.

CLIMBING PLANTS.

A score or so of giant specimen trained plants in big pots of new Chinese Vines and other plants were sent by the Hon. Vicary Gibbs, Aldenham House, Elstree (gardener, Mr. E. Beckett). Of the *Vitis*, *V. armata* cyanocarpa and *V. Vicarii* were the most distinct, others of note being *reticulata* and *vitifolia*. Of *Clematis*, *C. Armandi* and *C. uncinata* are remarkable in foliage alone, the coppery-bronze of the young growth of the latter rendering it highly ornamental. Leaves of three species of *Gunnera*, *G. manicata*, *G. scabra*, and *G. Elwesi*, were shown, that first named the noblest of them all.

ORCHIDS.

Striking novelties of these in a group from Messrs. Hassall and Co. were the series of hybrids of *Cattleya Sybil* (aurca and iridescens), in which the most conspicuous variety was named Lord French. It has reddish or wine-coloured sepals, the lower half of the lip rich crimson, the upper half deep golden. The Duke of Marlborough gained an Award of Merit for *Cattleya weedonaurea*, whose rosy-mauve sepals and ruby-crimson lip render it attractive. Messrs. Charlesworth showed the very beautiful bronzy *Odontoglossum ardentissimum* Pintadeau and the new *Laelio-Cattleya Serbia*. For a graceful, pretty, and well-flowered specimen of *Odontoglossum aspidorrhinum* Mr. H. T. Pitt was given a cultural commendation. Messrs. Armstrong and Brown showed *Laelio-Cattleya Maqueda* and *Odontioda Cocksone*, the former a very dark-flowered variety, the more striking examples in a group from Messrs. Stuart Low and Co. being *Cattleya suavior alba* (very pure) and *C. Wavriniana* (rose and crimson).

A complete list of the certificated plants and medals awarded will be found in our advertisement columns.

THE WEEK'S WORK.

OPEN-AIR GARDENING.

IN BLOOM AUGUST 16TH.—*Androsace lanuginosa*, *Dryas octopetala*, *Veronica Lyalli*, *Linarias*, *Sagina glabra*, *Convolvulus mauritanicus*, *C. althæoides*, *Plumbago Larpentæ*, *Gentiana septemfida*, *Mimulus* (in variety), *Pratia Arenaria*, *P. ilicifolia*, *Arabis*, *Aster alpinus*, *Anthemis Kelseyi*, *Francoas* (in variety), *Primula capitata*, *Potentillas* (in variety), *Geums* (in variety), *Sedums* (various), *Dianthus*, *Statice* (in variety), *Tunica Saxifraga*, *Thalictrum Delavayi*, *T. dipterocarpum*, *Cerastiums*, *Bergamots*, *Helenium pumilum*, *Erodiums*, *Achilleas*, *Platystemon*, *Lobelia cardinalis*, *Gazania splendens*, *Agrostemmas*, *Erigerons*, *Helianthus* (in variety), *Eryngiums*, *Acanthus*, *Echinops*, *Galegas*, *Hollyhocks*, *Tritomas* (in variety), *Romneya Coulteri*, *Oenotheras* (in variety), *Montbretias* (in variety), *Centaureas*, *Herbaceous Phlox* (in variety), *Chrysanthemum maximum* (in variety), *Aster Amellus*, *A. Novi Belgii*, *Rudbeckias*, *Campanulas* (in variety), *Linums*, *Anchusas*, *Delphiniums*, *Meconopsis*, *Anemone japonica* (in variety), *Gladiolus* (in great variety), *Liliums* (in variety), *Gysophilas*, *Scabious* (in variety), *Hyacinthus candicans*, *Carnations* (in variety), *Sweet Peas*, *Roses* (many species), *Clematis* (in variety), *Honeysuckles* (late varieties), *Salvias*, *Stocks* (in great variety), *Pentstemons* (in variety), *Antirrhinums* (in many colours), *Sweet Sultans*, *Acrocliniums*, *Leptosiphons*, *Lavateras*, *Verbenas*, *Salpiglossis*, *Coreopsis* (in variety), *Godetias*, *Nigellas*, *Clarkias*, *Cosmos*, *Phlox Drummondii*, *Dianthus Heddeiwigi* (in variety), *Annual Delphiniums*, *Nemesias*, *Collinsias*, *Heliotropes*, *Ageratums*, *Calceolarias* (in variety), *Buddleias* (in variety), *Hardy Fuchsias* (in variety), *Ceanothus* (several), *Olearia Haasti*, *Rhus* (in variety), *Viburnum coriaceum*, *Veronicas* (shrubby) (in variety), *Calycanthus floridus*, *Magnolia grandiflora*, *Hydrangeas*, *Berberis Wilsoni*, *Spiræa Aitchisoni*, *Andromeda polifolia*, *Spartium junceum*, *Polygonums* (in variety), *Astilbes* (in variety), *Senecios*, *Epilobiums*, *Solidagos*, *Lysimachias*, *Lythrum roseum*, *Aponogeton*, *Arrow Head*, *Nuphar*, *Water Lilies* (in variety), *Flowering Rush*, *Cimicifuga racemosa*, *Verbascums*, *Nepeta Mussini*, *Hypericums*, *Jasminum affine*, *J. humile*, *Bocconia cordata*, *Catalpa japonica*, *Daphne Cneorum*, *Clerodendron trichotomum*.

THE WEEK'S WORK.—Up to the time of writing no rain has fallen in these gardens since July 17th, and almost everything has to be watered every second or third day. *Violas* have been denuded of their seed pods for the third time and other plants have needed similar attention. As soon as the flowers of stock-flowered Larkspurs begin to fade the spikes are cut off to encourage the formation of fresh inflorescences. *Pentstemons*, *Antirrhinums*, *East Lothian Stocks*, and many other plants are (as far as possible) given the same attention. The autumnal display of flowers depends very largely upon the treatment the plants receive during this month. The rock garden requires frequent attention as regards watering, weeding, and cutting off of spent flowers, also saving of seeds of choice subjects it is desirable to increase. This with a large collection is an important matter, as many subjects are short-lived. Where much watering has been done and the soil partially washed away from choice alpine, they have been given a top-dressing of fine soil to which plenty of coarse sand and grit was added. This will induce them to make fresh roots and the stock of choice subjects may often be readily increased by this means. The late-flowering varieties of *Deutzias* have been very fine. The flowers being now past, the shoots have been cut back to allow more space for the flowering shoots of next year. The plants are pruned so that flowers may be produced from the base instead of from the upper parts only, which they have a tendency to do unless corrected by judicious pruning. *Spiræa arifolia* and *S. Lindleyana* have also finished flowering, and these have been slightly pruned, merely taking out a shoot here and there to ease the plants where overcrowded. *Canterbury Bells*, *Delphiniums*, *Potentillas*, *Foxgloves*, and *Pyrethrums* raised from seed

sown last month have been pricked out into nursery beds on a warm border. It is necessary to shade the plants from the sun for a few days and water morning and evening.

F. W. GALLOP.

Lilford Hall, Oundle, Northants.

SOUTHERN COUNTIES.

Flower gardens.—To keep Zonal Pelargoniums with a minimum of trouble during the winter they require to be propagated early, so that they may be well rooted before winter sets in. The present is the best time to take this matter in hand, as the cuttings will now strike in the open either in boxes, pans, or dibbled into a border facing south. The box method gives the least trouble, as the cuttings, when struck, can remain in them till the following February or the usual time for potting off. The boxes should be filled with a mixture of loam and leaf-mould and then surfaced with sand. If the compost is passed through a ½-inch sieve the rougher portions come in for placing in the bottom of the boxes and over the crocks, of which but few, and those over the drainage holes, are needed. If the boxes are prepared beforehand the cuttings can then be inserted as fast as they are taken and made. Care must be taken not to spoil the appearance of the beds when this is done, labelling each variety correctly at the time to avoid having trouble in future in regard to nomenclature. If given a good watering at the time they will need no further attention for a week, if the weather is dry. If the cuttings are dibbled into a border the soil should be raked down to a fine condition and some compost of a similar nature to that named above added to the surface if the staple is in any way unsuitable. A dressing of pit sand will leave it ready for the reception of the cuttings, which should be dibbled in in rows 5 inches apart, the cuttings distant some 4 inches from each other. Soft-wooded and more tender subjects, such as *Heliotropes*, *Lobelias*, *Ageratums*, etc., should be struck in pans in a frame. From a good stock secured in this way any quantity can be propagated after the turn of the year.

Carnations and Picotees.—These must be layered without delay so that the resulting plants may be potted up and become well established before winter sets in; they will then winter well in a cold pit or frame.

Crassula coccinea.—This brilliant-flowered subject, useful alike for the embellishment of the greenhouse or for the filling of flower beds, should now be propagated. From four to five cuttings made from the top portion of the old plants should be inserted in 5-inch or 6-inch pots—four round the outside and one in the centre—filled with sandy compost. Being of a succulent nature, beyond that applied to settle the cuttings in position, water must be rather sparingly given afterwards until they are well rooted.

Pansies.—Seedlings to the requisite number must now be pricked out in a partly-shaded position outdoors or cold frames, the chief aim being to obtain good robust plants for the filling of beds and planting out in borders after the summer occupants get shabby.

Dahlias.—These now require all the time that can be spared in the way of thinning growths, staking, tying, and watering, if the hot weather continues.

Strawberry potting.—This should be got on with and brought to a close as soon as possible, so that the plants may have every possible chance of becoming established and the crowns ripened by the end of the autumn. Six-inch pots are quite large enough for the plants which will be forced early, but they may be one or two sizes larger for those intended for later work. Good fibrous loam should form the basis of the compost, adding a little well-rotted manure and lime rubble also in the case of heavy loam. Potting should be firmly done with the aid of the potting-stick, and when finished stand them in blocks in their several varieties in full sun on a hard base coated with fine cinder ashes to prevent worms gaining ingress. Until well rooted, the pots may stand fairly close together, afterwards sufficiently far apart for air to

circulate freely round them. Watering must have careful attention, and in hot weather the syringe freely plied over the foliage night and morning. When the roots commence showing at the crock holes, the pots should be moved round every week to prevent them from laying hold of the soil.

Figs.—The second crop being finished on early-forced planted out trees, all further shows should be suppressed, pulling off fruits which are of any size, and preventing as far as possible the further development of others by keeping the house as fully ventilated as circumstances permit. The roots, so long as the foliage remains firm and green, must have all the water they require, and to keep the former free from red-spider attack ply the syringe freely in fine weather. Root-pruning where necessary can be undertaken in regard to early forced trees by the end of the present month.

Marguerites.—Plants of both the single and double varieties which flowered earlier in the season and were subsequently cut back are now ready for a shift into larger pots. For these plants a too rich compost is a mistake. Firm potting is essential to free blossoming, while a little lime rubble added to the compost is also an aid in the same direction.

Cucumbers.—Plants which have been in bearing since early spring need every encouragement if they are required to continue yielding fruit until the end of the season—in the way of frequent top-dressings, stimulative waterings, thin training of the old bine, and the preservation as far as is needful of new growths. The crop should also be so regulated that too many fruits are not ready for cutting at one time. Plants exhibiting signs of suffering from eel-worms at the roots should be rooted out and burnt, there being no cure for this malady.

Tomatoes.—For winter supply a stock of plants should at once be raised either from seed or cuttings. Plants now in full bearing require plenty of stimulants and top-dressings, dispensing with all superfluous foliage in order that the sunlight may play freely on the fruit. To relieve the plants as far as possible, gather the fruits directly they become coloured, as they will finish on a shelf or stage.

A. W.

MIDLAND COUNTIES.

Early dessert Apples, such as Irish Peach, Gladstone, and Langley Pippin, will soon be ready for gathering. These early varieties of Apples will not keep long after they are gathered. The trees should be frequently examined with a view to picking off any fruits that are ready. They are best gathered before they are dead ripe, and only by careful judgment can they be sent to the table in their best condition, as they quickly lose their flavour and become mealy.

Apricots.—The crop is a very thin one. As soon as the trees are divested of the few fruits they are carrying they will be given a good washing with soapy water, and, as the roots are dry, the border will be given a thorough watering. Any secondary shoots are pinched back to the first leaf, and any robust shoots on young trees shortened, in preference to pruning them in winter.

Loganberries require much the same treatment as Raspberries. All the old fruiting growths should be removed as soon as they have been cleared of fruit to make more room for the young shoots for fruiting next year. Secure five or six of the strongest to the trellis or poles, according to the space available, to prevent their being damaged by winds, and apply liberal supplies of liquid manure or other stimulants to the roots. The same treatment should be given to Blackberries. Both plants being gross feeders, they require liberal treatment, especially when planted on light, poor soils.

Strawberries.—Continue to remove all runners as fast as they appear, and keep the soil frequently stirred between the plants. It is a good plan to set out a few rows of plants for supplying runners next season, whether for forcing in pots or forming new plantations. The ground should be well prepared by double

digging and manuring. Set out the plants in rows 1 foot apart, allowing about 9 inches between each. All flower-spikes must be removed throughout the season. During the present hot, dry weather fruit-trees on walls require daily attention in the matter of watering and syringing.

Hippeastrums.—As the earliest batch of these has completed its growth, and the foliage is turning yellow, water is gradually withheld and the plants exposed to the full sun in order to ripen the bulbs. At this period a lower temperature is advisable, and fresh air is admitted freely whenever the conditions permit. A quantity of Roman Hyacinths having come to hand, these are being put into boxes. I prefer to use boxes in the early stages of growth. It is a very easy matter to make them up into pots or bowls before they come into flower, taking care to select bulbs of the same size and stage of flowering for each particular pot or bowl. By adopting this method the pots or bowls frequently present a better appearance when the plants are in bloom than when the bulbs are grown during all their stages in pots. The bulbs are started in ordinary cutting boxes, using a sandy, porous compost, placing the bulbs at a distance of 2 inches apart each way. After the boxing is completed apply a good watering and stand them in a position where 6 inches deep of ashes (that have been well exposed to the weather) may be placed over them until the bulbs commence to grow, at which stage the ashes should be removed and the boxes placed in an unheated frame. When the roots have begun to extend freely into the soil the boxes may be placed in a warmer atmosphere, as required to force the plants into flower.

Cauliflowers.—A sowing of Early London will be made at the end of the month to provide plants for wintering in a cold-frame. As soon as the young plants are large enough they will be pricked out into their winter quarters. When established air liberally to keep the plants as sturdy and as hardy as possible. Plants of this description will be better able to stand the winter, and will not be likely to suffer a check when planted out in spring.

Potatoes.—All early and second-early varieties of Potatoes will be lifted as soon as possible and the tubers placed in a dry shed from which the light can be excluded. It is not wise to make very large heaps or the Potatoes may become heated and their quality affected. Tubers for next season's planting should be selected and allowed to remain in the open for a few days before they are placed in their winter quarters. A shed where light and air can be freely admitted is the best place in which to store them.

Herbs that have been cut and dried for winter use will be stored away in a dry loft where there is a free circulation of air. If seed of Basil is sown now and the seedlings pricked off into pots as soon as they are large enough, the plants will furnish a plentiful supply of green leaves throughout the winter. Grow them in a temperature of 65 degs. Frequent small sowings of Chervil are made in a sheltered part of the garden, the plants being watered freely in dry weather. About the middle of September a good sowing of Chervil will be made to furnish plants for the winter, choosing a sheltered site where protection from frost and snow can be afforded. Plants of Sweet Marjoram set out about six weeks ago will be cut down to within 2 inches of the ground and allowed to make fresh growth before they are lifted and potted for winter supplies. The plants are wintered in a slightly heated frame, removing the lights during fine weather to prevent the foliage from damping.

Clearing up.—Continue to clear and burn all exhausted crops. The ashes will provide excellent material for dressing the soil later. Growing crops should be hoed frequently and watered as often as circumstances permit. Liquid manure is of great assistance to such plants as Celery, Leeks, Runner Beans, French Beans, and Cauliflowers. Late Peas must be afforded liberal supplies of water. Mildew is one of their worst enemies, and the best remedy is flowers of sulphur applied as soon as mildew makes its appearance.

Cucumbers for winter use should be planted without delay, so as to cover the trellis before it is necessary to crop the plants. The house should be thoroughly cleansed previous to planting, so that no insect pests may remain from summer crops. Very little air will be necessary, provided the plants are shaded on bright days. Keep up a humid atmosphere and encourage growth by frequent light top-dressings of loam and manure from a spent Mushroom bed in equal parts, with the addition of slight dustings of soot from time to time. This will give the foliage a dark green colour, and will also add to the colour and good appearance of the fruit. Avoid a high temperature by fire-heat, this in my opinion being the cause of more failures than many are aware of.

F. W. GALLOP.

SCOTLAND.

Flower beds.—Growth has been slow among bedded-out plants—indeed, the display is not general yet. The cold weather, accompanied by wet, which followed planting, gave the various subjects a check from which they were slow to recover. In such a season as this has been, no matter how carefully hardening off is done, there must always be a set-back to tender plants. With a renewal of heat, however, progress is being made, and, given favourable conditions during August and September, a good display may yet be anticipated.

Fruit picking is now in full swing, and occupies a considerable portion of the available time. No picking is done on damp days, and until the sun dries up the dew in the mornings the fruit is left alone. Crops of bush fruits and Raspberries are, on the whole, satisfactory, Gooseberries being decidedly later than usual.

Morello Cherries.—These are quite a good crop on old trees, but on younger trees the fruits have not stoned well. During the week it has become necessary to net the trees. Birds are numerous, and inclined to be destructive in respect of this crop; while, in addition, squirrels at times develop a fondness for these Cherries. This, I am inclined to think, is more for the sake of the kernel of the stone than for the pulp of the fruit. When these are numerous they soon do considerable damage, cotton nets being no obstacle to their sharp teeth.

Vines.—Unless attention can be given regularly at this time there will be an outbreak of insect pests. The best preventive of red-spider or of thrips is robust foliage, and this can only be obtained by strict attention to details, especially in the way of admitting plenty of air on all suitable occasions. Should red-spider attack the leaves of Vines upon which the berries are colouring it is a serious matter, for the syringe cannot be used, and the sponging of the foliage is an utter impossibility. Therefore, it pays to devote some time at close intervals to the needs of Vines, even if other work be pressing rather severely.

Winter-flowering plants.—Salvias and Eupatoriums which have been planted out ought to be inspected occasionally and pinched at intervals in order to induce a shapely habit. If the weather is at all hot or dry the roots must be kept moist either by watering or mulching. Genistas, generally grown during summer in pots, may, with advantage, be plunged. The roots by plunging are kept cool and consistently moist, while the plants retain their colour in a higher degree.

Cinerarias and Primulas.—These, too, must at this time be grown as coolly as possible. Cinerarias especially appreciate a slight shade during the middle of the day when the sunshine is strong. The leaf-mining maggot may at times be troublesome. On the first signs of an attack the plants should be looked over, and the intruders, which are easily detected in the tissues of the leaves, squeezed between the finger and thumb.

Chrysanthemums.—Owing to pressure of work in other directions the staking of Chrysanthemums has been somewhat retarded. The work, however, is being persevered with, and it is hoped soon to bring it to a conclusion. The pots being now full of roots, weak

liquid manure, varied by soot water, is of much assistance to the plants. An occasional change of stimulant may with advantage be given, guano or some concentrated fertiliser in solution making a good change. If top-dressing has not yet been done, it ought to be attended to at the first opportunity. Other work among Chrysanthemums at this time comprises the regular removal of side shoots and the securing of the stems to their supports. Should carwigs be troublesome they must be persistently hunted for until they are exterminated. Pots of small diameter inverted upon the stakes, with a little Moss in them, make as useful traps as anything else, although slices of Potato laid on the surface of the pots or in their neighbourhood have been found to be of some use.

Ferns under glass.—Now is the correct time at which to sow spores of Ferns cultivated under glass. Spores can, of course, be sown at any time, but those who grow a collection of Ferns will notice that the spores on the backs of the fronds are ripe, and therefore it is more satisfactory to sow now than in spring, when the vitality of the spores may quite conceivably be less. The soil must be in an equable state of moisture, as, if this is neglected after germination occurs, the seedlings will perish. Any young Ferns which require more pot room should be shifted on without delay. The Filmy Ferns and some others are very interesting, but they are not so useful in a general way as the majority of Ferns, for they cannot safely be employed in rooms.

Hardy fruit.—During the week summer pruning was brought to a close. Growth is satisfactory, being good but not excessive. Much depends on the weather from now till the end of September. If the conditions are favourable the wood will mature well. Trees carrying normal crops were well watered. It must not be inferred from this that those which have thin crops are being neglected. This is not the case; but, in the meantime, those which are more heavily laden are given precedence. As time permits, the work will be continued until all have been watered. Some thinning was done among young Appletrees on dwarfing stocks, which, differing from older and orchard trees on Crab, are bearing good crops. Mulches were given where necessary, both to these trees and to Pears.

Soil for cuttings.—Cutting time will again shortly be at hand, and a sufficient quantity of suitable soil of a light, somewhat sandy nature is being got ready in order to prevent delay when it is needed.

Autumn Onions.—During the week a full sowing of autumn Onions was made. More seeds than usual were sown. Sowing in heat during spring has to a large extent ousted the culture of autumn Onions; but owing to the scarcity in late spring of the present year in many gardens, autumn Onions will be more extensively sown than has been the case for years. A quarter which had carried a crop of early Potatoes was selected for sowing. Having been well manured for that crop, it was considered rich enough. No digging was practised, the soil was merely cleaned and levelled and made very firm. A distance of 14 inches was allowed between the lines, and sowing was done rather more thickly than in spring.

Spinach Beet.—At the same time a sowing of Spinach Beet was made. Leaves from this sowing will not be numerous during winter, but may be depended upon to keep up a supply during spring and almost until the end of June next season.

Cabbage seed was sown in bulk at the same time. Small hearting kinds are, as previously indicated, preferred, and plants from this sowing are more reliable than those sown previously. The latter will shortly be transplanted to nursery beds.

Curly Kale.—A small quantity of this to provide a few lines of plants in spring was also sown. These plants, although they go to seed early next autumn, are useful for providing a substitute for Spinach in the event of a hot, dry, summer. W. MCGUFFOG.

Balmæ Gardens, Kirkcudbright.

CORRESPONDENCE.

PLANTS AND FLOWERS.

Red-spider on Violets (L. W.).—Your Violets have been attacked by red-spider, due in great measure to dryness at the roots and neglect to keep them well syringed during the summer. Your only plan now is to syringe the plants well with Quassia extract, seeing to it that the leaves are thoroughly wetted on both sides.

Larkspur disease (M. B. Newman).—The disease on the Larkspur you send is the mould known as *Carospora Delphinii*, and you should at once root up and burn every plant. If possible, apply a lighted wisp of straw or paper to the plants where they stand in order to prevent the distribution of the mature spores, subsequently destroying the plant and not a little of the surface soil around by burning.

Mildew on Rose (J. S. Purden).—Your Rose has been attacked by mildew, due in great measure to the exposed position and the gravelly soil in which it is growing. Next spring, on the first signs of mildew, well syringe the plant with a solution of sulphide of potassium at the rate of $\frac{3}{4}$ oz. to a gallon of water, repeating this when it reappears. Rambler Roses, when trained on a wall, are very susceptible to mildew, the best place for them being an arbour or a pergola.

Asters diseased (M. B. Newman).—Your Asters have been attacked by a fungus common to these plants. Your only remedy is to pull up and burn all the affected plants and give the soil a good dressing of lime. This might be repeated next spring, though it were better to avoid the contaminated area and plant the Asters elsewhere. Where the attack is of a mild nature it may if taken early be checked by dusting the bases of the plants and the surrounding soil with powdered lime and sulphur mixed.

Oleander flowers failing to open (E. A. M.).—Oleanders will occasionally behave as yours are doing, some varieties being more liable to do so than others. The cause of it has given rise to a good deal of speculation, and it is generally considered to arise from the roots having at some time received a check, particularly in being allowed to get too dry, for, given thorough drainage, the Oleander is a moisture-loving plant. In the case of some large old plants that we once had we used to give them, about once a fortnight, a dose of weak liquid-manure, beginning just as the flower-buds were seen and the blooms opened freely.

Rose leaves spotted (A. G. C.).—Your Rose leaves have been attacked by a fungus known as Rose-leaf blotch (*Actionema roseæ*). The infested leaves should be picked off and burned, and if many leaves are affected the whole shoot should be cut away. Next spring spray with Bordeaux mixture when the buds are about to burst, and again in a week or ten days' time. The following mixture is also very good:—Take 3 oz. of carbonate of copper and make it into a paste with a little water, then add slowly a pint and a half of strong ammonia. This should produce a clear blue fluid, which dilute with 22 gallons of water before using.

Roses from cuttings (H. B.).—October is the best month to take cuttings, which should be procured from shoots that have flowered. They should be, if possible, from 6 inches to 8 inches long, the ripest and firmest being selected. When taking the cuttings it is well to remember that the nearer they are cut off to the old wood the better, all the leaves with the exception of one or two at the extreme points being removed. The soil should be of a sandy nature and made fairly firm, proper drainage being ensured. It is also important to choose a position where shelter can be afforded during severe weather. The plan of inserting some coarse sharp sand in each hole before putting in the cutting is a good one, and goes a long way to the formation of roots.

FRUIT.

Scale on Peach-trees (W. M.).—There is no insecticide we could advise you to use now your trees are advanced in growth that could

be said to be both safe and effective. You could soon reduce them with a pointed stick, going over the branches one by one. This is a practice we have often had recourse to in summer when scale that has escaped winter dressings makes its presence felt. The scale will be found mostly on the older wood now, and can be easily crushed with a thinly-cut piece of wood. It is better, because safer, to spend time thus than to run the risk of injury to trees and fruit with strong insecticides. Make a point of dealing with the scale after the crop is cleared.

MISCELLANEOUS.

Clover in lawn (Moreton).—Next spring try what a few dressings of nitrate of soda will do, beginning as soon as growth shows signs of starting. This will encourage the Grasses and enable them to stand up against the Clover. You may apply this at the rate (roughly) of 1 lb. to 2 lb. per square rod. Have you been using any manure on your lawn? We ask this question because it is well known that certain kinds—one in particular—have a tendency to encourage the growth of Clover, and as farmers like Clover in their pastures, this tendency is one of the reasons why they use basic slag.

PLANTS AND FLOWERS.

R. Nolan Ferrall.—Such protection as you refer to would be of no use, as when the haulm is destroyed the tubers would do no more good and might as well be lifted. Besides, August is too late to plant Potatoes.—M. F.—You may now cut out any of the weak and old wood that has flowered, but do not cut off the leaves. The "black, dirty stuff" on the leaves is probably due to mealy-bug, which may be also on other plants in the house, and so long as this pest is present you will never be able to clean the Rose. If such is the case, all badly-infested plants should be burned. The hardy slipper Orchids are best grown in the open air.—G. B. R.—You may cut the shoots back during the winter. Doing this will not stop its flowering. The only thing will be that the flowering will be delayed for a year. Do not use the shears—cut back with a sharp knife. It would, however, be far better if you could possibly allow the tree to grow naturally, as in this way its beauty will be emphasised.—C. Champernowne.—We cannot trace the plant you refer to in any book of reference we have. Kindly send us a specimen shoot of the same, and we will do our best to help you.—Pat, Dublin.—The best remedy in the case of the caterpillars is to persevere with the hand-picking. You might also try what syringing the plants with Quassia extract and soft soap will do. This insecticide will certainly clear off the green-fly.—Norah.—Please send specimens of the white insect you refer to.

NAMES OF PLANTS AND FRUITS.

Names of plants.—F. M. A. H.—*Campanula rapunculoides alba.*—How, *Halifax.*—Costrmary (*Chrysanthemum Balsamita*).—J. Knight.—*Echinops Ritro*, so far as we can say without leaves.—J. A. K.—Looks like a small bloom of *Arctotis grandis*. Please send better specimen in small box to prevent its being crushed.—Norah.—We cannot undertake to name Roses.—J. N. B.—*Mauve flower:* *Chelone Lyoni*; *Pink:* *Godetia var.*, please send better specimen.—Edwin Griffiths.—*Spiræa Douglasi*.

CATALOGUES RECEIVED.

LITTLE AND BALLANTYNE, Carlisle.—*Bulbs, Roses, Fruit-trees, etc.*, 1916.

SUTTON AND SONS, Reading.—*List of Bulbs for* 1916.

T. SMITH, Newry.—*List of Hardy Bulbs*, 1916-17.

Parcels sent to our office insufficiently stamped will, in future, be refused.

Bulb growers will oblige by sending early copies of their Lists and Catalogues to MANAGER, "Gardening Illustrated," 63, Lincoln's Inn Fields, London, W.C.

NURSERYMEN AND SEEDSMEN AS LANDSCAPE ARCHITECTS.

GOING up Hatfield way through the north of London roads last autumn, I saw, as one may often see, a board sticking out of a garden announcing occupier to be a landscape gardener; and now are seen bold advertisements of seedsmen advertising that they are ready to lay out gardens. The business of a nurseryman is a very useful and honourable one, and we are indebted to the great houses—such as Lee, Waterer, Veitch, and others—for what they have done for gardening in England; a man who keeps a good nursery in working order must be an able and busy one. But landscape design, in any bold sense as it would be carried out in a country place, is entirely outside his province. A man of genius may rise in the worst conditions, but the work of a nurseryman is so arduous and constant that it wants all his time and energy.

There is always the temptation for a nurseryman to put his own stock into any place he lays out, and he often does it with no niggardly hand. That ought not to be; all the plants in a place laid out in any spirited way should be under the control of an independent artist, just as the materials for building a house should be under the full control of the good architect. Some years ago I went to see a public garden made at the cost of six thousand pounds. It was not a big one, and it was almost completely filled with Privet, Laurel, and nursery rubbish planted there without artistic control of any kind. A good grower of a special race of plants may be trusted to plant them, but under artistic control. As to the question of the specially working in with other features of the place. Some of the most hideous things in British gardens are ill-formed rock gardens, bad for the plants and spoiling the natural landscape around. Often one sees ten stones used in such rockeries where three would have given a better result. That is why the character of the ground and the district should be studied by the designer of gardens, and there is a danger of letting the specialist come in to make too much of his own work.

Then we come to the seed merchant. His, also, is a very serious and important business, both at home and in examining his crops through half of Europe. His plants are grown in lines or plots, and his work is carried on usually quite away from beautiful country. The seedsman, more than the nurseryman, should keep to

his business—a very important one for all concerned.

Any person may call himself a landscape gardener, and many do so without the least knowledge of or preparation for it.

The men who practise landscape gardening do so very often in such a stereotyped fashion that one can see at once their stamp around any great city. This should not be, and it shows that no thought is given to the main thing—the study of the ground itself. Therefore the best way in the present state of landscape gardening is that each owner should think out the thing for himself, not hurriedly, but patiently. He will then, generally speaking, do better work than those people who profess to be landscape gardeners. We mean by "landscape" anything in the broad sense of picture-making, not a patch of ground in the suburbs.

"Landscape plans by mail" are now offered by a nurseryman in America, and also one in France. A surer way to get stereotyped plans could not be pursued. All this sort of design shuts out all study of the ground itself, the only thing that matters really in designing a garden.

Some nurserymen advertise themselves as "garden architects," a ridiculous term. Any walling or other essential stone work about a house or garden should be the work of a real architect, otherwise there may be a sad ending. The idea of a nurseryman or seedsman with pretensions to any kind of architecture is absurd.

W.

NOTES OF THE WEEK.

Primula nutans.—A lovely soft lavender Chinese mountain Primrose, flowers in a well-set powdered spike. The flowers have a delicate fragrance. Clearly a gem for the rock garden. From Messrs. Wallace, Colchester.

Yellow Gladioli.—A yellow series of these opens up a new interest as to the effects to be sought from this noble group of summer and early autumn flowers. By the good use of *G. primulinus* there are large as well as medium-sized flowers, all of distinct charm. They are not named but classed as yellows. From Messrs. Wallace, Colchester.

Rose Noella Nabonnand.—This Rose was very good in a Kirkcudbright garden I visited the other day. It was grown, as it should be, as a climber, and was giving a number of its immense, though not ungainly, fragrant, semi-double, rosy-crimson flowers. It is one of the hardiest of the

Teas and has been proved by long cultivation to be a satisfactory variety to employ as a climber for a trellis or arbour.—S. A.

Rubus arcticus.—This pretty miniature Bramble seems to like a fairly heavy soil in a cool position, where it runs about freely without becoming aggressive. It grows about 6 inches high and has pretty rose-coloured flowers followed by golden fruits which have a strong sugary perfume. The foliage colours up well in the autumn, which is an additional attraction to a really charming little species.—N. L.

Lilium Browni.—On page 413, in an article on Brown's Lily, I notice a statement to the effect that the entire bulb of this Lily is tinged with reddish-brown, and am wondering what possible authority the writer can have for such a statement, which is entirely contrary to the facts. The bulb of *L. Browni* is, indeed, very distinct from that of any other Lily, and one of its outstanding characters is that it is white throughout and has no suspicion of a trace of reddish-brown or any other colour at all on it. The proper name of *L. odorum* is japonicum Colchesterense.—A. GROVE.

Chrysanthemum maximum Caledonia.—Mr. William Angus, of Penicuik, who raised that standard variety of *Chrysanthemum maximum*, King Edward VII., was also the raiser of the above variety. Its flowers are fully as large as those of King Edward VII., but the ray petals have a slight tendency to reflex and are nicely lacinated, this making them much less formal. I have grown *Caledonia* since the year it was exhibited, and this year my plant is finer than ever, giving a great number of flowers. In some seasons the varieties of *C. maximum* have the purity of their flowers sadly defaced by flies, but this season there is much less of this than usual.—S. ARNOTT.

Spiraea Aitchisoni.—This, found wild in Afghanistan and Kashmir, is a very vigorous bush and may exceed 12 feet in height. The leaves, made up of numerous narrow leaflets, are each often 12 inches to 15 inches long. The white flowers are borne from the middle of July until September in long panicles, the larger ones exceeding 18 inches in length. No one who is unable to give this plant abundance of room should attempt to grow it, for it is only when well developed and given plenty of space that its full beauty can be seen. It is improved by a little pruning during late winter. At that time the previous year's wood may be cut back well beyond the

base of the flower-heads, the actual amount of pruning being determined by the vigour of the bushes. It is a good plan to remove old wood now and then when specially vigorous young shoots are available to replace it, for the finest inflorescences are from young wood. It is easily increased from seed.—D.

Potentilla dubia.—The dwarf *Potentilla*s are very useful for the rock garden, and this is one of the brightest. It is of quite neat habit and an easy doer in a sunny position in an open pocket of light soil. It spreads fairly quickly and seems more dependent upon an annual top-dressing to keep it vigorous than some of the other members of its family. It is easily increased by division, and a large patch of it looks very pretty when studded over with its bright yellow flowers.—N. L.

The Hollyhock disease.—It is disappointing to learn that the Hollyhock disease is again virulent. I have been much struck by the comparative immunity of a group of plants in a small garden by the roadside, where they are subjected in summer to clouds of dust. These Hollyhocks, which are old plants, suffer very little, and are quite healthy this summer. Possibly the dust has a deterrent effect, although it certainly detracts from the appearance of the plants and flowers. Those of us who were familiar with the Hollyhock ere the disease made such havoc recall with regret the handsome plants once so plentiful in gardens.—S. ARNOTT.

The Mummy Pea.—Will you kindly name the enclosed? A friend saw it last year growing at a railway station in Wales, and the station master gave her some seeds. Both thought it a Sweet Pea, but obviously it is not. The plant grows to a great height and the flowers are sweet-scented. Colour, standard white; keel, red.—M. B.

[The specimen you send is the so-called Mummy Pea. It is really the Crown or Cluster Pea (*Pisum sativum umbellatum*). The leaves appear at some distance apart on the lower part of the stem, but towards the top they form a kind of cluster, the stem becoming fasciated by producing a number of leaves from the axils of which the flowers issue. The Peas are smooth and of a light yellow colour. There are two forms of this Pea, one with white and the other with bicolor flowers (the latter being the one you send). Neither is of any value in gardens, and this Pea is only worth growing as a curiosity.—Ed.]

Phlox varieties at Kew.—One of the most attractive features at Kew at the present time (the middle of August) is a long border between the rock garden and Orchid-houses planted with varieties of *Phlox*, all of which are in full flower. The border is exposed to the west, but gets a good deal of sun during the greater part of the day. Unfortunately, the soil at Kew is too dry for these plants, and success is only gained by the addition of heavier loam to the sandy loam of the locality and by a liberal surface-dressing of decayed leaves each year, with frequent watering in dry weather. Amongst other varieties the following were noted recently as being in full flower:—*Steigler* (2½ feet, white, striated with pink, very fine heads of flowers), *Elizabeth Campbell* (a very pretty pink with lighter eye), *Tapis Blanc* (1½ feet, white, large, compact heads of flowers), *Voile de Feu* (scarlet), *Etna* (2½ feet, scarlet), *Miss Willmott* (3 feet, white), *Frau Antoine Buchner* (2 feet to 2½ feet, white), *Mrs. Jenkins* (white), *Selina* (rose, deeper-coloured eye), *Harrison's Seedling* (2 feet to 2½ feet, white, with a faint pink eye), *Cyrano* (3½ feet, lilac, with light marks), *Le Mahdi* (2½ feet

to 3 feet, rich purple), *Friefraulein von Lassburg* (2 feet, white), *Daniel Lesueur* (lilac, with white eye), *Iris* (rich reddish-purple), and *W. Watson* (1½ feet, rose, with darker eye). Whether seen in separate masses or in clumps in herbaceous borders, these *Phloxes* are amongst the most useful of late summer-flowering hardy plants, and few people fail to appreciate their charms.—K.

Pentstemon rupicola.—In all probability this beautiful and distinct Californian species is already in cultivation in many collections of alpine plants as *P. Davidsoni*, by which name it has been exhibited at the Chelsea Show of the Royal Horticultural Society for two or three years past, and by which name it will still be found in catalogues of choice alpine. It was so exhibited at the Chelsea show this year, and in my opinion constituted the most brilliant alpine of that great gathering. Imagine an inch-high sub-shrub having small glaucous, slightly toothed leaves and carmine-red, horizontally disposed tubular flowers, usually in pairs, and nearly 2 inches in length, and you have some idea of one of the sweetest of alpine gems, and for which no praise would be too great. Brilliant and effective in flower, and ranking high with the choicest of alpine, it is good enough for all, and if far from common is all the more desirable on that account. For a plant of such small stature it does well amid broken rock and loamy soil. It is also good for crevice work or in rock walls, where its roots can descend into well-prepared soil.—E. H. JENKINS.

Plans or Mother Earth?—This from Mr. J. W. Elliott, of Pittsburg:—

In the main I agree with what you say; but it is practically impossible for a landscape gardener to do his work—at least, in this country—without paper plans. If people were willing to pay liberally for his services so that he could afford to give the time necessary to the making of and carrying out the plans on the ground, I think this would be the better way, but people are not willing to pay such fees. I have been practising landscape gardening for some thirty years, and I think that you would admit, if you saw it, that the most of my work is good. I have always used paper plans, and could not have done one-fourth as much work without them; but I have made it a rule when the work was important and in "up-and-down country," as you say, to make the drawings for the plan on the grounds so that the bit of ground that would be treated was immediately under the eye of the draftsman. Then, again, the majority of clients demand estimates in advance, and it is impossible to give these without a plan and specification.

[For professional work and charges, the plan is essential, and for simple schemes in level prairie country or quite level, treeless land in any, it may serve. When it comes to the question of artistic results in an up-and-down land, like much of France and our isles, riddled with old roads, old trees, abandoned quarries, river cliffs or mountain rocks, and buildings of old time, then the plan can never do the work that close study of the ground itself may give. Also, some problems can only be solved by long study of the ground by one living on it for months. The vegetation, native or planted, may have considerable influence on design, hence the need of men versed in knowledge of these is essential. Otherwise, how are we to get the best results from any given spot of earth?—W. R.]

FRUIT.

FRUIT PROSPECTS IN SOUTH-WEST SCOTLAND.

THE general impression, gained by reports furnished by growers in south-west Scotland, is that, all over, fruit crops will be decidedly thin and under the average of the past few years. In some districts this is attributed to the unceasing wet which prevailed during the time that the trees were in bloom; in others it is said that a severe and unlooked-for frost which occurred on the night of June 3rd or the morning of June 4th is responsible. The following are details gleaned from reliable sources in the Stewartry of Kirkcudbright and the neighbouring Shire of Wigtown:—

STRAWBERRIES.—Generally later; crops medium; berries smaller than usual and deficient of flavour and colour.

RASPBERRIES.—Late, but, on the whole, a satisfactory crop, especially on heavy soil. The Raspberry moth (*Lampronia rubella*) has given more trouble than usual in many gardens.

CURRENTS OF ALL VARIETIES.—A fairly good crop. Black Currents are scarcer, owing to the attacks of mite.

GOOSEBERRIES.—The crops are variable, in some districts being of average bulk or over; in other places the yield will be much less than usual.

APPLES.—Like Gooseberries, the crop varies. In sheltered districts there will be a moderate but not heavy crop; in more exposed situations Apples are practically a failure.

PEARS.—The general reports indicate that the yield will be about half of the average. Some trees bear a heavy crop, others are barren. The Pear midge has been active in a few areas.

PLUMS.—The crop, generally, will be much lighter than has been the case for the past two years. Victoria maintains its reputation as a consistent bearer, but the finer dessert varieties are disappointing.

CHERRIES.—Sweet Cherries were, on the whole, satisfactory. Morello Cherries did not stone well, and will be but a moderate crop.

W. MCGUFFOG.
Balmae Gardens, Kirkcudbright.

STORING APPLES AND PEARS.

CAN you tell me how to store my Apples and Pears so as to prevent them from going rotten or shrivelling up as they did last year? They were laid singly on sheets of paper on the floor of a billiard-room on the top floor of the house, which is a newly built one. They all went bad in no time. I have a cellar, but it would not do as everything in it goes mildewed.—J. G. S. B.

[Immense loss takes place from want of thought in making the fruit-room, and Pears and Apples, our most important fruits, suffer the most. The common way of keeping fruit in dry rooms leads to early decay. The walls of the fruit-room should be thick; the windows should open to the north; the doors should be double, the outer door thick, the inner door not so thick. A ground floor over a cellar is the best, or an upper floor, provided it be not under the roof. The temperature should be uniform, and never much below freezing point. The shelves should be wood, and, if possible, of open work, so that the fruit can be aired on all sides. Fruit-rooms are often built in any convenient spot regardless as to whether the position is a suitable one, and their general character is frequently quite the opposite of what is required for keeping Apples and Pears over the longest possible period. In the first place, fruit-rooms should never have

a south aspect, nor yet be lofty. The reason for this is apparent, as the sun, especially during October and November, runs up the temperature to far too great a degree, the fruit ripens speedily, and is soon past and gone. Lofty structures become too dry, and thus also hasten premature ripening and speedy decay. The best fruit-room we know of is constructed behind a high bank of earth and facing due north. It is entered by descending several steps, and is covered by a heavy, thatched roof, ample ventilation being provided. A cool, even temperature is what is wanted to preserve fruit, and to enable late sorts of Apples to retain their weight. So long as actual freezing does not occur the fruit will take no harm in winter. We prefer to lay sheets of coarse brown paper over the

is a thorough knowledge of the variety, so that it may not be gathered till quite ready. Those without the convenience of a fruit-room might adopt the plan of storing in boxes, barrels, or tubs, leaving these open for a few days in order to let any moisture escape, keeping them closely covered and arranged one on top of the other in a cool loft or spare room. Never place straw or hay under Apples, nor use it for protecting them, as it quickly becomes musty and taints the Apples.

A very good fruit-room was that in the Royal Horticultural Society's Gardens at Chiswick, which was a lean-to built against a north wall. In this the shelves, which were in tiers, were latticed and ran from east to west, with a flat shelf running along the centre of the room on which

TREES AND SHRUBS.

THE REST HARROWS (ONONIS).

The Rest Harrows belong to the Pea family and consist of shrubs, sub-shrubs, and herbaceous plants, several of which are well worth growing in the herbaceous border or shrubbery. A familiar representative of the family is the common Rest Harrow (*Ononis arvensis*) of our commons and waysides, which is conspicuous during summer by reason of its many flowers, which are less brightly coloured, than those of several of the exotic species that may be grown. These species are natives of Southern Europe, their cultivation presenting no difficulty except in the colder parts of the country, where the more

The Shrubby Rest Harrow (Ononis fruticosa).

shelves when storing soft-fleshed, tender-skinned sorts, but firm, thick-skinned, long-keeping Apples do very well simply laid not too thickly on the bare shelves. Where there is plenty of space, the more thinly Apples are stored the better, as the greater the pressure the greater the liability to rot, and by thin storage faulty fruit is more easily detected, and the labour of sorting reduced. Apples will keep well in cellars, provided they have no windows facing south into which the sun can shine. It is not, however, the fruit-room or its construction that is all-important, but the

HARVESTING of the fruit at the right moment. All fruit that is to be stored must be carefully picked, as any bruising, however slight, quickly develops and eventually spoils the fruit. Another point

specimens of each kind were kept for reference. To enter it one had to go down three steps, and the floor was an earthen one. A path went right round the whole room, so that it was easy to get at any of the fruit when wanted. The windows were fitted with shutters, which, if the weather was severe, were always closed. We never knew frost to do any harm—in fact, during a period of thirteen years we never knew frost enter. The Apples were always kept on the north side, the Pears being on the south side. The fruit, both Apples and Pears, used to keep and ripen well. A great point we think in the proper keeping of fruit is always to have an equable temperature, the earthen floor going a long way towards this. The temperature in this fruit-store ranged from 40 degs. to 45 degs.]

tender ones are not hardy enough for outdoor planting. All are easily increased from seeds sown indoors in spring, and one or two specimens may be grown from cuttings.

O. FRUTICOSA, here figured, is an attractive little bush 2 feet or so high with deep pink or pinkish-purple flowers produced in erect clusters from early summer until the end of August. A native of S. Europe, it is said to have been introduced about 1680. As it is a sun-loving plant an open position is desirable, and it may either be planted in the front of a shrubbery or in the rock garden.

O. ARAGONENSIS is, perhaps, the most generally useful of the shrubby species. Introduced from the Pyrenees a hundred years ago, it is known here as a dwarf, rather densely-branched bush 1½ feet high,

with yellow flowers in erect racemes up to 6 inches long. The flowers, borne very freely during May and June, are attractive, especially when the plant is given a prominent position in the rock garden.

O. SPINOSA, though not really shrubby, is more shrub-like than the other British species. It is very common in many parts of the country, forming well-branched bushes up to 2 feet or so high, which bear pink flowers freely during summer. It is a good plant for waste land in either light or moderately heavy loamy soil, in addition to being one of those subjects that can be established on colliery waste heaps.

O. ROTUNDFOLIA grows about 1½ feet high and has soft, though persistent, stems and pink flowers which are larger than those of the other species here mentioned. It is found wild in Central and Southern Europe and is suitable for the front of the shrubbery, the herbaceous border, or the rock garden. D.

PLANTS AND FLOWERS.

CHRYSANTHEMUMS.

CHRYSANTHEMUM NOTES.

We will presume that all the plants are in their flowering pots and now standing in their summer quarters, being all securely fastened to stakes as supports. Twice a week the shoots should be gone over, tying those required to the supports, as those plants intended for large blooms make such rapid growth at this stage that neglect quickly causes disappointment in the loss of tops of new growth. It is at the time the plants have just made a new start into growth after the formation of the first break that they are more liable to snap off; the shoots being then so succulent, and being bent somewhat to get them into position, a broken shoot is almost sure to result if timely attention is not given to ease any ties in securing the growths. As growth progresses, shoots will sometimes appear a few inches above the soil and in many other places, owing to the dormant state of the buds when a complete check was given to the plant in growth. When the first flower-bud forms, nearly all joints at one time or another push out growths, and these must be removed as fast as they are seen. Pinching them out is the best plan. Of course, the removal of suckers must be carried out as fast as they are formed, as also must all weeds be removed which grow on the surface of the soil. Any dead or bruised leaves should be constantly removed, if only for the sake of tidiness.

Watering the plants properly is important—in fact, success or failure depends upon how this is carried out. It is wise, when possible, to allow one person always to take charge of the watering of the plants. He becomes accustomed to their wants, as some varieties need more than others. The plants should never have water applied to them until they require it, particularly when the soil is of a heavy character. Tapping the sides of the pots with the knuckles is the surest means of judging whether water is necessary or otherwise. During hot days in summer, water at the roots will be required, in some instances three times. Where rain-water can be had it should be used in preference to any other, but where it comes direct from wells or water companies' pipes in a cold state, as is often the case near towns, means should be taken to expose it to the sun and air some time previous to its being used. If used in a cold state a severe check may be given to the plants, as during hot weather the soil

in the pots is many degrees warmer than the water from the sources named. This mode of application gives a chill to the roots and accelerates the spread of mildew, which is hard to eradicate. Water which contains a large percentage of carbonate of lime in solution is hurtful to the plants and should be softened by some process before being used. Anticalcaire, more commonly called milk of lime, will precipitate the chalk to the bottom of the tank if mixed at the rate of 2 lbs. to 500 gallons of water. If thoroughly stirred and allowed to stand for twenty-four hours it renders the water soft. Common washing soda dissolved in a small quantity of hot water at the rate of ¼ lb. of soda to 35 gallons of water also answers as a stimulant to the plants. Water that is very hard should always be softened by some means before using.

Syringing the plants promotes a healthy growth and checks insects. Syringing is best done in the afternoon, or evening, of a hot day. It is only in bright weather that syringing should be done. Where the plants are numerous and placed in rows the garden engine is the best instrument to use, and the water should be directed to the foliage, both underneath and on the surface with some force, by going between two rows of plants and returning in the opposite direction. The plants then receive a thorough washing, which is better than a light sprinkle with the hand syringe. In the evening after a hot day is the best time to perform this detail, and again early in the morning, if the weather is hot and dry and without any dews. In cold, sunless weather, syringing the plants should not be practised, or mildew would be encouraged, and this ought to be averted. Insects should be eradicated upon the first signs of life. Search for Celery fly and earwigs. For mildew use black sulphur in a dry state sprinkled on the foliage. Beware also of the jumper fly.

GARDEN PESTS AND FRIENDS.

THE MUSTARD BEETLE ON WATERCRESS.

The following note has been communicated to the Board of Agriculture and Fisheries by Mr. A. Roebuck, Assistant Lecturer in Botany at Harper Adams Agricultural College:—

For some years past the Watercress beds on a Shropshire farm have suffered severely from the attacks of the mustard beetle (*Phædon cochleariæ*), the Cress plants being thickly covered with grubs or beetles from May to the end of the year, so that the leaves were completely stripped off and even the outer layers of the stems were also eaten away. The grubs occur only on the plants in the beds, but the beetles, in addition to occurring in dense clusters on the shoots standing out of the water, are also found all over the sides of the beds and in the field and hedges round about. They shelter in crevices of bark and in hollow-stemmed weeds through the winter. On the slightest alarm the beetles drop to the ground. The insects cause considerable monetary loss by seriously curtailing the cropping season. The Cress on this farm is grown for marketing from March to June. The general progress of attack is as follows:—The first sign is the arrival on the beds of the beetles at the end of April or beginning of May. They have in the great majority of cases walked the short distance across the field (1 yard to 20 yards) from their winter shelters under loose bark, crevices of palings, hollow stems of weeds, etc. Towards the end of May the Cress leaves begin to

vanish rapidly and the plants become covered with large numbers of the grubs, which soon render further cropping impossible. Few beetles are seen about the end of May, but more appear in June, and from then to the cutting back of the plants both beetles and grubs abound. Although there is considerable overlapping, apparently there are at least two broods on the Cress during a season, the beetles of the first brood appearing approximately in the middle of June and those of the second towards the end of July. From the beginning of July, when most of the beds have had the plants finally cut back for new shoots to form, the larvæ have all left the beds and the beetles move into the field and hedgerows. The pupæ may then be found in little holes in the banks above the surface of the water, especially round the roots of Grasses. The beetles soon emerge from these and swarm over the beds and sides until these are cleaned out. They are to be found during the autumn dotted over the ground or clustered on various plants, chiefly on the hedge side of the beds, but as the cold weather appears they take up their more sheltered winter quarters.

TREATMENT.—It seems probable that if the following measures be taken the beetle may be so held in check that it is no longer a serious pest:—

(1) On the appearance of the beetles for egg-laying in May the beds should be flooded, the plants being stirred continually to keep the beetles in the water. Rubbish should be put round the beds to catch the escaping beetles. The beetles usually collect at one end, when they can be taken off in buckets and destroyed. After a final stirring of the plants the water may be run off and the rubbish around burnt. (2) Should any larvæ make their appearance towards the end of the month the beds should again be flooded to get the grubs to the surface of the water and away from their food for a few days. After about a week the water may be run off. (3) If the beetles collect on the beds in July another flooding would be necessary. Where the sides project above the flood-water they should be pared about 1 inch to throw any contained pupæ into the water. Cut weeds and old Cress stems put round the beds collect large numbers of beetles. These may then be burnt or buried deeply. The beetles may again be taken out in buckets. After about a week the water may be run off. This will kill also the pupæ in the sides of the bank. (4) After a severe attack attention might be given to the removal of as much winter shelter as possible. Much good might be done by cutting down the weeds, especially hollow-stemmed ones, and Grasses, cutting them low down to the ground; keeping hedges trimmed and cleaned, preferably using wire fencing or good tarred palings (stakes with bark on should never be used); and not allowing the cleanings from the Cress beds to lie about and rot on the ground, since the hollow stems afford admirable shelter. All these cleanings can be left for a time round the beds to collect as many beetles as possible, and then should be burnt during the winter or early spring.

BRIEF DESCRIPTION OF PHÆDON COCHLEARIÆ.—The grubs or larvæ, which appear on the plants in large numbers from May to July, are of a smoky-brown colour, somewhat hairy and spotted with black. They have six legs towards the head end and a caudal foot or pro-leg. When full grown they are not quite ¼ inch long. They are widest about the middle of the body, tapering towards each end. Along each side is a row of tubercles, from which they can protrude a yellow gland. The pupa, formed at the last moult of the larva, is

bright yellow in colour, with a row of blue spots down the centre of the back. The body is broader and slightly shorter than the larva and is slightly curled in on the underside. The small undeveloped wings and legs can be seen tucked in on the underside. These pupæ are hidden just under the surface of the soil around the sides of the beds. The perfect insect is a shining blue or green beetle of an oblong-oval shape and about $\frac{1}{2}$ inch long. The thorax and wing cases are minutely punctured, the latter in lines parallel to the length of the body. These can only be seen under a magnifying glass. The antennæ, legs, and under-surface are black.

NOTES AND REPLIES.

An uncommon fungus.—I enclose a sketch (life size) of a very curious fungus, which I should much like identified. I have never seen

course, interfere with the drainage; the ants are running over the plants in the hope of finding aphides. The only remedy that we can suggest is to find out where the nest is, and then, if it is in such a position as to render it possible to do so, to open it with a spade when all the ants are within for the night, and thoroughly soak it with boiling water, which will kill every ant with which it comes into contact.

ROCK, ALPINE, BOG, FERN, AND WATER GARDENS.

PRUNELLA WEBBIANA.

WHILE the Self-heals have little claim to be regarded as first-rate among herbaceous plants, as these are known to-day, the best of them are still possessed of distinctive attributes of their own which, with a moderately generous treatment, ensure for

spikes is ensured, that let alone flowering earlier—probably also better—than the divided group. There is a variety called rosea, and another grandiflora with rich violet-purple flowers. Alba has whitish flowers, but it is less effective than the rest.

E. H. JENKINS.

VEGETABLES.

CROWDED PLANTING.

THE errors of close planting are more apparent in the kitchen garden than probably anywhere else. It is generally in the smaller gardens where this mistaken economy is practised to the greatest extent. That the system cannot be too strongly condemned we have almost daily proof, for where the various crops are so crowded together the sun and air, which

Part of a group of Webb's Self-heal (*Prunella Webbiana*) in the rock garden at Friar Park.

anything the least like it before. It came up in one night, and was quite faded the following evening. The drawing gives the colour and form. It had eight legs, all joined by a rim of the same thickness on the top. On the inner side of the legs a liquid brown matter oozed out. This had a very strong smell of a dead animal and attracted numerous flies. The fungus was very brittle and inside was full of cells resembling a sponge. Perhaps you could identify this species for me and return the sketch at your convenience.—KENNETH McDOWALL, Logan, Straunraer.

[The fungus you send drawings of is *Clathrus cancellatus*, a very beautiful but exceedingly foetid fungus, generally found in woods, but not very common. It is, we think, figured in Cooke's "British Fungi" and in Masseur's "Mon. of Gastromycetes.]

Ants on Chrysanthemums (A).—The ants will not injure the plants at all unless they make their nests in the pots. This would, of

them a place in the front of the border or in the larger rock garden. Easily cultivated and soon forming goodly patches, they well repay annual or biennial division and replanting, which, while admitting of the fullest development, is also responsible for a more abundant display of blossoms. Spring (March and April) is the best time for the work, though in this the plants are by no means fastidious. That named above is one of the showiest of these plants, and, seen in a considerable mass, its purplish-crimson flowers are distinctly effective. Less than a foot high, the finer display is produced during June and July, though often enough a profusion of spikes is maintained into September. To some extent methodical cultivation and division assist this. That is to say, given two groups, by dividing and replanting one each year a longer succession of good

are so beneficial and desirable, cannot perform their allotted functions.

The first error of this crowded planting is generally seen in the seed-bed as regards those crops which have to be transplanted elsewhere, such as Lettuce and the various Brassicas. In the majority of instances the same amount of seed spread over three times the quantity of ground would produce plants which would defy the drought of summer, and also the cold of winter. Where Lettuces are sown thickly the plants soon become crowded together, and instead of forming sturdy little plants, the main stem lengthens to such an extent that the formation of hearts is an impossibility, and the plants quickly run to seed. The more widely disposed the plants are the better they will be able to successfully withstand frost and damp, for during a wet time this latter is almost as destructive as frost,

and where the plants are crowded together these often remain damp for days together. Take the Brussels Sprout as an illustration. It is impossible for this to prove profitable with close planting, for, hardy as it is, damp is often answerable for more failures than frost, and the more sheltered the garden the greater is the precaution necessary to avoid planting too closely together. During a warm and wet autumn the plants keep on growing until very late in the season, and the closer together the plants are the more likely are they to draw up and fail to form solid sprouts. At this time the error is generally seen, and to guard against destruction from damp, those in charge resort to lopping off the side leaves, so as to obviate the evil as much as possible, or else they soon become a decaying mass. With free exposure to the sun and air the stems, instead of drawing up to an inordinate length, grow steadily and well, and the side leaves, instead of dying away, form a natural covering to the side sprouts.

Planting Winter Kales, Broccoli, Savoys, or any of the dwarfier-growing winter greens between rows of Potatoes is a system to guard against if possible, as the plants when first set out are overshadowed by the Potato haulm; consequently they draw up weakly and are devoid of that stamina which is so essential to enable them to pass through a severe winter, and are also not nearly so productive as they should be. The rows of Celery are often arranged far too closely together, and here we may resort to double cropping with advantage, so as to economise the room where the rows are set out from 5 feet to 6 feet apart. Lettuces never thrive better than when planted along the ridges, and as the autumn draws near the plants are effectually guarded against destruction from damp. Not only Lettuce, but such vegetables as French Beans, Turnips, or any dwarf quick-growing crop, may be planted with advantage, so that these may be off by the time the soil is required for earthing. The want of sufficient soil for earthing is often the cause of the destruction of Celery by frost. Turnips, again, also suffer from the evil of close cropping, especially in the case of those for winter use or storing. Not only are the rows arranged far too closely together, but the seed is sown much too thickly, and, besides the loss of time entailed through the process of thinning, the bulbs do not form as they should do. It must also be understood that the varieties which make their growth during the late summer and autumn months form much larger tops than those of summer growth, so the rows must be arranged accordingly. Each plant, as it were, must have sufficient space allowed in the operation of thinning to have room for developing both the bottom and top growth.

Among the various crops grown for winter and early spring use Parsley is one of the most prominent, but yet in many gardens it is ill-provided for, and there are more failures through the error of allowing the growth to become crowded during the earlier stages of growth than from any other cause. Allowing each plant room for free development, so that the growth may be enabled to become well matured, goes a long way towards ensuring satisfactory results.

Coleworts.—Make good any failures that may have occurred in former plantings, and continue to make fresh plantations, for, although Coleworts are not particularly hardy, they will, if the autumn is favourably, come in useful before there are any severe frosts.

GARDEN FOOD.

TOMATO COOKERY.

THE Italians make much use of the Tomato with their meat dishes, but we have to deal mainly with garden food here:—

MUSHROOMS WITH TOMATOES.—As the Mushroom season is upon us some use of them with Tomatoes may be tried as a change. Put a pint of Tomatoes in a saucepan and cook for fifteen minutes until all the water has evaporated. Season lightly, add a tablespoonful of butter, a tablespoonful of breadcrumbs, and a half pint of young Mushrooms chopped fine. Cook until the Mushrooms are tender. Have some bread, cut in nice slices, toasted. Pour the Tomatoes and Mushrooms over, and serve very hot.

SAUTE TOMATOES.—Wipe 1 lb. small, firm, even-sized Tomatoes with a cloth, and cut into slices. Peel and chop two Shallots finely. Melt $\frac{1}{2}$ oz. butter in a sauté pan; when hot put in the Shallots and fry to a golden brown. Be careful not to let them get too brown, else the flavour of the Tomatoes will be spoilt. Place in the Tomatoes, and cook lightly over a brisk fire—they will take about ten minutes to cook.

SWEET CORN AND TOMATOES.—Boil dried or fresh Corn until perfectly tender, add to each cup of Corn two cupfuls of stewed, strained Tomatoes, either canned or freshly cooked. Salt to taste, boil together for five or ten minutes, and serve plain or with a little cream added. Sweet Corn is now in use, and this makes a good dish.

TOMATO PILLAU.—Slice one or two small Onions, and fry them in a stewpan to a golden-brown in 2 oz. of butter. Add 1 pint of Tomato purée and $\frac{1}{2}$ pint of vegetable stock. Season with salt and pepper, and bring to the boil. Skim, and add $\frac{1}{2}$ lb. of well-washed rice, and cook gently until the liquor is almost absorbed. Melt 2 oz. of fresh butter in a stew-pan, when hot add the rice, and stir over the fire for a few minutes. Cover the pan, and place it on the stove for about 15 minutes.

BROILED TOMATOES are delicious at the morning hour. Cut solid ripe Tomatoes into slices, season and dust them with crumbs, and broil over a quick fire. Serve on a hot platter, with cream sauce, the slices laid on toast, if desired.

PANNED TOMATOES.—Cut large Tomatoes into halves, put them into a baking-pan in a cool oven for a half-hour, and, when done, lift carefully without breaking on to a meat platter. Add a half-pint of milk to the pan, then one tablespoonful of flour mixed to a paste. When boiled, season and pour over the Tomatoes. When you put the Tomatoes into the pan, put a little butter in the centre of each and season well.

BAKED TOMATOES.—Cut out the centres of six large Tomatoes. Mix with the pulp one cup of breadcrumbs, a little Onion and green pepper cut very fine, one tablespoonful of butter, salt and pepper. Stuff the shells with the mixture, put a little butter on top of each and bake for one hour in a pan set in a pan of water.

TOMATOES AND MACARONI.—Scoop out the centres of large, fine Tomatoes, and stuff with the following filling:—Three ounces of macaroni broken into small pieces, boiled until tender in salted water. Drain and mix with one cup of cream sauce, two tablespoonfuls of grated cheese, salt, and paprika. Fill the Tomatoes and cover with butter and breadcrumbs. Bake until tender.

BOILED TOMATOES.—Choose small, firm Tomatoes and rather under than over ripe. Wipe them and remove the stalks without damaging the skin in any way. Put them into a saucepan of boiling water slightly salted and let them boil slowly from 5 to 7 minutes. Then lift them out with a draining-spoon, or a frying basket may be used for putting the Tomatoes into and lifting them out of the water. After draining, place them in a hot vegetable-

dish and serve at once. A little plain or *maitre d'hôtel* butter should be handed separately, the Tomatoes being eaten from the skins, like boiled egg, with a little butter, pepper, and salt put inside.

TOMATOES AU GRATIN.—Three or four Tomatoes, three tablespoonfuls breadcrumbs, two tablespoonfuls grated cheese, 1 oz. butter. Salt, pepper. Put the Tomatoes into a basin, cover them with boiling water and let them stand a minute or two. Then lift them out, dry them, and remove the skins. Cut them in slices, keeping them on a plate, so as not to lose any of the juice, and season well with pepper and salt. Mix the breadcrumbs and grated cheese together and grease a small pie-dish or fireproof dish. Put first a layer of the Tomatoes at the foot of the dish, then some of the breadcrumbs and cheese, more Tomatoes and so on, arranging them in layers until all are used up. The last layer should be the breadcrumbs and cheese. Lay the butter in small pieces on the top and bake in a moderate oven.

STEWED TOMATOES.— $\frac{1}{2}$ lb. Tomatoes, sugar, 1 oz. butter. Salt, pepper. Wipe the Tomatoes and remove the stalks. Place them for a minute in a basin of boiling water, then lift them out and peel them carefully with a sharp knife, commencing at the stalk end. Now cut the Tomatoes in slices or quarters, removing the hard pieces from the inside, and put them into an enamelled or earthenware saucepan. Season lightly, put the lid on the pan and stew slowly until tender. Add the butter and serve in a hot dish. A little finely chopped Onion or Shallot may be added if wished. Time to stew, 15 to 20 minutes. Sufficient for two or three persons.

TOMATOES WITH CURRIED RICE.—Six Tomatoes, salad oil, seasoning, 3 oz. Rice, some light stock, one teaspoonful curry powder, two or three tablespoonfuls brown gravy. Choose large, firm Tomatoes, wipe them, remove the stalks and cut them in half transversely. Squeeze out the seeds and watery part from the centre, and arrange the pieces on a greased fireproof dish. Season them with pepper and salt, sprinkle with a little salad oil, and cook in a moderate oven about ten minutes. Wash the Rice and cook it in light stock until tender and without making it too moist. Season with the curry powder and a little salt if necessary. Fill the Tomatoes with the curried Rice, sprinkle them with some good brown gravy, pouring the remainder round, and return the dish to the oven for a few minutes. Serve the Tomatoes on the dish on which they have been cooked. Sufficient for five or six persons.

TOMATOES A LA FRANCAISE.—Six small ripe Tomatoes, one cupful white or béchamel sauce, a few browned bread or biscuit crumbs, a little butter. Wipe the Tomatoes, remove the stalks, and peel them. Grease half dozen small china or earthenware dishes and put a little sauce at the bottom of each. Place a Tomato on the top with more sauce over and sprinkle a few crumbs on the top. Lay a small piece of butter on the top of each and bake in a moderate oven until the Tomatoes feel tender when tested with a skewer. Serve the Tomatoes in the dishes in which they are cooked as a separate course at dinner, or as a supper or luncheon dish. Time to cook, 10 to 15 minutes. Sufficient for five or six persons.

TOMATOES A LA PORTUGAISE.—Six Tomatoes, 1 oz. butter, one tablespoonful chopped Onion, seasoning, 3 oz. Rice, one cupful light stock, two tablespoonfuls grated cheese. First prepare the Rice mixture for filling the Tomatoes. Wash the Rice and dry it well. Melt the butter in a saucepan, put in the chopped Onion and fry it until lightly browned. Add the Rice and cook it a few minutes without allowing it to take colour. Then pour in the stock, season to taste, and cook until the Rice is tender and the stock absorbed. Wipe the Tomatoes, cut a slice off the stalk end of each and scoop out the soft inside. Fill up with the rich mixture, piling it high in the centre. Sprinkle with grated cheese, put a small piece of butter on the top of each Tomato and cook in a moderate oven from 12 to 15 minutes. Serve hot, garnished with Parsley. Sufficient for five or six persons.—*Jack's Cookery.*

OUTDOOR PLANTS.

MISTAKES AS TO MIXED BORDERS.

A MIXED border may be, and often is, the ugliest thing in a country garden, and may also be a beautiful feature. The things to avoid are as follows:—(1) Silly repetitions, a very common fault and easy to avoid. It often concerns some favourite plant and it is repeated along the border with the view of impressing its charms on the beholder, the plan destroying all the beauty of the border. The best result is often got from a single group of a fine plant. I would not repeat at all if satisfied with a group, as there are so many things worth a place both for foliage as well as flower.

(2) CURIOSITIES, BOTANICAL, AND UNTRIED PLANTS.—In the good mixed borders

a botanical garden that is another affair. It is descriptions in books and lists we have to think of, and usually to avoid.

SOIL, ASPECT, AND BACKGROUNDS.—Thin, very dry soils are best avoided or well improved so as to avoid failures in dry years. A depth of 3 feet of good soil is the best. Borders running north and south on sloping ground are not so good as east and west. Backgrounds are a great gain—the best an old stone wall. Where borders run through a kitchen garden it is best to have a bold trellis of Oak, where Oak is plentiful, to separate the border from the crops. This, covered with Roses and Clematises, gives a lovely background, and a place for climbers which may not come well in the mixed border. Where Oak is not at hand an iron trellis will do, but it should be painted stone colour and covered in most

should be on its own roots, i.e., not grafted in the usual trade way.

BORDERS OF ONE COLOUR OR OF ONE SEASON.—These, which appeal to some, and may be well done, are not such as come under well-made mixed borders. There is no sufficient choice in them and no room for the variety and contrast that should be seen in a good border, which should attract for all summer and well into autumn.

CHOICE OF PLANTS.—That is the most important thing of all, and a very high standard should be sought. We have often dealt with such a choice in these pages in the past, so there is no need to elaborate it here, though we may repeat it.

GAPS.—These often occur through failures, changes of taste and new ideas, and want of time to replant during winter

The flower border at Penhros.

a high standard of quality is essential, therefore it is better to omit these. No plant should go into it that the planter does not know and like. Both from the botanical and trade sides danger must be looked for! Novelty is best in a nursery-bed apart until fairly tried. This is important and may save from mistakes. The relation of botany to gardening is well to think of, as the two things are quite apart—botany a world science and gardening an art that must arise out of the ground in any given country. To the botanist all plants are of equal value, and rightly so. To the gardener their beauty and fitness for his climate and soil are the first things to think of. Therefore, plants coming from botanical sources should be tried in the nursery before getting a place in the choice border. If we have the gain of seeing a good plant in

visible parts with Oak or other battens or strips of Rattan or Reed.

SHORT BLOOMERS.—Some of these are handsome, but better kept with other plants to relieve them, as, say, the Giant Asphodels (*Eremurus*), which, imposing as they are, soon give over and leave blanks. Many plants used have too short a season of bloom, some Lilies among them. Roses that bloom a long time, like the Tea and China Roses, may often be used with good effect in the mixed border, and both the Clematises and Roses on the trellis should be kinds that flower long or give a second bloom. Late bloomers like *Solanum jasmuoides* should have a place on the trellis, while room should always be found for a plant of the fine red Rose Cramoisie, the climbing form, which, like all the China Roses,

and early spring. These should be made up with good plants only—*Heliotrope*, Carnations out of pots, tall red *Lobelias*, blue *Salvias*, and the finest *Verbenas*.

W. R.

***Achillea Wilczekii*.**—This is one of the stronger growing of the silvery hybrid Millfoils. The leaves, each 3 inches to 4 inches in length, spatulate in outline, and with deeply-gashed margins, are greyish-green rather than of the conspicuous silvery hue characterising such as *A. Clavennæ* for example. At the same time it is one of the most distinct of a rather numerous race, its silvery or grey colour dependent doubtless to some extent upon exposure and influenced considerably by soils. The large-spreading corymbs of white flowers are very effective, and not a little suggestive of the in-

fluence of the coarser growing *A. lingulata* buglossis, modified it may be, and whitened by reason of opposing influences from the other parent. Withal it is a good plant, one whose finer attributes are likely to be forthcoming in poorish soils or rocky ground.—E. H. JENKINS.

HARDY FLOWER NOTES.

DRABA BRUNLEFOLIA.—Very neat and compact of habit, this species is not difficult of culture, increases with tolerable freedom, and blooms freely where the conditions are to its liking, but if this is not the case it is liable to a sudden collapse, the plants turning brown and eventually dying off. When examined it will be found that there has been a failure more or less complete of root action, and this is, in nine cases out of ten, brought on by an unsuitable rooting medium. This *Draba* does not make any quantity of roots, and these are fine and very sensitive to excess of moisture. At the same time it is apt to turn brown in a time of severe drought if planted in very light soil deficient of organic matter. Pounded brick and mortar rubble, with a little loam in which the roots can remain in a healthy condition during the winter and which does not allow of the free admission of a parching air in the growing time, is best calculated to ensure permanent vigour in this little alpine.

CAMPANULA GRANDIS.—A fine, easily-grown species, with 3 feet spikes of bloom when the season is fairly favourable, and doing well in very light soils that quickly lose their moisture. The white variety has never been so vigorous with me, but it is very reliable. This is a true mixed border *Campanula*, as it is capable of holding its own when in intimate association with other straggling perennials.

THYMUS AZORICUS.—I am growing this for the first time, and cannot say much in its favour. As a carpet plant it has merits, but the flowers are inferior to those of the common Thyme, which is much superior. What it may be as a wall plant I cannot say; the colour of the flowers may be better.

ASPERULA GUSSONI.—A pretty little member of the Woodruff family this, and well worth a place in the rock garden if only on account of its very neat, compact habit and fresh verdure, which is of a very enduring nature. The flowers are, however, pretty and produced abundantly. It grows freely in ordinary fairly light soil and is one of those things that the beginner in the culture of alpine plants can safely take in hand.

OURISIA COCCINEA.—The first plant of this I had flourished exceedingly, and in the course of a couple of seasons covered a piece of ground quite 1 foot square. No plant could have done better. There was a demand for it, and a number of well-rooted pieces were taken off, allowing enough to remain to fill up the gaps. To my surprise and grief, however, by the end of the season only a few miserable shoots were left. For some time I left it alone, and then thought I would give it another trial. I procured a couple of nice, healthy plants; one was placed in a sunny position, the other was put on the north side of a low wall. The former dwindled, the latter grew and bloomed well. I took several well-rooted pieces from it, and from that time it never flourished, and the young plants died. It is evident, however, that it cannot behave in this way everywhere. There must be places where it can be lifted and where propagation can be effected without injury, otherwise it would in time disappear from cultivation. There are some hardy plants that in some

places give no trouble to the grower, increase very freely, and can be transplanted and divided at will, but in others it is a matter of chance if they thrive and take on permanent vigour. This *Ourisia* is evidently one of them. I would advise all who may have a nice, healthy specimen to be very careful and neither lift, divide, nor in any way mutilate unless they are well assured that they can do so with impunity. In the case of things of such an uncertain nature it is well to start with two plants, one to remain undisturbed, the other to be divided or propagated from in some way.

SAXIFRAGA OPPOSITIFOLIA.—Can any of your readers say what the conditions are that induce the maximum of free flowering in this species? It is easy enough to grow, but in a general way cannot be depended on to bloom with even a fair amount of freedom. The best specimen I ever saw was at Wisley. It was very fine and large, and sometimes bloomed. I have been told that it flowers much more freely in Scotland than in the southern parts of England. If so, it must be a question of atmosphere and moisture at the roots. The dry spells we are apt to get in the south probably affect the formation of flower-buds, which, in the case of such an early-flowering species, must be dependent on the condition of the little creeping growths at the close of the autumn. I have never managed to get more than a dozen flowers on a fair-sized plant, and have been content to obtain that number, but it has not infrequently happened that a solitary blossom has been the reward for a season's careful culture. It is an interesting species and very attractive in bloom so early in the season. The pity is that it cannot be induced to flower with greater certainty and freedom.

J. CORNHILL.

OURISIA COCCINEA.

I WROTE of this plant recently, in the hope that a considerable practical experience of it in diverse localities might be helpful to some of those who had despaired of making it a success. I gave, indeed, one notable instance where the plant had puzzled a good gardener and where failure had been reversed. Pointing out some of its peculiarities, I referred to the need for ensuring "a perennial continuity of growth," and, knowing full well that this does not occur in all soils alike, I wrote "to this end occasional division and replanting are necessary." I believe it was Mr. Arnott who remarked recently that the plant was "the despair of many gardeners," hence it is odd that he should find fault with my trying to put an end to some of that despair. The fact that it does well in some districts and less well in others is known to many, while the inferior results secured in some could be often enough turned into complete success if gardeners would but give the plant the special care it needs. In one instance I recall, where the nursery stock plants to the extent of some 300 were planted out in poor soil only watered from above, hardly any of them made sufficient growth to produce a flower, yet the pot-grown examples in plunging beds taken from a part of them, cultivated in prepared soil, and receiving daily attention in watering and other ways, flowered as well as could be desired. It is object-lessons of this sort, coming as they do within the region of personal observation for months on end, which give backbone to experience, and carry far greater weight than the knowledge gained by casual visits to gardens, be they ever so good or well tended. Mr. Arnott says he knows gardens where the *Ourisia* "flowers well

annually, and where it is never lifted." How many years this has been so is not stated, but a plant of its nature and mode of growth cannot go on indefinitely, and may already, as often happens in the case of three-year-old planted clumps, be only flowering on the outskirts of the group. That, however, is not success in the measure it should be gauged in a garden where the plant succeeds at all, though it may be made so by the "occasional division and replanting" I have recommended, and which, rightly done, tend to the fullest development of existing rhizomes, while affording opportunity for the formation of new. This, in the case of a mat-forming, rhizome-making subject like the *Ourisia*, is essential to complete success, and the sooner gardeners realise it and act up to it the earlier will they reap the brilliant harvest the plant is capable of giving.

Nor am I in the least sympathy with the suggested idea that the plant can only be grown in one spot in some gardens. Indeed, it is inconceivable. I am not denying that the repeated failures to which Mr. Arnott refers have actually occurred. I fully believe they have, knowing of like instances. Traced to the source of their origin, however, they are usually found to be due either to planting clumps of too solid a nature, which rarely make a good start, to indifferent planting, to lack of soil preparation, or subsequent inattention. The first is a fundamental error. Best of all ways of establishing fresh colonies is to lift a clump or portion of it, wash away all soil in water, detach the youthful-growing rhizomes with roots, and pot them two or three together—singly where a small stock obtains—in 3-inch pots in well-prepared soil, placing them in a close frame to recover. This may be done in August or September, or in March. If the former, the permanent planting would be better deferred till spring, though in some districts the newly-established plants may be put out as soon as ready. Quite naturally this involves a little extra trouble, though the success it ensures is well repaid.

E. H. JENKINS.

A BRIGHT CORNER.

ONE can understand the difficulty experienced in growing and flowering successfully such things as *Gentiana acaulis*, *Alstromerias*, and the *Ourisia* named in a recent issue, but it is not so easy to account for failure with a plant like the double Sneezewort (*Achillea ptarmica* fl.-pl.). In the majority of places it is impossible to include it in borders devoted to high-class hardy plants, as in two or three seasons, if left to itself, it will monopolise four or five times the space allotted to it and is a perfect rambler. It is, however, a beautiful flower, associating well with many that may be termed rough, hardy flowers and reminding me of its value in a corner of my garden, where it is at home with the old *Anchusa*, equally difficult of eradication, the two making a very pleasing contrast, together with batches of the annual Cornflower in blue and white, or, rather, light grey. In the background are many clumps of the lilae and white forms of the Goat's Rue, *Galega officinalis*, also a most accommodating and enduring plant, and one that can be kept in flower for a long time if cut back a bit when the early blooms are decaying, and occasional soakings of water given. In common with many hardy plants endurance is prominent in the Goat's Rue, for if planted at first in a soil that is good and holding, it will grow and flower satisfactorily undisturbed for many years. With the Goat's Rue are associated clumps of Everlasting Peas raised from seed, and consequently showing, so far as

the rose-coloured sorts are concerned, several different shades. These are growing on some live Willow stakes. I cut some fairly stout, straight bits about 8 feet long from a tree that was overhanging the garden, trimmed them a little and stuck them in by the Peas. They nearly all lived, and since the Peas commenced to flower the effect in association with the little Willow twigs is very pleasing. Also in the background there are clumps of *Artemisia lactiflora* and *Aster Mrs. C. H. Rayner*, which attain about the same height. The foliage of this *Aster* seems to be more strongly scented than that of any of the family, quite a strong perfume being emitted when one rubs against it.

There were a few vacant places in the central and back parts of the corner affording the opportunity of putting an occasional plant of Dahlias like *Souvenir de Gustave Douzon* (scarlet) *Jeanne Charmet*

NOTES AND REPLIES.

Increasing bedding Lobelia.—A good hint was recently given in GARDENING ILLUSTRATED by, if I remember rightly, Mr. J. Cornhill, about the sowing of seeds of the above at this season instead of early in the year, as is the custom. I should like to mention that now is a good time to set about increasing the named sorts by means of cuttings. For some years I had to raise large quantities—30,000 or 40,000, and, finding some difficulty in obtaining cuttings by the old method of lifting plants in autumn, I hit upon the plan of rooting a batch in August or September. By planting a batch out in reserve, cutting them hard back in early August or thereabouts, earthing up with fine, sandy soil, and giving frequent sprinklings of water in the absence of rain, a new and vigorous growth was secured which, rooting afresh into the new

sight. It grows rapidly in any good loam, but wants plenty of room, as a well-grown bush will often be 40 feet or 50 feet in circumference. It is easily propagated by layering.

Gazania splendens.—The rich orange colour and the contrasting dark centre of the flower combine to make a very effective display in borders which are naturally rather dry. It should be propagated early, as the best results—earlier and freer flowering the following year—follow. I have tried plants this year on a rockery, and they have done well. Old specimens wintered in sand may be started in March and finally planted round the sides of outdoor vases with good effect. The *Gazania* forms a splendid carpet to half or standard *Fuchsias*. The closing of the blooms at night and during dull, rainy weather is a drawback.—BOURNE VALE.

Antirrhinums.—These are now in full beauty. To prolong the flowering period the seed pods must be picked off as fast as they

Mixed border, Gravetye; July. (See page 439.)

(pink), and *Yellow Colosse*. These are too large to suit some tastes, but they make a fine show and there is no mistaking the size and symmetry of the flowers; in fact, there is nothing quite like them of their height in the garden. There were some nice clumps of *Antirrhinum* in different shades, but these disappeared suddenly and somewhat mysteriously last winter, and their places have had to be filled for the summer with *Cornflower* and *Clarkia*. In the *Clarkias* the colours in some of the later introductions are exceptionally brilliant. A bit of occasional foliage is supplied by some small bushes of *Choisya ternata*, which, the situation being very sheltered, are doing remarkably well. This was not included in the list of scented shrubs recently published in GARDENING ILLUSTRATED, but I should put it among the very best, quite in the first half-dozen.

Hardwick.

E. B. S.

soil, afforded an unlimited supply of the best type of plant at a minimum of cost and labour. All I did was to lift the tufts when ready, pull them into small pieces, and replant in shallow propagating trays in sandy soil. Placed in a close frame and watered they gave no trouble whatever. Two months later the boxes were a perfect sward of growth, with vigorous cuttings available by the thousand. The method is applicable to other plants—*Ageratum*, *Alternanthera*, etc.—and, as a great time-saver, is worthy of consideration.—E. H. JENKINS.

Spiraea Lindleyana.—This has been very fine this year as a specimen bush on the Grass. It grows from 8 feet to 10 feet high, or even more, its finely-cut, Fern-like foliage being always handsome, even when out of flower. At the end of July, when covered with its large plumes of cream-coloured blossom, it is a beautiful

form and the roots kept supplied with water. After the first flush of bloom is past a successional crop of spikes will quickly appear if the plants are given a look over, cutting the old ones down as low as possible and picking off dead leaves, etc. Those who have not the conveniences for raising a number of plants in spring should do so now either by sowing seed or propagating them from cuttings, the latter being the better method if necessary to keep the different varieties quite distinct and true to colour. If a large number is required, the best way is to prick the cuttings out into a frame in the same way that *Calceolarias* are treated.—A. W.

Stokesia cyanea laevis.—This is a much larger-flowering form than the type, and, coming into blossom early in August, is valuable on that account. The light blue colour, too, is paler than in either the old typical kind or that occasionally met with as *S. c. praecox*, though it approximates to the latter. It is now in flower in the herbaceous ground at Kew.—E. J.

INDOOR PLANTS.

THE SCARBOROUGH LILY
(*VALLOTA PURPUREA*).

OF greenhouse bulbs that flower during the late summer and early autumn months this is one of the most showy, and given healthy, well-established bulbs to start with it can be kept in good health for an indefinite period. Given a good loamy soil, lightened if necessary by a little leaf-mould or peat and a liberal admixture of sand, the *Vallota* will stand for years without repotting and flower well each season. A mistake is by some made of keeping the bulbs quite dry during the winter in order, as is supposed, to give them a rest, but this is quite contrary to their nature, as they grow, though slowly, at that season, the nearest approach to absolute rest being in the early summer, and at no time do they go totally dormant as many bulbs do. Within the last few years considerable numbers of bulbs have been sent to this country from their South African home, but though on arrival they appear very promising, many of them prove to be a disappointment. They are very difficult to establish in a satisfactory manner, as, however dry they may be kept, many of them often perish from an excess of internal moisture, while a kind of mite is frequently troublesome. There is a considerable amount of variation to be found in the flowers of these imported bulbs, but as far as my experience goes the fine round flower with broad, well filled in segments is by no means plentiful. Imported bulbs, if potted on receipt, should only be kept slightly moist in order to encourage gentle root action, and they should be placed in a light, airy position in the greenhouse. These freshly imported bulbs take some time to adapt themselves to the change of seasons, hence the first year they often push up flowers in the spring, and at once attract attention by reason of their novelty. Flowers more or less of a pinkish tinge often crop up among these newcomers, but after being grown for a year or two in this country they (in many cases, at least) assume the normal tint.

NOTES AND REPLIES.

Treatment of Plumbago.—I should be grateful for advice regarding the treatment of a Plumbago in my greenhouse. It is ten or twelve years old, and has grown large and strong, covering a brick wall about 9 feet high. In former years it bloomed freely from top to bottom. It then suddenly stopped flowering for some unknown reason. Three years ago it had only four or five flowers; none at all the last two years. This year it shows three or four buds. It looks perfectly healthy, with fine foliage. It is cut back severely every year, as formerly, in the autumn. The growth is so strong and vigorous that no manure has been applied to it. I can only suppose that the pruning is at fault, but, so far as I am aware, no change has been made in this respect. Any advice as to the best way of restoring the flower production would be welcomed.—SUBSCRIBER.

[Your question is a difficult one to answer, and we are inclined to think that the roots of the Plumbago have too much run; perhaps they have found their way into a drain. This opinion is borne out by the strong growth the plant makes. A curtailment of the roots, which would tend to check the vigorous growth, would probably induce it to flower freely. Again, hard pruning tends to the production of gross shoots rather than flowers, so very probably you would have a better display if another season the plant were pruned but lightly.]

Tacsonia insignis.—One frequently meets with *Tacsonia exoniensis* and *T. Van Volxemi*, yet this species is rarely

seen. This to a great extent can be accounted for by the fact that it is more particular in its requirements than the two previously mentioned. It is a native of the Andean region of South America, and like many plants from that district is seen at its best in a fairly moist atmosphere. Being necessary to grow it under glass, these conditions cannot always be ensured it, and then the foliage is particularly liable to be attacked by red-spider, which, if unchecked, will ultimately kill the plant. A notable feature of this *Tacsonia* is that the leaves are simple, or nearly so, whereas in the other members of the genus they are lobed. The leaves of *T. insignis* are about 6 inches long, dark green above, and in common with the young shoots are clothed on the undersides with a rusty-coloured tomentum. It is this which affords such shelter to the red-spider. The flowers are large, pendulous, and of a rich violet-crimson colour. The cultural requirements of this *Tacsonia*, apart from a fairly moist atmosphere, are good head room, as it will not flower well if cramped either at the roots or tops. A liberal use of the syringe is also essential, as in this way troublesome pests are kept in check.—K. R. W.

Pandanus Veitchi.—This is useful in many ways, and I would not willingly be without it. It is useful alike for the table or for vases, being light in appearance, with its recurving foliage almost hiding the pot in which it is grown. To preserve the variegation, *P. Veitchi* must be rather restricted in respect of root-run, but sparingly plied with stimulants. If overdone in either respect, the leaves are apt to turn almost green, with the white barely showing through. Young plants are always best, and such are easily obtained by propagating the suckers which the plant freely produces. Select the smallest pieces, for it will be noticed variegation is more pronounced in these than in the larger suckers.—Kirk.

Saintpaulia ionantha.—This really requires a stove temperature, but it may be grown with a fair measure of success in a warm greenhouse. Its blue Violet-like blooms are always welcome. Being of a dwarf habit it is very useful as an edging. It can be quite easily increased from leaf cuttings, which, if put into Cocoa-fibre in a close propagating pit at any season of the year, soon root and form neat plants. Quite good pieces can be grown in 3-inch pots, and it is not advisable to allow any more root-run than can be provided by, at the outside, 4-inch pots.—Scor.

Liliums for furnishing the show or flowering-house in mid-August and early September require staking and tying. The pots being filled with roots, liquid-manure and an occasional dose of Clay's fertiliser will now be afforded. If fly becomes troublesome, the best way of coping with the attack is to take the plants into a house and vaporise them. If taken in time, these measures are usually sufficient to destroy them. When the attack is a bad one or is allowed to become so before steps are taken to deal with it, then nothing short of dipping the point growths in an insecticide will be of any avail.

Primula sinensis.—Young plants require a slightly warmer and drier atmosphere than *Cinerarias*. The earliest plants are now ready for potting into 5-inch pots, using a compost of one-third each of loam, leaf-soil, and peat, adding sufficient coarse sand and broken charcoal to render it porous. After potting, they are placed in a frame near the glass and given a shading of tiffany on all bright days. Watering needs careful attention, and must not at any time be given in excess. Ventilation also requires close attention to keep the plants sturdy and compact, for if kept too close they quickly become drawn.

Under glass.—During the week the work under glass was reduced to the barest minimum which was consistent with the well-being of the occupants of the houses. Watering was done early in the morning, and the necessary ventilation attended to

THE WEEK'S WORK.

OPEN-AIR GARDENING.

IN BLOOM AUGUST 23RD.—*Yuccas*, *Kniphophias* (in variety), *Phloxes* (in variety), *Hollyhocks*, *Helichrysums*, *Romneyas*, *Lavateras*, *Acanthus*, *Anemone japonica* (in variety), *Anchusas*, *Enocheras* (in variety), *Sidalceas* (in variety), *Galeogs*, *Echinops*, *Eryngiums*, *Erigerons*, *Thalictrums*, *Helenium pumilum*, *Chrysanthemum maximum* (in variety), *Aster Amellus*, *A. cordifolius*, *Rudbeckias*, *Montbretias* (in variety), *Agopanthus*, *Achilleas* (in variety), *Geums* (in variety), *Cimicifuga racemosa*, *Heucheras* (in variety), *Delphiniums*, *Funkias*, *Verbasiums*, *Hyacinthus candicans*, *Gladiolus* (in variety), *Plumbago Larpentæ*, *Lysimachias*, *Solidagos*, *Epilobiums*, *Hemerocallis* (in variety), *Lythrum roseum*, *Senecio Clivorum*, *S. THE WEEK'S WORK.—During the week heavy and welcome rains have fallen, and everything will greatly benefit after such a long dry spell. Constant attention is necessary during stormy weather to see that all stakes and ties are secure. Perennial Asters (*Michaelmas Daisies*) particularly require attention in this direction. These are now growing strongly, and if the weather is favourable there will be a magnificent display of bloom in September. These are seen to the best advantage when grown in a border by themselves. They are also very suitable for planting in bold groups on the margins of shrubberies, and are indispensable in the mixed border. *Lilium tigrinum Fortunei* is now making a grand display. This is a most satisfactory variety, and is worthy of extended cultivation. It is very hardy, and thrives almost anywhere and in any ordinary soil. *Lilium auratum* and *L. speciosum* are also flowering freely, but as these varieties do not stand the winter well in this locality the bulbs are lifted as soon as the foliage dies down, potted up into pots of a suitable size, and stood in cold frames for the winter, planting them in their permanent quarters in early spring. A batch of *Rose* cuttings has been put in. The cuttings are selected from firm, well-ripened shoots that have just finished flowering, selecting pieces 6 inches to 8 inches long, and taking them off with a heel, which is carefully trimmed with a sharp

knife, the lower leaves and a little of the soft tip being removed. A piece of ground under a north wall was prepared, adding plenty of coarse sand and a little leaf-mould. The soil was trodden firmly, a frame placed over it, and the cuttings dibbled in to half their length, making them quite firm, afterwards giving a good watering. More seeds of various hardy plants have been sown during the week and others have been gathered and will be sown shortly. F. W. GALLOP.

Lilford Hall, Oundle, Northants.

SOUTHERN COUNTIES.

Early-flowering Chrysanthemums.—Never have these made better growth than they have done this season, and in due course there will be a fine display of bloom. As the growths are so liable to be damaged by high winds, the plants should be now looked over and staked where necessary. The roots will now demand abundant supplies of water, supplemented by liquid-manure when it can be spared. When the latter is scarce, artificial manure sprinkled on the surface and hoed in is very helpful.

Michaelmas Daisies.—In hot weather the hoe needs to be frequently plied between the plants and the roots of the latter kept well watered, otherwise mildew will speedily attack the foliage, with the result that the floral display later on will at the best be unsatisfactory. Frequent inspection of the growths is necessary, as they quickly fall about if left unsupported should a wind spring up. Staking and tying of these plants require to be done with great judgment if the beautiful effect produced by them when in bloom is not to be marred.

Pelargoniums.—The latest-flowering batch should now be stood outdoors in full sunshine so that the wood may become well ripened before it is cut back to ensure new growths with which to lay the foundation of new heads for another season. Watering at the roots must be sparingly done, and in the event of a heavy rainfall lay the pots over on their sides for the time being. The earliest lot of plants should now be shaken out and repotted, after trimming off some of the oldest roots, into pots one or two sizes less in diameter than those they previously occupied. A pit will be the best place for them for a time, and until they recover from the shaking out shade from hot sun.

Zonal Pelargoniums.—All flowers must be suppressed and the roots well fed in order that the growth now being made shall be robust and in due course produce an abundance of bloom. To prevent the roots pushing through the crock boles and becoming attached to the ashes on which they stand the pots should be moved round at least once a week.

Cyclamens.—Warmer conditions will now allow of the more free ventilation of these than was possible earlier in the season, consequently, current growth is more sturdy and robust-looking than would have been the case had the dull, cool weather continued. Treatment now necessary is to well shade, to ventilate freely, to gently dew the plants overhead three or four times during the day, to keep the ashes on the bed constantly moist, and to fume or vaporise occasionally more by way of prevention than otherwise, as thrips must not be allowed to gain a footing. The time is close at hand when seed should be sown to supply plants for blooming in the latter end of next and the spring of the following year. The necessary quantity of seed in different varieties should accordingly be purchased in readiness.

Seakale.—The plants will now need every assistance if fine crowns are desired. Good stimulants are salt, nitrate of soda, sulphate of ammonia, and guano. Whichever is preferred or found most suitable for the class of soil to be treated should be sprinkled between the rows and lightly hoed in. The old plants in permanent plantations are sending up many heads of flower this season. These should be removed as soon as detected. Surplus liquid-manure may be poured between the rows of these established plants with advantage.

Mushrooms.—The material for the making of the first bed should now be in the right condition for doing so, and the earlier this is carried out so much the sooner will Mushrooms be available. Whether the bed is to be made on the flat or ridge-shaped, the manure must, if success is looked for, be spread evenly and thoroughly consolidated both by beating and treading it as the bed is formed. When finished insert either a trial stick or bottom-heat thermometer, the latter being the more reliable, and when the heat has declined to 85 degs. the bed may be spawned and soiled over. The temperature will then recede, but so long as it does not fall below 65 degs., no covering is needed at this time of year. If covering does become necessary, this may take the form of hay, short litter, or mats.

Tripoli Onions.—The seed should, if such has not already been done, be sown at once, well soaking the drills with water before doing so, unless rain should in the meantime fall in sufficient quantity to well moisten the soil. Sowing on dry and loose ground invariably ends in failure, for which the blame is often attributed to the seed not being good.

Parsley.—The plants which are intended for the winter and spring supply should be well thinned in the lines. The thinnings, if carefully taken up, come in useful for filling boxes, pots, or pricking off into a roughly constructed cold pit for use in the winter when the ground is covered with snow or hard frost prevails.

Cauliflower seed.—That recently sown requires to be well looked after in dry weather, otherwise there is a risk of the young plants, just coming through, perishing. Water must be freely applied and the young plants occasionally dusted over with wood ashes.

New Zealand Spinach.—In hot, dry weather, particularly when the rainfall is deficient, the value of the foregoing is very apparent. The plants revel in such heat as is now being experienced, and if occasionally soaked at the roots with water yield an extraordinary quantity of leaves. Unlike other kinds of Spinach, this does not run to seed.

Late Melons.—After this date it is only in well heated structures that any degree of success may be looked for in Melon growing. Where a late crop is desired the plants should now be set out, using boxes or large pots for the purpose in preference to planting them on hillocks or narrow borders of compost made up on the fermenting material or the slates or slabs covering the chamber in which are situated the pipes for supplying bottom heat.

Ripening Melons.—Ideal conditions now prevail for the finishing of Melons which have reached the ripening stage, and with an abundance of sunshine and some small amount of bottom heat high quality may reasonably be expected. The warm outer air can now be admitted freely in the daytime and in a less degree at night. Until thoroughly ripe the roots will need a sufficient supply of plain water to prevent the foliage and plants from collapsing. Crops not in such a forward state may be hastened if necessary by closing as early as circumstances permit and maintaining a high temperature with the aid of solar heat during the day. Until the fruits commence colouring stimulative root waterings must still be applied and a humid atmosphere promoted in the usual way by damping down frequently and syringing freely morning and evening. Keep all lateral growths pinched back to one leaf. A. W.

MIDLAND COUNTIES.

Early Vines.—The laterals of early-forced Vines being now well ripened their shortening should be commenced. Remove about one-third of each shoot and all sublaterals from the remaining parts, but in doing this carefully preserve the principal leaves. This pruning will admit an increased amount of light to ripen the wood, and by concentrating the sap will assist the buds that are to produce fruit next season. Keep the borders thoroughly moist, and until the leaves wither liquid manure may be applied with benefit. If thrips or red-spider are present on the Vines wash them thoroughly with soluble paraffin insecticide, repeating the operation

at intervals. Apply it thoroughly to every part of the Vine with a syringe, working it well into the crevices about the spurs.

Late Vines.—The sunny weather of the past few weeks has been very favourable to the colouring of late Grapes and has permitted the necessary temperature being maintained without employing much fire-heat. The night temperature should be 65 degs. to 70 degs. The flavour of such varieties as Alicante, Lady Downe's, Gros Colman, and Apley Towers will be inferior unless the Grapes are ripened under the influence of a certain amount of fire-heat. In order to secure perfect colour the laterals should not be too severely thinned, and in very bright weather it is advisable to lightly shade the Vines. Keep the leaves clean and free from insect pests and promote a healthy growth by giving liberal supplies of water at the roots.

Hardy fruit.—The rainfall during the past few weeks has been quite inadequate to the requirements of all fruit-trees. The fibrous roots of well managed trees are near the surface, where they soon become dry, therefore watering must be frequent or the fruits will not develop or the trees form plump buds for next year. If proper attention is paid to the watering of the roots when the fruits are swelling no water will be necessary when they are ripening. Cordon and other wall trees that have carried heavy crops of fruit should be liberally fed with liquid-manure or some other manurial stimulant and be thoroughly washed with the garden hose. Trees making strong shoots require plenty of water, but no manure should be given. If any insect pests are present the trees should be thoroughly washed with an approved insecticide. Plums on walls have been netted to protect them from birds. Mice are often a source of trouble in these gardens when stone fruits are ripening, and traps are always in use. Wasps, up to the time of writing, are not so numerous as in some seasons. Choice dessert fruits may be protected from wasps by small muslin bags or by enclosing the whole tree in wasp-proof netting.

Chrysanthemums.—The earliest varieties have now set their buds, and should have the shoots tied out evenly, training the tallest growths in the centre. Use neat green-painted sticks, and in tying in the shoots endeavour to hide the stakes as much as possible. Attend regularly to the feeding of the plants, giving liquid-manure one week and an approved chemical manure the next. Guard against green-fly, and on the first appearance of this pest syringe the plants with Quassia extract or dust the buds with Tobacco powder in the evening and syringe it off the following morning. If mildew makes its appearance dust the foliage with flowers of sulphur, being careful to dust underneath as well as on the top of the leaves.

Gloxinias.—The earliest-flowered plants are losing their foliage, and the pots have been laid on their sides in a pit. After thoroughly drying off the tubers they will be removed to a room—where the temperature does not fall below 60 degs. and where they will be stored until the spring. Plants of a later batch are also showing signs of maturing and water is being gradually withheld.

Brussels Sprouts.—Keep the hoe at work as much as possible, especially amongst the earlier plantings, at the same time removing any yellow or decaying foliage.

Spring Cabbage.—Plants from the earliest sowing are now large enough for planting out. A warm, sheltered situation is chosen, and the heads should be ready to cut very early next year. A distance of 1 foot apart is sufficient. These will be followed in due course by plantings to form the main crop, and will be set out on ground that has been cropped with Onions. The soil will only need forking over lightly. When other work presses, these Cabbages may be planted without any preparation of the ground, loosening the intervening spaces afterwards.

Spinach.—The final sowing of Spinach will be made the first week in September. Stir the ground as frequently as possible between the rows of previous sowings and thin the plants to a few inches apart as soon as they are large enough. Later on, additional space may

be allowed them by pulling out every alternate plant.

Celery has made remarkable progress during the past three weeks, and this in spite of the Celery-fly being very prevalent when the plants were younger. It is probable that this pest will make its appearance again in the autumn, when its effects are far more serious than in the spring and early summer. As a preventive, fresh soot is freely strewn over the plants two or three times a week. Carefully remove all surplus side growths and decayed leaves, and where practicable give liberal doses of liquid manure in addition to ordinary waterings. Celery of good quality can never be produced if the plants are allowed to suffer from the want of water. From six to eight weeks at this season are required to perfect the blanching. It is a mistake to attempt to blanch too much of each stem at one time. About every fortnight a small portion of either brown paper or fine soil should be added, taking care that the whole of the leaf-stalks are drawn tightly together and the soil placed firmly. No attempt should be made to hasten the blanching of the later batches, as the longer this is deferred the more likely is it that the plants will pass through a severe winter unharmed.

Vegetable Marrows require liberal supplies of water at the roots during dry weather, and if manure-water is available it will be of great benefit. Keep the growth well thinned and cut the fruits as soon as they are large enough for use, whether they are required or not, or the plants may cease to bear before the season is over. F. W. G.

SCOTLAND.

Strawberry beds.—During the week the last of the Strawberries was picked. Immediately afterwards the mulch was taken away, runners cut off, and the beds thoroughly cleaned and hoed. It has not hitherto been the usual practice to do this work so soon. Strawberry beds, if neglected after the nets are removed, often get into a tangled and unkempt condition, and when they reach such a state much more time is consumed later in clearing them. The crop cannot be described as having been more than moderately satisfactory. The fruit was produced in large quantities, but, owing to the cold, wet, and sunless weather of June and the greater part of July, individual berries were small, although, with the improved weather at picking time, the colour was very good.

Raspberries.—A finish was made with the bottling of these, and the remainder of the crop will be used for jam-making as it becomes ready. With the out-and-in season, large pickings at any given time are not the rule, the crop ripening rather unevenly. Nevertheless, it is fully up to the average, and the quality is satisfactory.

Morello Cherries.—The nets taken from the Strawberry quarters were immediately transferred to the Morello Cherry wall, the trees on which are carrying a useful crop, which is now rapidly ripening. These trees have been remarkably free from pests during the present season; and a continuance of the fine weather at present experienced will do much to make the Cherry crop a moderate success. Close netting is needed, blackbirds being very fond of the fruit, while occasionally a squirrel will find its way into the nets. The squirrel, I think, is more partial to the kernel contained in the stone than to the pulp of the fruit, for I have frequently found hoards of Cherry-stones hidden at the foot of the wall when looking round the trees in the winter and spring.

Early Peaches and Pears.—In the case of these, and, indeed, of all fruits, the season is noticeably later than usual. At the same time there are symptoms that the time of ripening will not be much longer delayed. Therefore, nets were got into position in good time, and watering has been discontinued.

Figs are also likely to be later than usual. In the meantime no harm will follow if plenty of moisture and an occasional dose of weak liquid-manure be given from time to time.

Parsley.—Thinning was done in a long line of seedlings from a recent sowing. At the same time this was not overdone, as plants may be left a trifle more closely together at this season than may be considered advisable in spring. For the first time in these gardens—at least, to my knowledge—some damage was done to the Parsley by maggot. This had made some headway before it was noticed, but applications of somewhat strong ammoniacal water and soot water alternately soon cleared it out, and the plants have made a good recovery.

Peas.—Earlier in the season some anxiety was felt in respect of this crop, for, owing no doubt to the unfavourable weather, the pods, while very numerous, did not appear to be filling satisfactorily. With more genial weather this drawback ceased, and there is now a plentiful crop. Mildew, so far, is absent. I think that in some cases deluging the roots with water is to a great extent responsible for this fungus. Mulching or repeated stirrings of the surface are, I think, quite as effective as watering in the case of Peas. Late-sown varieties—e.g., Pilot—are looking very promising; and the following have been really good: Alderman, The Duchess, Duke of Albany, Telephone, and The Gladstone. The last has been outstanding, and bears, in proportion to its height, the heaviest crop of any Pea with which I am acquainted. I am certain, however, that the selections of some seedsmen are superior to those of others in regard to this Pea, and, if more expensive to buy, they ought to be preferred as being not only cheaper in the end, but of superior productiveness and flavour.

Late Potatoes.—In the course of the week, traces of rats were noticed, and a closer inspection showed that these had evidently been at work for some time. Without delay, both traps and poison were requisitioned, and a clearance has evidently been effected. The crop all over, so far, is highly promising, plants lifted here and there for a test turning up a good bulk of tubers, and those of a very fair size for the time of the year. As yet there are no indications of disease.

Roses.—Some time has been devoted to removing spent hlooms from the plants. The promise of a second display is encouraging. Such Roses as Hiawatha, Dorothy Perkins, Mrs. F. W. Flight—this family generally—are now at their best. The basal growths are coming along very quickly, and to prevent any risk of damage these are, meantime, being loosely secured to the supports.

Hydrangea paniculata.—Among shrubs at present in bloom some large examples of *H. paniculata* are noteworthy. These bloom exceptionally well year after year, and during the week, to assist them over the present period of dry weather, a light top-dressing was given. Some time ago cuttings were taken, and these, having rooted well, were potted off, and will be grown on for pots. During the ensuing spring, however, they will not be permitted to bloom.

Cold frames.—The various things which find accommodation at this time must not be allowed to feel any lack of moisture. English Irises have now ripened off their foliage, and will shortly be cleaned down, as will the early-flowering Gladioli, such as The Bride and G. Ackermanni. Afterwards a top-dressing of light, rich soil will be given. Ixias and Sparaxis will be similarly dealt with. If for any reason it should become necessary, no hesitation need be felt in putting out plants of Parsley in these frames above the Irises, etc. If removed before the permanent occupants begin to push in spring, no harm will follow. In the case of Cinerarias, Primulas, and such like plants careful watering is essential. During very bright days it is of benefit to these subjects if shade can be given during the hottest hours. In weather such as this, it is I think of advantage to the plants if the sashes are removed at night. The cool, night air and the dew are of service in hardening the foliage. In wet weather, however, the sashes should remain on the frames, but, of course, with the tilts in to their highest limit.

W. MCGUFFOG.

Balmie Gardens, Kirkcudbright.

CORRESPONDENCE.

Questions.—Queries and answers are inserted in GARDENING free of charge if correspondents follow these rules: All communications should be clearly written on one side of the paper only, and addressed to the EDITOR of GARDENING, 63, Lincoln's Inn Fields, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent each should be on a separate piece of paper, the name and address being added to each. As GARDENING has to be sent to press some days in advance of date, queries cannot always be replied to in the issue immediately following their receipt. We do not reply to queries by post.

Naming plants.—All who wish their plants to be rightly named should send fair examples of each—the stem, leaf, flower, or fruit. (Snippets of leaves and points of shoots are useless.) Not more than four plants should be sent in any one week by the same correspondent. Where more than one kind is sent they should be numbered. Of course the fruit should always be sent.

Naming fruit.—Several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruits for naming, these in many cases being unripe and otherwise poor. We can undertake to name only four varieties at a time.

PLANTS AND FLOWERS.

Mildew on Roses (Norah).—Dissolve an ounce of sulphide of potassium in 2 pints of hot water, then add enough cold water to make 2½ gallons. Use a syringe with a very fine nozzle, and take care that the underside of the leaves is thoroughly wetted.

Pruning Rambler Roses (A. T. Garthlands).—Any necessary pruning should be done as soon as the flowering is over. This consists in cutting out some of the old growths that have flowered, so as to encourage the young wood that starts from the base of the plant and on which the finest blooms are developed next year. As regards your Hollyhocks, the cause of the loss of foliage is more than likely due to the fungus which has been so destructive to the Hollyhock in recent years.

Ferns losing their fronds (C.).—When the fronds decay in the manner described it is a sign that the roots are unhealthy, or that the atmosphere is too damp. We should leave the top of the case off at night, and during the greater portion of the day sometimes. We do not consider Adiantums to be the best Ferns for culture in a case—they like more light than the generality of Ferns do, and they dislike moisture on the fronds, which should never be wetted in watering. If the plants still refuse to thrive, we should next season replace them with other kinds.

Water Lilies from seed (W. M. Crowfoot).—Provided you can get the seeds, they should be sown in the usual way in pans or pots. Any good fibrous loam with a little finely-sifted manure added will do. Make the soil moderately firm and level, and use pots, say, 7 inches or 8 inches in diameter. These may be filled to nearly three parts full with the soil, and at this level the seeds may be sown thinly. It is all-important in the raising of Water Lilies from seed that the pots be sunk sufficiently deep in the water to just cover the seeds, hence the reason for not filling the pots with soil. On the appearance of the second leaves, the seedlings should be potted into pots 4 inches across, using rich loam and manure. A tank placed over the hot-water pipes would answer quite well for the seed-raising, or shallow pots or pans placed inside larger ones would do equally well, inasmuch as all would be under control. The larger pans, of course, would require to be perfectly water-tight.

TREES AND SHRUBS.

Rhododendron with variegated leaves (M. B. Newman).—The leaf of Rhododendron Brilliant that you sent is partly natural, the growth of this variety coming quite golden,

afterwards becoming mottled, and finally turning the natural green. The leaf sent appears to be slightly sunburnt in addition to its natural colouring, which gives it a sickly appearance. We do not think that the plant is in any way diseased.

FRUIT.

Melon, adventitious buds on (D. W.).—The growths on the Melon are due to numbers of adventitious buds having been produced and to these branching again and again. The cause may be traced, no doubt, to some injury suffered by the plant, which it has attempted to heal, and from the callus these buds have grown. Probably the cause of the irritation, whatever it may have been, persisted, and so the plant made persistent efforts to overcome it, and at last the mass of buds sent was produced. The same thing is frequent on trees, and the curious and beautiful Bird's-eye Maple has its origin in something of this kind.

Nectarines rotting (Mrs. Bagshawe).—The disease is evidently what is known as "brown rot," but without seeing the tree and knowing something of the soil and the drainage it is very difficult to say what is the cause. We should be glad next year, should the fungus appear, if you would kindly forward a fruit in the initial stage of attack. After the fruits have stoned next year you should spray the tree at intervals with a solution of sulphide of potassium, using 1 oz. to 3 gallons of water, dissolving 2 oz. of soft soap in it before adding the sulphide. The young shoots you refer to are evidently those of the stock, and should be removed at once by clearing away the soil and cutting them off with a very sharp knife.

VEGETABLES.

Potatoes riddled with holes (Mrs. E. M. Birch).—The soil in which your Potatoes are growing is evidently full of small grubs which cause the injury to the tubers. The only way to get rid of these grubs is to give the ground a dressing of gas-lime at the rate of 2 bushels to 3 rods early in November, allowing it to lie on the surface for some six weeks and then digging it in. You should also procure a clean stock of seed tubers and plant in fresh quarters, as the tubers you have may possibly contain eggs or comatose grubs.

Peas falling (H. S.).—It is very difficult to say what is the cause of the failure of your Peas as you send us no information as to culture or material to help us in any way. We think that dryness at the roots is partly the cause. Did you prepare a trench into which was placed some rich manure, and water and mulch freely? Unless you did this, it is useless to expect late Peas to succeed, as they fall a prey to thrips and mildew and never do any good. Your soil may be very poor and hungry. Peas, more especially late Peas, like a good larder, and without this, failure is sure to follow.

Storing Carrots (F. W.).—Where Carrots are grown merely as a garden crop, and only in sufficient quantities for the supply of the establishment—to maintain firmness, crispness, flavour, and colour, they are best stored out of doors in a cold, shady aspect in thin ridges. Cover with a little loose dry straw, then with some wood faggots, and let the whole be thatched over. Thus treated they will keep till the next summer free from growth and excellent in quality; while, if placed in sand and in a cellar, by New Year's Day, or sooner, they will be found to have begun to grow, after which they are tough and tasteless, with a heart like a stick. Young Carrots after the French fashion are, however, what we like, and it is quite possible to have them all the winter, and, indeed, the whole year round. Let them be sown in July and August, and in December mulch them lightly, previous to severe frost setting in, with straw, Pea haulm, Fern, evergreen boughs, etc. You will thus have capital young Carrots every day during winter.

MISCELLANEOUS.

Tennis-lawn in bad condition (C. T. Lawn).—Seeing your lawn is in such a bad condition, the only thing you can do is to lift the whole of the turf and when doing so pull out the coarse Grass. When this has been done you ought to have the ground forked over and

carefully levelled, raking the surface fine and making it firm. You may then relay the turf. Top-dressings will do no good in the way of levelling up the depressions that appear in the lawn. A top-dressing of fine soil in the spring would do a lot of good.

SHORT REPLIES.

Subscriber.—We know of no book dealing specially with the subject you inquire about, but any queries relating thereto we shall always be pleased to answer.—*Monica Leuer.*—Without seeing your Roses and Hydrangeas it is quite impossible to suggest any reason for the failure. We should advise you to ask some practical gardener in the neighbourhood to look at them, and then some reason for the failure may be found.

OBITUARY.

LORD REDESDALE.

The daily papers have already given full details of the life and work of this distinguished public servant, whom I had the pleasure to know and often to see in his beautiful garden at Batsford. He was a man of many parts in diplomacy, and much travel in Russia, Japan, and China. Manly and cheerful, he was well liked everywhere. Among his activities he took kindly to the garden, and had the finest collection of Bamboos in the open air in Europe. He was the author of the "Bamboo Garden," which was reviewed in these columns years ago. He was also a successful breeder of Shires and had built a very fine house on his estate at Batsford. He was for some years at the Office of Works, and in that capacity he had much influence for good in the parks under his charge.

BUSINESS NOTES.

Hyacinths, Tulips, Daffodils, Anemones, Sweet Peas, Carnations, Pinks, Pansies, Violas, and Roses all find a place in the catalogue just issued by Messrs. Dobbie and Co., of Edinburgh (seed merchants and nurserymen by appointment to the King). The firm also supply guaranteed Scotch-grown Potatoes, about which they have a useful footnote in their present list. We have no hesitation in saying that any one would be attracted by the choice of beautiful and practical things they offer.

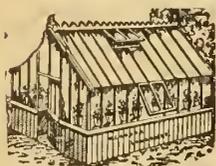

Mr. Robert A. Morris, bulb-grower and nurseryman, of 225, Bristol Street, Birmingham, is now issuing his descriptive bulb catalogue for 1916-17, and we notice that he emphasises the fact that for many seasons his principal stocks have been English grown. Gardeners may have the list on application. It contains an excellent selection, including many choice Roses. Mr. Morris is able to give good value, as he sells for cash only, and he endeavours to dispatch all orders within forty-eight hours of their receipt.

The cult of the rock garden has a very enthusiastic supporter in Miss Selina Randolph, of the Cottage, Chartham, Canterbury. She has just published her new list of 112 rock and border plants from pots, and we suggest that rock gardeners should write her for the list and make a selection of the plants, which she offers at a moderate price.

CLEARANCE SALE

Owing to our Works and Show Grounds being taken over by the War Office, we are offering the remainder of our Stock unsold at Special Low Prices.

THE LOSS OF THE CLEMATIS IN GARDENS.

[To the Editor of GARDENING ILLUSTRATED.]

SIR,—The excellent illustration in the issue of August 26th (page 423), showing the two sets of roots of the grafted Clematis, will come as a surprise to many who desire to make a success of these beautiful climbing plants. With the article I quite agree. The Clematis is the most beautiful of climbing plants, and the display given in return for successful treatment is such as to warrant its inclusion in every garden, however small. The washing out and severing of the stock from the natural roots I can thoroughly recommend, after having seen the success of large numbers so treated. I do not say that grafting is the only enemy of the Clematis, but I consider it is the greatest, and plants layered or struck from cuttings will produce vigorous specimens in a very short time. I see no reason why some of our nurserymen should not give layering and raising from cuttings more serious thought—even if they were compelled to charge a little more for the plants. The absence of the Clematis from the majority of gardens is a great loss, but so many have been planted and lost, mainly through having been grafted, that people have grown shy in using them. The Clematis is as hardy as a Briar, and when seen garlanding large shrubs or small trees with its charming blossoms, often for many weeks in succession, is a revelation.

The advice to plant at the base of shrubs where the roots are kept cool is good, and readers will do well to follow it. I know of instances where a few years ago plants were put out at the base of Magnolias and other flowering shrubs, and these have now become objects of great beauty. With the passing out of bloom of the shrubs the Clematis begins to flower, and the shrubs in a short time are draped with delicate trails of Clematis blooms. Slugs and mice give trouble in early spring by barking the stems, but these can be prevented by trapping.

E. MARKHAM.

64th Prov. Batt., Suffolk Regmt., Norfolk.

NOTES OF THE WEEK.

Yucca Whipplei at Exeter.—I am sending a photograph of *Yucca Whipplei*. The spike is 9 feet 3 inches high and is most beautiful with its light sprays coming out from the main stem. A hedge of Yews as a background adds to its beauty.—P. C. M. VEITCH.

[It would be interesting to know how far this fine plant is hardy in our islands?—Ed.]

Campanula Steveni (not nana).—I have never seen any special cultural hints for this species, but in my experience its behaviour is peculiar. It flowers early and abundantly, and is altogether desirable. It sends out abundance of rooting side-shoots, from which new plants may be taken. The main root seems to be annual, and the old plant dies away after flowering.—L. J. ROGERS, *Weetwood, Leeds*.

Diplacus (Mimulus) glutinosus and D. g. coccineus.—These flourish the year round in this district, growing 6 feet to 7 feet high, with like spread. Their free-flowering over an extended period makes them very attractive. The scarlet form, with its dazzling flowers is highly attractive, and preferable to the type, and quite as hardy, needing no winter protection whatever.—PENNICK JONES, *Delgany, Co. Wicklow*.

Verbena chamaedrifolia.—With me this now is, and has been for some time, a mass of dazzling scarlet. It requires a warm, well-drained position. I think this *Verbena* will prove hardier than some people imagine, but excessive wet would be fatal, therefore a sheet of glass should be fixed over the crown of the plant during the rainy season. Just now (the end of August) it is by far the most effective plant in the rock garden.—C. TURNER.

Spiraea Aitchisoni.—*Spiraea Aitchisoni* has flowered freely here this year, and is still very beautiful in the second week of August. It has now reached a height of upwards of 12 feet. For years it failed to flower with me, but after it did begin to bloom it improved annually and is this year finer than ever. It is evidently one of the plants which needs to be established to flower well, and even when a small specimen does bloom it does not give any idea of the true worth of *S. Aitchisoni* when it has attained a good size.—S. ARNOTT.

The Willow Gentian (*Gentiana asclepiadea*) as a cut flower.—This fine plant is not made enough of in gardens. Its graceful and flower-laden shoots have been before me in a London room for a week, and the flowers keep and open well. In the garden, though free in most soils, it is finest in that which is peaty or sandy and moist. Then the growth is handsome. It is one of the best plants for the choice mixed border, and excellent also for naturalising in a copse or Pine wood—its natural position.—W.

Cutting down the stems of hardy plants.—The other day I was much surprised to notice, in a neighbouring garden, that the stems of *Pyrethrums*, *Pæonies*, *Delphiniums*, and one or two other hardy plants had already been cut over to the ground-line. This is all too common, and it cannot be too strongly condemned. While it is bad for all plants it is especially so in the case of such as *Delphiniums* and *Pæonies*, which have little foliage round the stems. In all cases the stems of hardy plants ought to be left uncut until they have thoroughly matured. The premature cutting weakens the plants and will, if persisted in, do much harm.—KIRK.

Campanula isophylla Mayi.—In No. 4 greenhouse at Kew this distinct and good form has been for some time past demonstrating its fitness as a basket plant for conservatory decoration. Deeper in colour than the original *C. isophylla*, and distinct from it by reason of its soft downy foliage, it may be ranked as first-class among such things by reason of its free and profuse flowering and simple cultural needs. A few freshly-rooted young plants inserted in a basket of soil in spring will give, with good cultivation, a good account of themselves during summer and autumn, older plants well pruned back in early spring preceding them in their floral display.—E. H. J.

Iris reticulata.—To flower this well and keep the bulbs sound year after year two cultural points should be observed. (1) Plant in very light and deeply-drained soil; (2) see that the position is open and exposed to the sun throughout the season, so as to ensure the bulbs becoming thoroughly ripened. The second point I believe to be as important as the first, if not more so, for it not only secures free flowering but renders the bulbs practically immune from decay. During the heavy rains of autumn and winter, and even excessive summer rains, it will be best to protect the bulbs with small frames,

sheets of glass, or a deep-covering of sand. Grown thus I find the bulbs soon increase.—C. TURNER, 3, Kenwood-road, Highgate.

Eriophyllum cæspitosum (syn. *Bahia lanata*).—This, in the colder districts, may be lost in trying winters. It is a good border plant, but it is still better in the rock garden or wall, where its trailing growth, whitish leaves, and clouds of golden flowers are so effective. Sir Herbert Maxwell grows it well at Monreith, where the climate is milder than in many parts of the south-west of Scotland.—S. ARNOTT.

A brilliant autumn flower — Lobelia Cavanillesii.—I have known this both in France and England, and took a mild interest in it, but I never saw it so well grown as I have it this morning from Messrs. Robert Veitch and Son, of Exeter Nurseries, who say that it is wonderfully bright at the moment. It has the merit of distinction of colour as well as grace, and is one of the finest plants one could put on the rock border. Coming from Chili, it may want free soil and moisture—such things often do—but in any case it is a matter of trial, and rock gardeners cannot afford to neglect such a treasure.—W.

Lysimachia Henryi.—The genus gives us nothing more beautiful or choice than this free-growing Chinese kind, whose procumbent stems are now full of bloom in the rock garden at Kew. Rich golden in colour and distinct of leaf, there is about the plant an air of superiority quite unusual to members of the race which renders it desirable. Though easy of culture and usually free of growth, it is apt to disappear in winter in some localities, and should be propagated from cuttings to ensure retention of the stock. Blooming in August and later, when good flowering rock garden plants are scarce, it is worth a little trouble to perpetuate it.—E. H. J.

Shouldering Grapes.—Is this practice not carried out to an absurd extent? Some time ago I was in a vineyard where there was a perfect network of raffia between bunches and wires, which was, if the term may be used, highly artificial-looking. The only advantage which accrues from shouldering is that the bunches appear to be larger when growing, but such bunches, when ripened and cut, look very inelegant on a dish. Certainly such varieties as Trebbiano, or even, occasionally, Muscat of Alexandria or Gros Guillaume, may need a little support, but in a general way I would never hesitate to remove these ugly shoulders and concentrate all the vigour into the main bunch. A compact bunch is much more handsome when cut than a larger but loose-looking one, and certainly shows to better advantage on a dish.—KIRK.

Cornus macrophylla.—This very distinct *Cornus* forms a large tree in its native habitat, and in this country it is more tree-like in habit than any other species. Found wild in the Himalaya, China, and Japan, it has been known in this country about ninety years, though large specimens are rare. Trees up to 50 feet high have been reported from the East, and it is probable that plants growing under favourable conditions may eventually attain that size here. At all events it is wise when selecting a site for a young specimen to remember that it may ultimately form a tall, wide-spreading tree. The leaves are distinct by reason of their long, slender points. The creamy-white flowers, borne in large flattened heads during July and August, are succeeded by small blue fruits. When planting, a position sheltered from rough winds should be chosen, and care taken to provide rich loamy soil, for it is a gross feeder.—D.

Bidens dahlioides.—It is now five years since seedlings of this reputedly half-hardy plant were put out in a south border with a rather sheltered exposure. They have annually increased in size until they have made one good colony. At present (August 15th) there is a fine mass of flower, and to all appearance the clump will remain effective for some time. The deep green cut foliage contrasts well with the bright pink flowers, which are solitary and borne on long, semi-rigid stems, this making them useful for cutting. *B. dahlioides* is sometimes now known as *Cosmos dahlioides*, the latter name appearing to be the more suitable, as the flowers, in size, shape, and colour, are exactly similar to those of the half-hardy annual *Cosmos bipinnatus*. Close to *Bidens dahlioides* some plants of the fine blue *Salvia patens* have done equally well, having been planted, also as seedlings, at the same time.—W. McG., *Balmac*.

Campanula primulæfolia.—This very distinct and attractive species was noted in some quantity in a collection of herbaceous plants shown by Mr. J. Box on August 15th. As the "Primrose-leaved Bellflower," the specific name would appear somewhat far-fetched, despite which it agrees almost entirely with the description given by "Don" in his "Gardeners' Dictionary." So far as I remember it has not been exhibited before, though it is certainly one of the more desirable of August-flowering kinds. Two feet or so high, the stems bristling with roughish hairs, the flowers, in axillary clusters, are disposed in a spicate raceme. They are erect, of violet-blue colour with intense purple base, in which respect they differ from "Don's" description, that writer referring to the flowers as having a "whitish downy bottom." That shown had the conspicuous purplish bottom characteristic of *C. versicolor*, and is certainly worth cultivating for its distinctness as well as late flowering.—E. H. JENKINS.

Madonna Lily from leaf.—It would appear from the note by Mrs. E. Towgood (page 408) that she is impressed with the view that the Madonna Lily she has just flowered has sprung from the leaf, though I doubt not it occurred as an axillary bud on a buried portion of the leafy stem. Your correspondent leaves readers in some doubt as to whether the leaf from which she took the tiny bulb was a partially buried stem-leaf or one of the much larger radical—i.e., basal—leaves common to this species, and which come into being soon after the flowering is over for the year. Bulbils on the stems of certain species of Lilies are common enough. Occasionally, too, they occur on the buried portion of the stem in kinds not prone to produce them in the upper parts of the plant, their occurrence in such places in the Madonna Lily being unusual, though not unknown. On the bulb scales of this kind, however, they are much more frequent; indeed, it may be—is—increased in this way commercially. I have never seen a bulblet occur on a true leaf, however.—E. H. JENKINS.

—In the issue of your paper of August 19th (p. 408), at the foot of a paragraph relating to the growing of a Lily from the leaf, there is a note to the effect that the Editor has never heard of the Lily being increased in this way. In connection with this Mrs. Towgood may perhaps like to know that the propagation of many species of Lily by leaf-bulbs is quite an old and very effective method, and one that I have myself practised for many years past. It is an excellent plan to cut the edges of the leaves saw-tooth fashion.—A. GROVE.

PLANTS AND FLOWERS.

ROSES.

ROSES ON TREES.

In most gardens there are ugly trees and useless shrubs, some living and some dead. Instead of removing such, they might easily be converted into beautiful objects by covering them with some of the many fine climbing Roses now to be had. In the case of dead trees, all that one need do is to dig out a large hole, incorporating a quantity of old turf and manure when refilling, or, if the soil is poor, filling the hole up again with some good loam. The soil is allowed to settle for a week or two, after which the Rose may be planted and tied up to the trunk of the tree, or the main branches in the case of a shrub. If the soil is good and the Rose strong it will not take long to clothe the dead, unsightly tree with foliage and flowers. When it is desired to use a living tree in this way it is necessary to sink a bottomless barrel or box in the newly-dug soil, planting the Rose in it. This will prevent the roots of the tree from running into the newly-moved ground and so hindering the growth of the Rose.

There are many varieties of Rose that would do admirably for such work, the quick-growing, slender-wooded species, such as the Ayrshires, sempervirens, Hybrid Briars, and Wichuraianas being particularly suitable. Bennet's Seedling is of quick growth and produces masses of double white blossoms. *Félicité Perpétue* (white) and *Flora* (bright rose) have a very graceful habit and are very free-flowering. In a warm, sheltered situation nothing could surpass *Sinica Anemone* for gracefulness and delicacy of colouring. *Una* is a hybrid of the common Dog Rose, and bears freely its long, pointed, buff-yellow buds and large semi-double cream blossoms. Among the *Wichuraianas* there are many excellent varieties, including the type *Wichuraiana alba*, with its innumerable sprays of single white blossoms and beautiful habit of growth. Other effective white varieties are *White Dorothy*, *Mrs. Lytton Dewhurst* (a white sport from *Lady Gay*), *Lady Blanche*, *Mrs. M. H. Walsh*, *Sander's White*, and *Silver Moon*. The yellow varieties are not so free-flowering, *Alberic Barbier*, with perfectly-shaped pointed buds of rich yellow and pale cream flowers, and *Jersey Beauty*, with large single blossoms, being the two best for the purpose. *Rene André*, *Leontine Gervaise*, and *Desire Bergera* are the finest of the bronzy-tinted varieties. Of the many pink sorts *Dorothy Perkins*, *Lady Gay*, *Minnehaha*, and the delicate pale salmon-pink *Lady Godiva* are the most effective, the single-flowered *Joseph Lamy* being also very pretty. In bright reds we have *Excelsa*, *Coronation*, *Sodenia*, *Troubadour*, and *Edgar Andrieu*, all producing large trusses of double blossoms, *Miwatha*, *Delight*, and *Ersinach*, giving equally large bunches of single, golden-eyed flowers. *American Pillar* we must not forget, for this is, perhaps, the most effective of all rambling Roses and certainly one of the most vigorous and healthy. It has handsome leathery foliage, this forming a fine background for the enormous pyramidal bunches of single carmine-pink flowers.

In order to give the plants a good start it is advisable to cut them down to a foot from the ground in the March following planting, after which they will need no attention save merely an occasional tie to secure the stronger growths.

NOTES AND REPLIES.

Sweet Briars.—These, perhaps, are not now so generally grown as was at one time the case, yet where space can be afforded a hedge of Sweet Brier adds much to the attractiveness of the garden. The old Sweet Brier has to a great extent been supplanted by the varieties raised by Lord Penzance. I have, at one time or another, grown the whole set, sixteen in number, my favourite being Anne of Geierstein, a very vigorous Brier, and quite distinct from all the others in respect of the colour of its blooms, which are freely produced in July, and though the display only lasts three weeks or so, yet the perfume of the plant remains throughout the season. The blooms remind me of those of Gloire de Margottin Rose, in point of colour.—W. McG.

"Austrian" Briars.—The other day, while looking at a well-flowered piece of the yellow variety, Harrisoni, I was asked why the name

very bare below unless well attended to. The beautiful soft copper colouring of the petals, with their bases of yellow, is always appreciated against the pretty foliage.—SUB ROSA.

Rosa altaica.—Classed with *R. spinosissima* as variety *altaica*, this is a much bolder and more vigorous plant than the type. It is in bloom, as is its wont, for the second time. It is one of the earliest of Roses, also, and is either in early summer or now distinctly ornamental with its pretty foliage and large single flowers of a beautiful shade of creamy-white. One of my plants, which is against a 6-foot wall, has long over-topped the wall by some 3 feet or so.—S. ARNOTT.

Rose Florence Forrester.—This H.T., sent out by Messrs. M'Gredy in 1914, is proving a worthy rival to other whites of the same class. It is claimed for it that it is an improvement on Frau Karl Druschki, and it is apparently a better doer and gives better flowers than Mrs. Andrew Carnegie. I have seen it in good condition this year, the high-pointed blooms, opening lemon and becoming

INDOOR PLANTS.

THE FAN PALM (*CHAMÆROPS EXCELSA*) IN A WILTSHIRE GARDEN.

THE plants shown in the illustration are growing in the open at Stowell Park, Pewsey, Wilts, the seat of Mr. J. H. Smith-Barry. They were planted by the present owner eighteen years ago, and for the first few winters were protected by wattle hurdles to keep off snow, but for many years past they have been exposed to all weathers. They flower annually, and in some seasons seeds ripen. At the present time there are seeds from last year on the plants. The seeds are sound, and, to all appearance, good. The height is about 9 feet 6 inches. The group contains plants of both sexes (two of each). Encouraged by the growth of these, two young plants of the same species have been planted near.

The Fan Palm (*Chamærops excelsa*) in the open air at Stowell Park, Pewsey, Wilts.

"Austrian" was used in connection with this family. I had to confess my inability to answer the query, and now, after some research, I am no nearer to a solution. The family, of course, is correctly *Rosa lutea*, but when, or why, the epithet "Austrian" was applied to these Roses I have not, in any of the books at my disposal, been able to ascertain. Perhaps some specialist in Roses may be able to enlighten me.—W. McG., *Balmac*.

Rosa Willmottæ is one of the most delightful of the newer Rose species, and when seen as a large plant is an object of much beauty. At Orchardton, Kirkcudbrightshire, there is a fine plant, some 9 feet or 10 feet high, and when in bloom the other day it was very handsome. The delicate pink flowers are borne in long, arching sprays. The colour certainly looks pale when growing beside the deep-coloured *R. Moyesi*, but by itself it is very attractive.—S. A.

Penzance Brier Lady Penzance.—This, one of the most distinct of the Penzance Briars, is flowering unusually well this season, and a large plant against a wall, but not too closely trained, is specially fine. In some soils Lady Penzance does not look happy, and becomes

pure white, being of exceptional quality.—SUB ROSA.

Wichuraiana Rose White Dorothy Perkins.—A great defect of White Dorothy in many gardens is the pink tint it appears to show; while in other gardens it is not such a good doer as Dorothy Perkins. I saw a fine weeping standard of it in the Rose garden of Mr. Brown, of Knockbrex, Kirkcudbright, the other day, and it was there exceedingly fine in every way. The colour was pure white.—S. A.

Rose Lady Swaythling.—This is a beautiful new *Wichuraiana*. The flowers are single, borne in trusses, but not so dense as those of *Hia-watha*, consequently, the habit and general appearance are very graceful. The colour is rose-pink with an almost pure white centre. It was raised by Messrs. W. H. Rogers, Ltd., Southampton.—G. G. B.

Rosa alpina Malvi.—The alpine Roses come in early, and are generally enjoyed by those who like single flowers. *R. Malvi* is perhaps the deepest coloured of all, being of an intense crimson. On its own roots it soon spreads into a good bush.—SUB ROSA.

These are looking very healthy. The garden is nearly 500 feet above sea-level.

W. FREWIN.

Littonia modesta.—This is a near ally of the well-known *Gloriosa superba*, which, however, requires the temperature of a stove for its successful culture. On the other hand the *Littonia* may be grown in a greenhouse. It passes the winter in a dormant state, at which time the curious tubers, like those of a small *Gloriosa*, must be kept dry. The better way is to allow it to remain in the pot in which it has flowered, and then, in early spring, turn the soil out of the pot and pick out the tubers therefrom. Then repot them in a mixture of loam, leaf-mould, and sand, and place in the warmest part of the greenhouse. Given just enough water to keep the soil slightly moist the young shoots will quickly make their appearance. These soon mount upward, supporting themselves by slender tendrils. The drooping flowers are bell-shaped, each a

couple of inches or so across, and of a bright orange colour. This *Littonia* is a native of Natal, whence it was introduced about 60 years ago. A near ally also from Natal is *Sandersonia aurantiaca*, between which and the *Littonia* there is at times a certain amount of confusion. The *Sandersonia*, however, is a less pronounced climber than the *Littonia*, while the flowers are broadly urn-shaped.—W. T.

CAMELIAS.

THE oft-repeated query to the Editor as to the cause of bud-dropping in *Camellias* would lead to the inference that this is rather a common trouble. It is a pity enquirers do not always specify if their trees are in pots or planted out, as this would render it considerably easier to give the necessary information. In either case, however, the trouble is attributable to several causes, although mainly arising from too much or a lack of water and imperfect ripening of wood. Given old-established plants, either in pots or beds, with suitable soil and the necessary amount of drainage, water may be given freely. Another mistake is to give stimulants too early; healthy plants will make

and if a little natural shade is not available it is well to give them the benefit of an improvised skeleton structure over which a bit of tiffany can be stretched during the hottest part of the day. Too much exposure to sun, necessitating constant watering, has a tendency to quickly impoverish the soil.

Camellias have gone through varying vicissitudes of fortune so far as public favour is concerned. At one time very popular and commanding quite high prices in the cut flower market, they gradually declined until hardly so much in request as many of the annuals. Now they are once again coming into favour, but never, I fancy, will they be grown so largely as in bygone years. E. B. S.

NOTES AND REPLIES.

Aotus gracillima.—This is one of the most graceful of hard-wooded plants, the long, slender branches arching over in a graceful manner. During the flowering season (May and June) the plants are clothed with closely-packed small Pea-shaped blossoms of a pleasing yellow colour marked with bright crimson, and remaining fresh for a considerable time. Introduced from New Holland in 1844,

Pinks in the rock garden at Friar Park.

quite enough growth as soon as the flowering season is over with pure liquid, and anything in the way of stimulant causes soft, luxuriant foliage which it is difficult to ripen satisfactorily for another season's flowering. The stimulant may come in as soon as the buds are formed and thinned, and there is nothing better for the purpose than cow-manure. I noted above the non-ripening of wood as one of the causes of bud-dropping, and this, in its turn, is the outcome of sappy growth or injury to foliage from insect attacks or imperfect ventilation.

One comes into contact with old glass structures in different parts of the country occupied wholly or in part by *Camellias* where the ventilation is very imperfect, and, if this is so, care must be taken to utilise it to the best advantage, and also in the early stages of growth to put on a light shading if the sun happens to be powerful. A very light material will suffice, and if this is not available or it is difficult to fix, a substitute may be found in the shape of a slight sprinkling of Summer Cloud. It is not often that one finds injured foliage on plants in the open, whether planted out or standing out in pots for the summer months, but so far as the latter are concerned it is not advisable to stand them in a very exposed situation,

this *Aotus* needs the same treatment as the general run of hard-wooded plants. A compost made up of peat, with the addition of a little loam and a fair proportion of silver sand, will suit it well. Effective drainage is also very essential. In repotting, the soil should be pressed down very firmly, and the old ball of earth must not be buried deeper than it was before. Watering should be carefully done. As soon as the flowers are over, the long shoots should be cut back, and when the young shoots make their appearance is the time to repot.—K. R. W.

Achimenes coccinea.—This, which is I believe the oldest member of the genus, cannot in size of flower compare with many of the garden varieties. It is, however, very free-flowering, the bright-scarlet blossoms being borne in great profusion, and that, too, over a lengthened period. The dark green of the leaves serves as an admirable setting to the flowers. It may be grown in pots, deep pans, or baskets. In the last it is seen to great advantage.—W. T.

Browallia speciosa.—This can be grown to flowering size from seeds in a few months, the plants being most useful in a cool and light house. The foliage is a pretty shade of green, with which the numerous pale-blue flowers, each with a white eye, contrast well. Good useful plants may be had in pots 5 inches or 6 inches in diameter.—KIRK.

ROCK, ALPINE, BOG, FERN, AND WATER GARDENS.

PINKS FOR THE ROCK GARDEN.

ROCK GARDENS are so numerous in our country now that the plants which adorn them the best may well deserve thought. We would say that the first place should be given to the Pinks for several reasons. First of all, some are native and hardy plants. Secondly, the wild kinds are parents of some very good garden plants, the beautiful race of Carnations, for instance, which comes to us from a wild Pink (*D. caryophyllus*). The Pinks, another beautiful race, come to us from another wild Pink (*D. plumarius*). That in itself is a good credential, as it gives us constitution and hardiness. Apart from the numerous kinds raised in this way, there is a number of wild kinds which also deserve attention. Naturally, these plants are natives of the rocks and stony places, and, therefore, they do not thrive in what we call heavy land. Heavy clay land, or cold, low-lying land, in winter sickens the plants or produces a sickly growth. The best place for them is the rock garden, of which we give a fine example here. In a recent visit to Sir Frank Crisp's garden we were delighted with the effect of the Pinks in many aspects. Sometimes they are hybrids raised from the Cheddar Pink and its allied kinds, and often very difficult to name, but that does not make them any the less valuable for the work.

Distinct wild kinds one must have, but a number of garden kinds are easily raised and increased by seed as well as in other ways. The Sweet William, which comes to us from the wild Pink, is one of the very best of garden plants known. I have got in an Oak plantation some plants, mostly from scattered seed many years ago, and they are still vigorous. In gardens one sees it occasionally treated as a biennial—believing in its short life—but in certain soils it becomes quite perennial. The Maiden Pink is a pretty native plant, excellent for the rock garden, too.

It will be understood that the great group of hybrids like Pinks, Carnations, and Sweet Williams, which are usually grown in the flower garden, have no place on the rock garden. For that we have a large choice in wild species, and also the numerous hybrids that arise from them.

W.

NOTES AND REPLIES.

Dianthus graniticus.—The flower of the Granite Pink resembles that of the Maiden Pink (*Dianthus deltoides*), but is larger in all its parts. It is an excellent Pink for the front of the border, the rock or wall garden, or the moraine. The flowers are of a bright crimson, with, towards the base, a deeper shade. The white variety is not often recorded, but it comes occasionally from seeds, and seems to come fairly true if the seeds are gathered from white-flowered plants.—S. ARNOTT.

Veronica incana.—The number of species of *Veronica* is legion, and some are not particularly interesting, but this is quite one of the best, with neat grey foliage, and bearing spikes, each 8 inches to 10 inches high, of dark-blue flowers. I do not find it so easily managed as some, as it seems susceptible to excessive damp in the winter, but it is well worth taking some trouble with, for it is beautiful alike either in or out of bloom.—N. L.

"The English Flower Garden and Home Grounds."—New Edition, 12th, revised, with descriptions of all the best plants, trees, and shrubs, their culture and arrangement, illustrated on wood. Cloth, medium 8vo, 15s.; post free, 16s. 6d. Of all Booksellers or from the office of GARDENING ILLUSTRATED, 63, Lincoln's Inn Fields, London, W.C.

OUTDOOR PLANTS.

MECONOPSIS PRATTII

SOME doubt having arisen as to the correct name of the *Meconopsis* here figured and which we received as *M. sinuata latifolia*, we sent flowers to Sir David Prain, who has made a special study of the genus embodying this in the *Kew Bulletin* No. 4, 1915. He kindly sends us the following notes:—

This is a form of one of the two very distinct plants for which the name *Meconopsis racemosa* has been used, and of the two it is the one which does not agree with the picture published by the late Mr. Maximowicz. In the *Gardeners' Chronicle* it has been figured as *M. racemosa*, and more

Meconopsis Prattii.

recently has been alluded to by Mr. Farrer in the same journal as *M. Wardii*. I agree with Mr. Farrer in keeping out of *M. horridula*, of which the *M. racemosa* pictured by Mr. Maximowicz is a variety, but have thought it better to use the name *M. Prattii*, which was given to this plant twenty years ago, rather than use the one more recently proposed by Mr. Farrer. I know that Professor Balfour thinks this right, and I understand that Mr. Farrer also thinks the same. There is one doubtful point still connected with this plant. It may be the real *M. racemosa* which Mr. Maximowicz described in 1876, though we know that it is not the *M. racemosa* figured by that gentleman in 1889. This point we cannot settle till

this war is over and some competent botanist is able to examine Maximowicz' original dried specimens. Till that is done we shall be safer to use the name *M. Prattii*.

INCREASING TUFTED PANSIES.

Will you kindly tell me the best time for taking *Viola* cuttings, and how the soil should be prepared, and what attention is necessary in the early days?—IGNORANT.

[The best way of securing stock of these plants is to plant a few reserve clumps in the border somewhere and treat as follows:—When the first flush of bloom is past, cut the plants closely over to within 1 inch of the soil or thereabouts. At this time the base of the plant is crowded with fresh young shoots that cannot grow by reason of the crowded tuft above, but

cuttings, or, by leaving a fortnight longer, make up a border of good soil in a shady spot, and transplant them there. This method produces the finest plants with a minimum of labour, and where large numbers are required from a plant or two it is best to first pull out the more prominent growths, and repeat this operation as the cuttings are fit for removal.

PREPARING GROUND FOR PLANTING.—To grow the Tufted Pansies well the soil should be deeply dug and heavily manured. Much depends on the character of your soil, however. Should it be light and sandy, well-rotted cow-manure should be incorporated freely, as this is very retentive of moisture, and cool also. In the hot weather the roots revel in quarters that have been trenched, the results in the flowering period amply repaying one for the extra trouble and expense incurred. Should your garden soil be heavy, with a clayey sub-soil, incorporate freely well-rotted horse-manure. The quarters for the Tufted Pansies should be taken in hand as early as convenient. The ground should be treated in the way suggested sufficiently early to leave the surface in the rough for a week or two to sweeten, and for the weather to render it friable before the planting. You may safely plant out the Tufted Pansies during the first or second week in October. Little pieces planted at that time will make beautiful plants by the early summer, and they should be studded with blossoms from April (possibly earlier) onwards. This is the advantage of autumn planting. Should you prefer to plant in the spring see that the quarters are dug in the winter and the surface left rough for the frosts to pulverise and sweeten it.]

NOTES AND REPLIES.

Mimulus outside about 1 foot high.—Will these stand the winter outside? How are they propagated, and when should this be done?—MOORCROFTS.

[We are not in a position to render you much assistance, not knowing to what kind you refer. Had you sent us the name of the plant, or a specimen of it, or even given us the colour, we should have had something to guide us in the matter. All we can say is that if it is some form of *M. luteus* it is approximately hardy, and may be increased by division quite easily. If reference is made to any of the large-flowered hybrids, these are less hardy and best increased by means of seeds or cuttings. Hardiness, however, varies with localities, and your note does not even give the district from which you write.]

Lactuca Plumieri.—This is now in bloom, a large clump of it at the back of the herbaceous border attracting attention. With good cultivation it attains a height of 7 feet or 8 feet, with flower-spikes of a foot or 18 inches long. It is easy to grow in any good loam, and seems indifferent as regards position, though it is perhaps more effective in partial shade, as the blossoms then last longer. Self-sown seedlings often spring up round the plant so that there is no difficulty in getting a good stock. At the same time, it need never become a nuisance, as it is quite easy to keep the clumps within bounds.—N. L.

Convolvulus althæoides.—Despite its reputation as a weed in some gardens, and one that cannot be tempted to grow in others, this delightful species, from the Mediterranean region, is one of the most admired of its genus when seen in a thriving condition. On chalky soils, and not infrequently those of a stony nature, in southern counties it usually grows apace, and a patch of it with a few dozen

which, with light and freedom, quickly take on a fresh lease. After cutting down, lightly fork the surface soil round about the tuft, and give a thorough soaking of water. Procure some fine soil, well mixed with sand, and surround the plant with this to a diameter, say, of 6 inches beyond the tuft; also sprinkle some of the same soil in the centre of the plant, and presently wash it down with water from a fine-rose can. For a time, if the weather be dry, continue to sprinkle the plants daily each evening with water. By following this carefully the fresh growths in the centre will root into the new soil, and may, a month after the cutting down, be detached and treated as cuttings, though, in this instance, these will be mostly "ready-rooted ones." These young, unflowered pieces you may either insert in a frame as

of its handsome pink flowers expanding to the sun is a great attraction. In localities where it shows an inclination to spread freely its roots should be restricted. At Friar Park, where it was in good flower recently, it does not require any coaxing. In former years, at a somewhat earlier date, it had almost sheeted its allotted space with a colour all too rare in the garden at any season. At Kew recently other two species of the genus were doing well in the rock garden, *C. mauritanicus*, with bluish flowers, and *C. cantabricus*, which has pink flowers not so large as in the above-named. All are free-flowering and suited to sunny positions.—E. H. JENKINS.

Naturally-grown Clematises.—It is a pity that more people do not plant the large-flowered Clematises at the base of small, thinly-branched trees rather than against walls. It is probable that the plants would be generally more satisfactory with their roots on the shady side of a tree and the shoots exposed to full sun, than when the roots are exposed to considerable sun-heat, as is often the case when plants are grown against walls. As a rule it is unwise to put the plants close to the trunk of the tree. Rather allow them to stand near the outskirts of the branches and guide the young Clematis shoots to the first branches by the aid of strings or a stake, after which they will look after themselves. It is wise to dig a hole for each plant and provide good soil to give it a start. Laburnums, Almonds, Apples, Pears, Cherries, etc., may all be used as hosts for Clematis, whilst vigorous kinds can also be planted to grow over evergreen bushes, such as Laurels, Hollies, Magnolias, and Yews. Not only are Clematises seen to advantage from this natural manner of growth, but other kinds of climbers also can be grown in the same way. Vines reaching the tops of tall trees, Roses covering large Yews and Hollies, and Wistarias rambling over trees and bushes are a few subjects that are never seen to better advantage than when allowed absolute freedom.—K.

Propagating bedding plants.—This, in connection with bedding plants should be persevered with and—Calceolarias excepted—brought to a close as soon as circumstances permit. Pentstemons have made a good deal of growth of late, consequently plenty of cuttings which can be taken off with a heel is now available. These can be propagated in the same manner as Calceolarias or in pans or boxes, the first-named being the best way if a good number of plants is required. Pentstemons have been so much improved, and can now be had in such a variety of shades, and are moreover so free-flowering, that they are doubtless destined to play a still more important part in bedding arrangements in future than they have done in the past. Another great recommendation in their favour is that they are hardy, the plants or cuttings needing the protection of a cold-frame or pit only in the winter months.

Begonias in the open air.—Looking round some cottage gardens the other day I was struck by the difference in the behaviour of Begonias. In one or two instances the plants were fine, in others they were of but moderate growth, and in some an absolute failure in every way. Begonias are at best miffy subjects, and, especially in cottage gardens, might well be discarded.—KIRK.

Oreocome Candollei.—This is a very handsome, fine-foliaged plant belonging to the Fennel order, the large, finely-cut leaves being always admired. It grows well in any ordinary light garden soil, and if allowed to flower will ripen plenty of seeds, from which it can be readily increased.—N. L.

GARDEN FOOD.

COOKING LETTUCE.

DURING a spell of hot, dry weather many Lettuces will run to seed. It is difficult to use all of these before they become too bitter to make pleasant eating, but I have found that if the Lettuces are cut as soon as they show signs of running to seed they make a nice stew.

STEWED LETTUCCES.—Like all Greens, it requires a good many Lettuces to make a fair-sized dish of the stew. Cut the Lettuces early in the morning and place them in water. Do not immerse the whole plant in water, simply allow the stalks to stand in a shallow pan of water. Melt a little butter in a clean pan, and then wash the Lettuces in fresh water, break lightly into pieces, and drop into the pan. Simmer gently in their own juice and the melted butter until tender, chop finely, flavour with a little salt and pepper, and pile on squares of hot buttered toast, and serve very hot.

BOILED LETTUCCES.—The continental way of serving Lettuce as a cooked vegetable is to boil it in sufficient water to cover. Nutmeg or Cinnamon is always added in Belgium, but this quite spoils the flavour. When tender, add a little pepper, and stir in a dessert-spoonful of flour rubbed into the same quantity of butter. Simmer until the whole has thickened slightly, and send to table at once. Green Peas or sliced French Beans are generally added to the boiled Lettuce, and the two cooked together, but I prefer the flavour of the Lettuce when boiled by itself. It is much more delicate than when mixed with other vegetables.

PRESERVED LETTUCCES.—People who are fond of eastern preserves will like the stalks of Lettuces made into a preserve. Take as many stalks as you can procure. They must be very fresh and newly gathered. Remove all the peel, and cut the stalks into short lengths. Have ready some boiling water in which a little salt has been dissolved and boil the stalks for fifteen minutes. Dissolve $\frac{1}{4}$ lb. of sugar in a quart of water, add a small piece of crushed ginger, and simmer for ten minutes, removing all the scum as it rises. Place the stalks in this and simmer until they look clear, then turn the whole into a basin and leave for two days. Drain off the syrup add 4 ounces of sugar, simmer for ten minutes, and pour over the stalks. Leave for two more days, and then repeat the process, but instead of adding sugar use honey instead. After two more days simmer the whole for fifteen minutes and pour the preserve into jars, and cover with parchment paper or bladder. Keep for three months before eating, for the longer this preserve is kept the better it becomes. Cucumbers cut into cubes and preserved in this way also make a delicious sweet, but they must be kept for at least six months before eating, as otherwise the flavour has not mellowed, and is far from nice. H. T. C.

FRESH LIME FRUITS.

The following is from a handbook on "Lime Cultivation in the West Indies," published by the Imperial Department of Agriculture for the West Indies in 1913:—

The Lime is finding its way into favour, in America especially, and is more and more coming to be used instead of the Lemon. It is generally conceded by all who have become accustomed to the flavour of the Lime that this fruit far surpasses the Lemon in the delicacy of its flavour, and it is well known that when these fruits are grown together for household purposes, as often happens in the West Indies, the Lemon is only used when there are no Limes on the trees. A lime squash or limeade is much more refreshing than lemon squash or lemonade, and for use in cooking the Lime is generally preferred to the Lemon.

Limes which are to be shipped in the fresh state are picked from the tree while still green, but they must be full grown. They are allowed to quail for several days in the packing sheds. This process consists of a slight drying-out of the excess of moisture in the skins, rendering the Limes tougher and improving their shipping qualities, since a smaller amount of water is given off and shrinkage of the Limes in the package is less. Thus there is a smaller amount of slack, and consequently less damage from shaking. Each fruit is wrapped in soft brown paper and placed in the barrel, which is filled by being carefully packed with layer after layer of wrapped fruits. These should be firmly pressed down after every sixth or seventh layer has been packed.

The fruits are to be obtained from the principal London stores and from the West Indies Produce Association, Ltd., 4, Fenchurch-buildings, E.C.

NOTES AND REPLIES.

A cold dish for summer.—I should like to add my testimony to the excellence of Potatoes and Haricot Beans, dressed while hot, and eaten cold as salads. Floury Potatoes dressed with salt, pepper, plenty of good oil, and a little vinegar, with a little chopped Chives or Onions, thoroughly absorb the dressing and are like delicately-flavoured mashed Haricots when cold. Haricots should be carefully and gently boiled in such a way that when quite tender they have absorbed most of the water. Add a good lump of butter, pepper, salt, and Lemon-juice to taste, and when cold mask with a mayonnaise sauce and garnish with sprigs of boiled Cauliflower and sliced Beetroot. This is a nutritious dish which can well take the place of meat, the added fats greatly increasing the food value of the Beans.—MRS. CAROLINE ADAMS.

[A good dish for those who like Haricot Beans where there are no fresh Kidney Beans in the garden, but not, surely, a salad.—ED.]

Rhubarb leaves as food.—I never saw Rhubarb grown for food in France, and had the idea that the leaves were poisonous. I was therefore surprised to read this note in *Country Life*:—

RHUBARB LEAVES AS VEGETABLES.—Is it generally known in England that the large green leaves of the Rhubarb plant make an excellent vegetable if cooked in the French way? In war-time, where economy is studied, it may be useful to know exactly how these leaves are prepared, and it may prevent waste if you will publish the following recipe:—It requires about 3 lb. of Rhubarb leaves to make a dish sufficient for a family of six or seven people. The thick central vein is removed and the leaves thrown into a bucket and washed like Spinach. They are then placed in a saucepan of boiling water and boiled for about ten minutes to a quarter of an hour, passed through a colander to make a purée, and then turned into hot melted butter. Before serving, salt and pepper are added and a teaspoonful of flour in a small cup of milk is well mixed with the purée.

I have even read of a death from eating Rhubarb leaves.—W.

Stuffed Lettuces.—Take some large Cabbage Lettuces. Boil for a quarter of an hour, and dip into cold water and drain. Open the leaves without breaking them and fill the centre part with a good forcemeat and tie them up. Stew them a short time, then drain on a cloth. Dip them in batter and fry to a good colour. Cover with breadcrumb, and serve with white sauce.—*May Byron's Vegetable Book.*

TREES AND SHRUBS.

EUCRYPHIA.

LOVELY tall shrubs from Chile, and among the most precious grown in our islands in the southern counties and on high ground in the midlands. They are fine for association with the choicer American flowering shrubs and low trees like Magnolia and Stuartia in peaty or free soils, though they are, perhaps, not so much influenced by soil as by situation. So far as tried they thrive fully exposed to the sun.

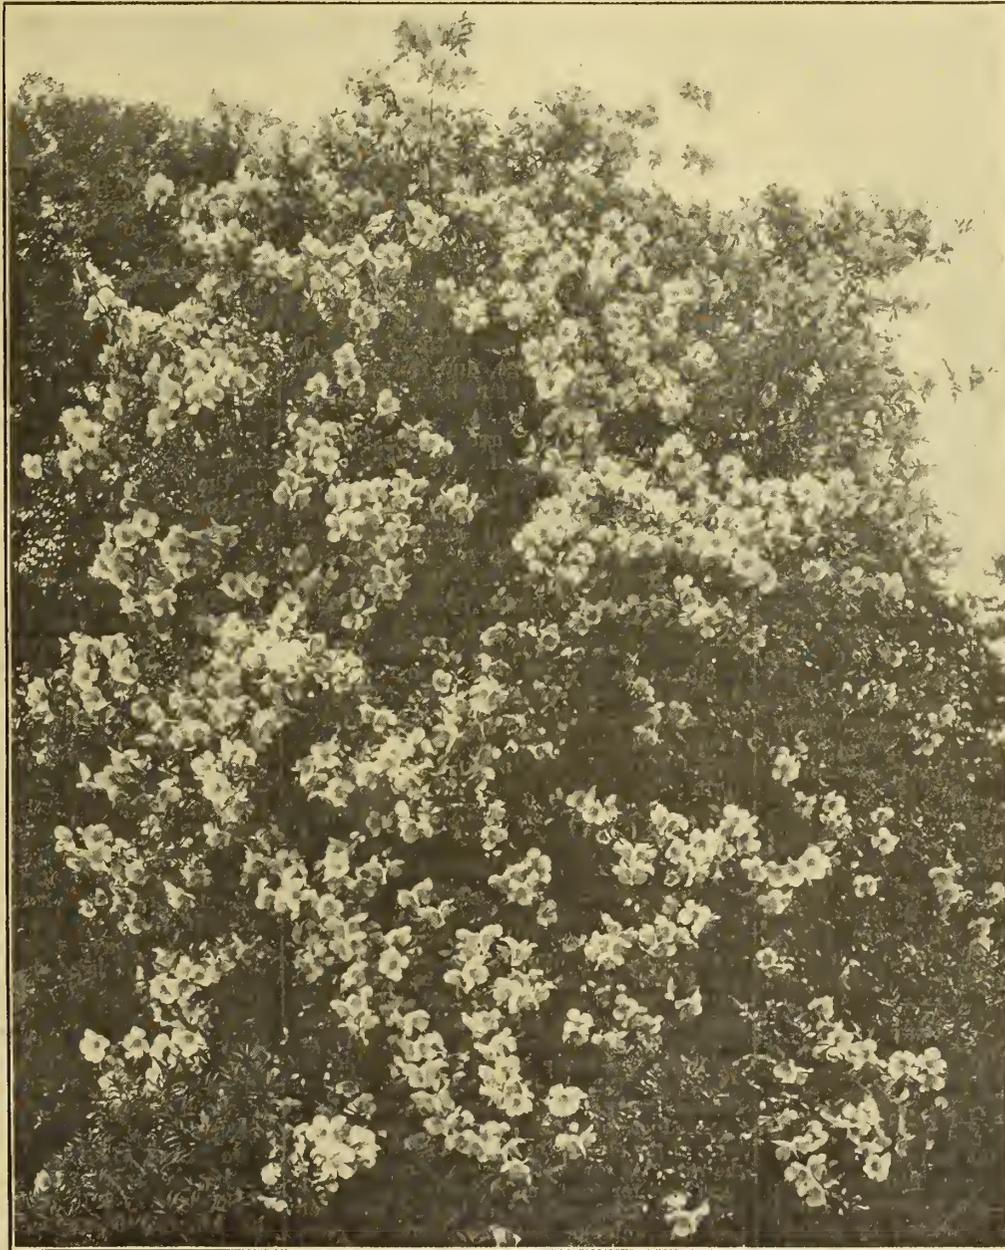

E. CORDIFOLIA, from Valdivia and the Island of Chiloe, is distinguished from *E. pinnatifolia* by its simple leaves, which are strictly evergreen, and, with the young wood, densely covered with down. The white flowers are each about 2 inches across. It is hardy at Nymans.

TWO INTERESTING WILLOWS.

SEVERAL new species of Willow have been introduced within recent years, and although many of the known Willows can hardly be looked upon as garden plants, the two new species to which attention is

but about the time when growth is completed for the year (August to October). Neither male nor female catkins have any special attraction, the charm of the plant being its graceful habit and pretty leafage. It was introduced to this country about 1910. The second species,

S. MAGNIFICA, introduced about the same time as *S. Boeckii*, is one of the most remarkable species of the many that are known. In China it is said to form a loose bush from a few feet to 20 feet high. Here it is known as an erect-habited bush with purplish young wood and prominent purple

Eucryphia pinnatifolia at Emmets, Ide Hill, Kent.

E. PINNATIFOLIA.—A native of Chile and fairly hardy, though there are many places in the southern midlands where it grows well. Each flower is from 2 inches to 2½ inches across and made up of four large white petals with a central mass of yellowish stamens. It thrives in light loam containing leaf-mould or peat. It was at one time increased by layers, but many of the young plants raised in that way were short-lived, and better plants are got from seeds. Stems are best not exposed but protected by dwarfier shrubs growing around. A second species,

directed are certainly worth consideration. They are named respectively *Salix Boeckii* and *S. magnifica*, both natives of China, differing, however, from each other in general appearance as widely almost as it is possible for Willows to do.

S. Boeckii is a graceful-habited shrub about 4 feet high, with slender, arching branches covered with small, oblong leaves, which are dark green above and glaucous beneath, both stems and leaves being very downy. The catkins are not produced in spring as is the case with most Willows,

buds. The leaves are, however, the interesting feature of the plant, for they are thick, oval, and up to 6 inches or 8 inches long and 5 inches or more wide, rather pale green above and glaucous beneath. The male catkins are said to be up to 7 inches long, and the female catkins sometimes 10 inches or more in length. Unfortunately, it appears to be rather tender, the early leaves being sometimes injured by cold. Both species should be planted in soil that is permanently moist, on the margin of a lake or stream for preference, where the roots can enter the water. D.

VEGETABLES.

VEGETABLE MARROWS.

THE Vegetable Marrow classes at exhibitions show that no one kind is favoured more than another, as is the case with most other vegetables. If we turn to the exhibitions of garden produce from the best private gardens, long, short, round, or Custard Marrows are invariably presented, but with this difference—that only white kinds are shown, whilst cottagers have just as much regard for green or mottled kinds as for white ones. Very probably, all other things being equal, it will be found that white kinds get the preference, but that is purely a matter of fancy, as when cooked it would be difficult to discover in what respect green-skinned kinds differed from white ones. Some kinds are more prolific than others; the smaller-fruited kinds produce more than large-fruited ones, but in the end the balance of actual bulk is about the same. Of course, if the fruits of the longer or larger kinds be cut whilst small, the relief given to the plants favours more abundant fertility. In the market gardens the Long White is preferred, and if somewhat ribbed, all the better. Still, a nice green specimen or two is not objected to, as these produce variety, and give some acceptable colour to the greengrocer's window. Cut while the skins are tender, Marrows soon become battered and disfigured. There are few directions in which reform is more needful in connection with market garden produce than our method of packing and getting it fresh and uninjured to the consumer.

Some little divergence of opinion exists amongst good vegetable judges as to the proper size or age for prize Marrows. They may be too big in some cases, but, if the skin is quite tender and the fruits even and handsome, it seems unfair that small fruits should be put before larger ones. It is a common rule to allow something for size in the case of cottagers' products, for these show by their exhibits that they think quantity to be of considerable merit. When, however, such kinds as Moore's Cream or the round Pen-y-byd are presented, of course size is out of the question, and here it is really one of quality and flavour. Marrows have become very popular; they are widely grown, and they prove valuable aids to the gardener during the summer months.

DEFOLIATING TOMATOES.

Is it right to take half the lower leaves of Tomatoes off when they have set three bunches of fruit? My employer says it is the worst thing that can be done. My object in doing so was to let the sun in, and also that all the strength should go to the fruit.—W. F.

[Cutting the leaves from Tomato plants, although necessary under certain conditions, should not be practised by rule-of-thumb. The foliage acts as a channel for conducting the sap to the fruit, although in cases of extra luxuriance the leaves assimilate the whole of the nourishment, and the fruit, even though it may set, usually fails to swell. On rampant plants partial defoliation is beneficial, cutting every alternate leaf half away three parts of the way up the plants, serving those that are left entire in the same manner in ten days' time; this will check growth generally, rendering the formation of fruitful trusses of flower more probable. When, however, the plants make only a normal growth and fruit freely, the less the knife is used amongst the foliage the better, as it should be borne in mind that, in addition to supplying the fruit with food, it acts as a protection against hot sun, the

latter sometimes burning or blistering the fruit, some sorts taking harm sooner than others. As autumn approaches and the fruit has swelled to its fullest, relieving the plants of leaves which hang immediately over the fruit is often imperative in order to give it a chance of ripening before frost sets in; indeed, some good growers then use the knife somewhat freely, their contention being that as the laying on of pulp has ceased, maturation by leaf defoliation is warrantable. This, of course, refers to open-air plants. The best way of guarding against excessive leafage and of reducing the need of defoliation to a minimum is to grow the plants in a manure-free soil from the first, and to assist with stimulants after the fruit is set.]

LETTUCE, SOWING FOR WINTER.

THE month of August is the best time to sow this important crop. Soil and situation have so much to do with results that I should hesitate to give any fixed date. Speaking generally, the latter half I should prefer. In one place I had to provide Lettuces daily through the year. This taught me not to depend on one sowing for winter. I always made three sowings from mid-August till the first week in September. Should the autumn be mild the first was too large, and if severe the last was not large enough to stand the winter.

Other things to avoid are sowing thickly and on rich soil. When the stems are soft they are full of water and the frost hurts them. Lettuces often stand the winter in exposed places and are killed in gardens with shelter and rich soil. Regarding sorts, Mr. Strugnell (page 372) speaks highly of Hick's Hardy White Cos. After trying many kinds I consider this the best Cos Lettuce. When looking over a large seed farm near London at the close of July I was told more of this was sold than all others for winter. From a flavour point of view and hardiness I have found nothing to equal the old Bath Cos. In Cabbage kinds the best is Stanstead Park. WEST SURREY.

NOTES AND REPLIES.

Runner Beans.—Many amateurs complain of the flowers failing to set, and there being only a sparse crop; but in nine cases out of ten the fault is want of food and moisture. The plants, having much top, have absorbed all the food from the soil, and just at the time the plants are called upon for increased exertion they cannot respond, the bloom drops, and only one flower in ten sets or comes to maturity. Runner Beans are gross feeders. In many parts of the country heavy rains have occurred of late, but little has reached the roots of the plants, the heavy tops throwing off the rain. As the roots are very dry, here is a clear case for food and moisture, and if both are given there will be no lack of pods well into late autumn. Moisture should be given liberally at the roots, giving food at the same time, and washing it down to the roots.

Celery.—While the present spell of warm weather lasts water must be applied to Celery trenches, or, if liquid-manure is plentiful, this should be given instead. The soil must, however, be in a moist condition first, otherwise the virtues of the liquid will be lost. The moulding of the plants in the earliest-planted trenches must as necessity arises be proceeded with after giving the roots a thorough drenching of water. Keep the leaf-miner under as far as possible by picking off the affected leaves and burning them.

Chervil.—A final sowing of this herb was made in a spare corner, well exposed to the sun, and in which it can be readily protected if necessary. The sowing was done broadcast, and the seedlings will be well thinned out when they are large enough.

FRUIT.

YOUNG VERSUS OLD STRAWBERRY PLANTS.

UNDER good cultivation, and on soils suitable for Strawberry culture, the plants are seldom purposely destroyed before they have produced three crops, and I have known them remain in a profitable state very much longer, this being principally due to a free use of liquid manure both during the winter and spring months. There are also soils so unsuited to Strawberry culture that it does not pay to attempt taking a second crop from the plants. Not that a second crop could not be had, but the quality is so inferior that the fruit is comparatively worthless. The question is: Do we attach sufficient importance to the value of young Strawberry plants? In other words, are not the older rows still left on the ground longer than they ought to be in very many cases? Old plants can be and very often are made to produce heavy crops of fruit, but what about the quality? How does this compare with that of the fruit of young plants on fresh ground? In the majority of instances the finest and also the best flavoured Strawberries are obtained from plants fruiting for the first time. It is also a fact that the first gatherings are obtained from young plants. In addition to young Strawberry plants being the first to produce ripe fruit of superior quality, they are also harder than the majority of those that have lost much of their pristine vigour, or any, say, that have given three good crops. The hardness of old plants being doubtful is another reason why fewer of them should be saved. It is sometimes urged in favour of their being retained longer than I advocate that the third and in some cases the fourth crops are much the heaviest, and if only a few of the fruits are fine enough for dessert, the rest are very acceptable for making into jam. That large quantities are required for the latter purpose there is no disputing, but why not grow one or two varieties especially for supplying this class of fruit? Instead of keeping the finer or high-class varieties on the ground longer than they continue to give the best dessert fruit, would it not be a better plan to clear them off the ground after producing two heavy crops and grow either Vicomtesse Héricart de Thury, or the old Grove End Scarlet solely for giving preserving fruit in great abundance? The fruit of either of these varieties can be made into much better jam than any obtained from choice sorts, and which may be much mixed both as regards size and quality.

Doubtless where extra pains are taken in the preparation of ground well suited to Strawberry culture, good room also being allowed between the rows and the plants in the rows, the third and even fourth crops are remunerative enough, but in how many cases are all the conditions favourable to this end? Too often deep culture and a free use of solid manure are followed by a rank growth of the plants, a plentiful crop of leaves and not very much fruit being the outcome. In other instances the fruit is produced freely enough, but owing to the plants running into each other it fails to ripen properly, especially in a wet season.

If ground is trenched for Strawberries this ought always to be done in time for a crop of early Potatoes to be taken off, and it will have settled down considerably accordingly. Trenching is not, however, possible in all cases, and, fortunately, it is by no means indispensable. Young

plants will produce good crops on un-trenched ground, and fruit equal to what is obtained by the more expensive and laborious preparation, and there is less likelihood of failure from the looseness and richness of the root-run. Most soils that have been well manured, dug a spit deep, and got into a free working condition will answer well for Strawberries, while if well-rooted plants are got out by the end of July or during the first week in August and well attended to, they will become sufficiently strong to produce a valuable first crop. G.

PLANTING VINES.

PLEASE give best method of planting Vines to come quickly into bearing. The site is a lean-to house on south of dwelling-house, outside border 20 feet 9 inches, inside run for Vines 20 feet by 16 feet. The old Vine border is on clay. I propose to concrete border at depth of 3 feet, as roots have always tended downwards

intended border at some 6 inches below the general level. This should have an outlet of a safe and reliable character, and should receive a good covering of stones or bricks. Nine inches of brickbats should also be laid upon the surface of the concrete, which should be 3 inches thick, and have a good fall from the wall of the vinery to the main drain already referred to. Should there be any probability of the roots finding their way into any uncongenial quarters, walls 4½ inches thick should be erected as a preventive. Where the subsoil is sand or gravel the necessity for artificial drainage is reduced to a minimum. For early forcing an inside border is the best, as then the roots are more on an equality with the foliage as regards temperature. The best compost is holding loam, adding mortar rubble and bones or bone-meal. Turves, Grass-side downwards, should be placed over the

been attacked, is one of the worst pests of the Apple. As soon as the leaves are down remove all loose bark from stems and branches, and apply a mixture known and sold as Woburn wash, taking the greatest care to work it into every part. The soil, too, beneath the trees should be removed down to the roots, and then spray the trees thoroughly. This wash contains caustic soda in addition to paraffin emulsion, and it can be purchased ready for dilution from any dealer in horticultural insecticides, etc. Next season be on the alert, and should stray insects appear, which is not unlikely, destroy them by brushing them either with methylated spirit or undiluted paraffin. It is only by the exercise of perseverance and the application of the remedies mentioned that you can hope to clean the trees. A friend of ours has found neat's foot oil a good remedy. This, being thick, should be warmed and applied with a brush, and will smother the insects.]

Peaches and Nectarines.—Early varieties are later than usual, but as the trees are relieved of their fruit they will be cleared of all useless wood that has carried the crop, and superfluous side growths shortened to their basal buds, afterwards giving the trees a thorough washing with an insecticide. Mid-season and late varieties are carrying good crops of fruit, and need all the sunshine possible to ripen the fruits satisfactorily.

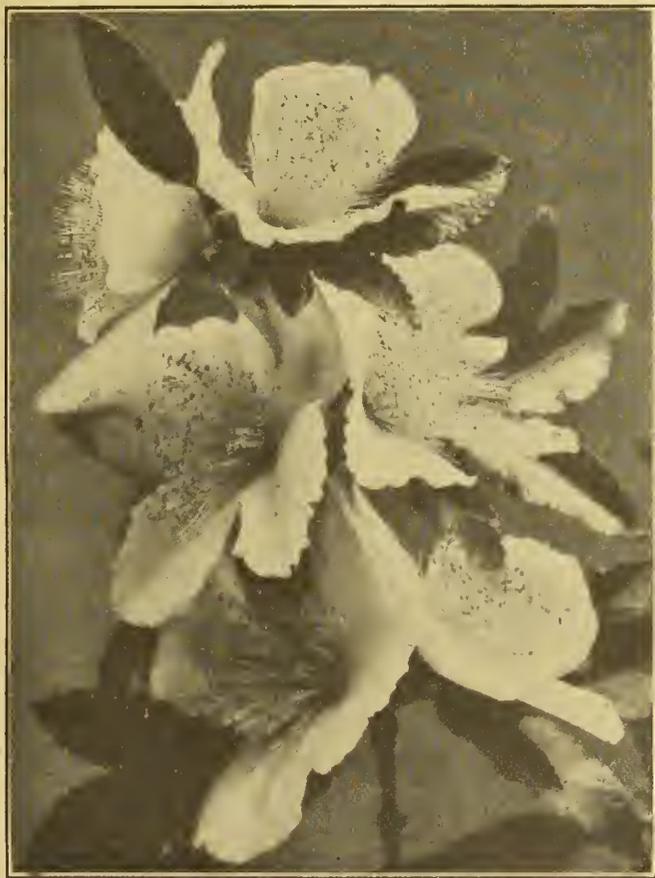

ROYAL HORTICULTURAL SOCIETY.

AUGUST 29th, 1916.

THE meeting held on the above date, though small, was interesting and representative. Hardy flowers, as might be expected, were well shown, comprehensive exhibits from Lindfield and Wisbech doing much in this direction. In both, the finer hardy flowers were seen to advantage, Montbretias and Phloxes playing a notable part. Exhibits of fruit, too, were of more than ordinary interest. Upwards of 100 dishes of Tomatoes representative of the 1916 Wisley trial of these fruits were sent from the Society's gardens there, cropping qualities and other things being demonstrated by showing a complete bunch and ripe, gathered fruits of each on the same dish. Several groups of Orchids were on view, among them many choice things.

HARDY FLOWERS.

These, while on the one hand materially assisting from the spectacular point of view, also demonstrated to some extent the wealth and procession of these that now obtain. In this connection the Montbretias were well to the fore for the first time this season, some excellent novelties being seen. The best of these were Queen of Spain and Citronella, shown by Mr. Sydney Morris, Earham Hall, Norfolk. The former of these, which gained an Award of Merit, is of large size, refined appearance, and rich orange colour, the other a smaller flower of canary shadings, is the most shapely we have seen, and would doubtless have secured honours had its flowering been less advanced. These Montbretias also stood out prominently and in considerable variety in a group staged by Mr. G. W. Miller, whose fine exhibit of Star of the East, much the largest variety yet raised, was a considerable attraction. It is of a deep tawny-orange tone. Prometheus is of intenser orange colour, to which its dark stems are a good accompaniment. Hereward is of refined yellow tone. King Edmund is also of this shade. White King Phlox in this exhibit had the merit of purity, handsome truss, and vigorous habit. The single pips, too, were very large; we thought them a little thin, though the exceeding wet of the moment was not favourable to such

Flowering shoot of *Eucryphia pinnatifolia*. (See p. 453.)

to clay in spite of regular manuring of border. I propose to take out old soil and fill with freshly-cut turves, Grass down, and loam from good pasture. What should cost of concreting be? I intend planting two Black Hamburgs, one Foster's Seedling, and one early black variety—which? The pipes for heating are part of house-heating apparatus. — S. L. HARTLEY, Yorkshire.

[The drainage of Vine borders is of paramount importance, but as regards this no rule can be laid down. Where the site is clay or approaching to it, concrete is needed to ensure an escape from the evils of water rising into the border, and to prevent the roots penetrating into the bad subsoil. In cold, low-lying districts the depth of outside border should not exceed 2½ feet at back, and, gradually diminishing towards the front, should not be deeper than 2 feet at that point. After the natural soil has been removed, and previous to laying on the concrete, a drain should be carried along the front of the

drainage to prevent the soil choking it. Firm borders, made piecemeal, keep the roots at home, and each new addition being sweet and fresh increases the vigour and fruitfulness of the Vines just at the time when they stand most in need of it. In addition to the two varieties you mention you should include Madresfield Court. Any local builder would give you an estimate of the probable cost of concreting. You should get a copy of "Vines and Vine Culture," Barron, price 5s. 6d., post free, from this office.]

NOTES AND REPLIES.

American blight on Apple-tree.—Would you kindly tell me what has attacked this Apple tree (Cox's Orange Pippin)? It is not all over the tree, which is young, and bears a fair crop this year. I have not noticed it on any other trees in the garden.—T. H. MORRICE.

[American blight or woolly aphid, with which the piece of branch you send has

things. *Lilium sulphureum*, a noble trumpet Lily, was very good, its powerful fragrance quickly attracting attention. The finest hardy plant shown by Mr. J. C. Allgrove was *Thalictrum dipterocarpum*. No other species can compare with this in gracefulness or the pretty effect of its violet-coloured sprays. As shown, it sprang from a mass of double white *Gypsophila*. The most comprehensive exhibit of these flowers was that arranged by Mr. J. Box in whose lot *Rudbeckia Herbstone* appeared as a novelty; indeed, in the yellow "Cone-flowers" it is the most refined and beautiful that we know. Four feet or 5 feet high, the clear, soft golden or butter-yellow of the informally-arranged florets is very telling, and a group in the garden would be effective at a distance. Next to this the value of *Antholyza paniculata* appeared, the crimson-scarlet tubular flowers sheathing out from sword-like blades of healthiest green being most effective. It is not a novelty, of course, rather a neglected plant of more than ordinary merit. *Polygonum amplexicaule*, because of its distinctive Indian-red tone, should be freely grown; *Aconitum Fischeri* likewise, as representative of the most intense violet-blue member of this genus at this season. In addition to the above there were *Phloxes galore*, also Lilies and Gladioli. In a group from Mr. G. Reuthe the most striking item was *Polygonum amplexicaule atropurpureum*, a richly-coloured variety of a good plant. *Ardisia japonica*, whose pendent white flowers are succeeded by orange-coloured fruits, is among the gems for woodland work. *Gaultheria nummularifolia* aptly describes a rock-loving species of trailing habit, and distinct withal. *Dianantha cœrulea* is a novelty from Japan, having drooping violet-blue flowers with white anthers on a foot-high plant. *Bockia affinis*, seen by many for the first time, bears elegant sprays of white flowers not unlike *Spiraea arguta* in effect. Hardy Heaths were very beautiful. *Aster Amellus* King George is the finest addition to the Italian Starworts we know. Twice the size of the original, and rich violet-blue in colour, an outsider can readily estimate the value of the newcomer. It was well shown by Mr. W. Wells, jun., who also had the sky-blue *Delphinium Belladonna plenum*, the pale blue *D. Merstham Glory*, and *D. La France* (bluish-mauve), which, if not new, is too good to be out of any collection. In a group of hardy *Fuchsias* from Messrs. G. Bnyard and Co. the miniature-growing *Tom Thumb*—presumably a variety of *F. pumila*—forming a little hush of 8 inches high was loaded with flowers, and *F. Thompsoni*, of taller growth and very graceful habit, at once caught the eye.

ROSES.

Only one exhibit of these was on view, viz., that from Rev. J. H. Pemberton, who for some time has been raising new varieties of the cluster—*Polyantha*—or allied types, particularly in the yellow shades or approaches thereto. In addition to other good qualities they have the merit of perpetual flowering. *Dana* (H.T.) is one of the best yellows, good for autumn flowering. Even more distinct and far more popular is *Clytemnestra* (H.T.), which gained a Gold medal in 1914. It has coppery tints, the flowers opening salmon-chamois. The plant assumes a hushy habit of 3 feet to 4 feet high. The novelty of the moment, however, was *Callisto*, of pale and deep canary-yellow, against which its dark-coloured wood is in good contrast. It gained an Award of Merit.

FERNS.

The freely-tasselled, much-branched *Pteris tremula Smithi* stood out as one of the most distinct Ferns in a comprehensive exhibit of these from Messrs. H. B. May and Sons. With many of the good attributes of the type, it is of dwarfer habit and very ornamental. *Asplenium marginatum* is a rare and handsome species with broad, deeply-lobed fronds of yellow-green colour, which it is said no treatment will alter. *Polypodium glaucum crispum* is almost alone in its class, and a plant of fine ornament. The newest of the *Nephrolepis* is *N. gracillima*, densely plumose and quite dwarf.

DAHLIAS.

The principal novelties came from Messrs. Stredwick and Sons, who showed *Bizarre* (Cactus), crimson, white tipped; *Alabaster*, large white (Cactus); *Mascot* (Collarette), purplish-magenta; *Saffron* (Cactus), of greenish-yellow tone; *Private E. Drury* (Collarette), terra-cotta and Salmon; and the *Pompon Cactus*, *Amethyst*, which is of magenta shade. Each received an Award of Merit. Messrs. J. Cheal and Sons showed a general collection of these flowers, the novelties including the pure white *Paony-flowered Aphrodite*, and *Leon* (single), of rich scarlet tone. *Northern Star*, *White Star*, and *Crawley Star* are a trio of a new and decorative class valuable for the garden for cutting.

ORCHIDS.

Lælio Cattleya Thyone, var. *Bryndir*, is a handsome hybrid, having a lip of rich orange-yellow with crimson border and yellow sepals. It came from Dr. Lacroze, Rochampton. Another novelty was *Lælio-Cattleya Golden Wren*. This has greenish-yellow sepals, canary-coloured petals, and golden-yellow lip richly bordered with ruby-crimson. Both gained Awards of Merit, the latter being shown by Messrs. Armstrong and Brown, whose lot included *Sophr-Cattleya Blacki* and *Cattleya Iris Majestic*, novelties of first importance. In a choice assortment from Messrs. Sander and Sons the pure white *Cattleya Lady Veitch*, var. *superba*, stood out from all. *Lælio-Cattleya Purple Emperor*, *L.-C. Queen Marie*, and *Brasso-Cattleya Mme. Charles Maron* (palest mauve with yellow throat) were other good things. *Lælio-Cattleya Appam* (reddish petals and ruby-crimson lip), from Messrs. Charlesworth, appeared at once, and among others, *L.-C. Thyone* and *Cattleya Lord Rothschild*. *Cattleya Sybil* and *C. Adula*, from Messrs. Hassall, displayed a remarkable colour range in golden, buff, and fawn.

FRUIT.

Mr. C. A. Cain, J.P., Welwyn, Herts (gardener, Mr. T. Pateman), sent a meritorious exhibit, for which a Gold medal was deservedly awarded. Of a comprehensive character, comprising upwards of sixty dishes, the collection contained many bunches of superbly-grown Grapes, as *Muscat of Alexandria*, *Appley Towers*, *Black Hamburg* (very fine), *Gros Maroc* (of superb quality), *Lady Downe's Seedling*, and *Lady Hutt*, among others. Peaches, Plums, Apricots, and other fruits were alike well shown. Mr. J. C. Allgrove showed two year old and three year old fruiting trees of the new Apple *Rev. W. Wilks*, the older examples carrying from nine to a dozen handsome fruits. The variety is obviously a great cropper. Of Plums, *Diamond*, *Gisborne's*, *Belle de Louvain* (handsome dark variety), and *Tbe Czar*, gathered fruits, were shown.

A complete list of the new plants certificated and medals for groups will be found in our advertisement columns.

THE WEEK'S WORK.

OPEN-AIR GARDENING.

IN BLOOM AUGUST 30TH.—*Desfontainca spinosa*, *Solanum jasminoides*, *Ceanothus* (in variety), *Wistarias*, *Buddleias* (in variety), *Polygonum baldschuanicum*, *Clematis* (species and varieties), *Honeysuckles* (late-flowering varieties), *Jasmines*, *Hydrangeas*, *Spiræa Aitchisoni*, *Spartium junceum*, *Hypericum*, *Hardy Fuchsias* (in variety), *Rhus* (in variety), *Aloysia citriodora* (Sweet-scented *Verbena*), *Myrtus Luma*, *Andromeda polifolia*, *Clerodendron trichotomum*, *Indigofera Gerardiana*, *Sambucus canadensis*, *Daphnæ Cneorum*, *Romneya Coulteri*, *Desmodium penduliflorum*, *Cistus* (in variety), *Veronicas* (in great variety), *Nandina domestica*, *Yuccas*, *Olearia Haasti*, *Mertensias*, *Geums*, *Anchusas*, *Morina longifolia*, *Tritomas* (in variety), *Echinops*, *Eryngiums*, *Erigerons*, *Michaelmas Daisies*, *Delphiniums*, *Phloxes* (in variety), *Galgas*, *Anemone japonica* (in variety), *Chrysanthemum maximum* (in variety), *Statice* (in variety), *Helenium pumilum*, *Helianthus* (in variety), *Achilleas*, *Linums*, *Centaureas*, *Agrostemmas*, *Lobelia cardinalis* (in variety), *Cimicifuga racemosa*, *Campaulas* (in variety), *Bergamots*, *Platystemon*, *Montbretias* (in variety), *Gladiolus* (in variety), *Hyacinthus candicans*, *Liliums* (in variety), *Hollyhocks*, *Verbascums*, *Lavateras*, *Sidalceas*, *Pentstemons* (in great variety), *Astilbes* (in variety), *Epilobiums*, *Lythrum roseum*, *Lysimachias*, *Polygonums*, *Aponogeton*, *Nuphar*, *Flowering Rush*, *Water Lilies* (in variety), *Spiræas* (in variety), *Mimulus* (in variety), *Acrocliniums*, *Collinsias*, *Nemesias*, *Salpiglossis*, *Stocks* (in variety), *Clarkias*, *Godetias*, *Phlox Drummondii*, *Leptosiphons*, *Annual Delphiniums*, *Sweet Sultans*, *Antirrhinums* (in variety), *Cosmos*, *Calceolaria amplexicaulis*, *Cannas*, *Salvias*, *Scubious* (in variety), *Marguerites*, *Summer-flowering Chrysanthemums*, *Nigellas*, *Carnations* (in variety), *Audrosace lanuginosa*, *Veronica Lyalli*, *Pratia angulata*, *Plumbago Larpentæ*, *Gysophilas*, *Tunica Sari-frogo*, *Polygala Chamæbuxus purpurea*, *Dryas octopetala*, *Nicrembergia rivularis*, *Silene Schafta*, *Agopanthus umbellatus*, *Roses* (in variety), *Sweet Peas*.

WORK OF THE WEEK.—The chief work during the past week has been the propagation of such plants as *Calceolarias*, *Pentstemons*, *Phloxes*, *Mesembryanthemums*, etc. Frames were prepared by placing in them a bed of sandy soil about 6 inches deep. This is made moderately firm and the cuttings dibbled in 3 inches to 4 inches apart. The cuttings root readily and will remain in the frames throughout the winter. The frames are kept close until the cuttings are rooted, after which an abundance of air is given on all favourable occasions. *Lavender* flowers being over, the bushes have been trimmed with the hedge shears. A good batch of cuttings has been put in. Side shoots root readily at this season if put in on a warm and fairly dry border. Young stock should always be kept up, as I find *Lavender* is best when replanted every third or fourth year, even good-sized branches cut off and planted deeply in the soil will root freely and soon form good flowering plants. Early batches of *Sweet Peas* have been cleared. The later batches are blooming freely, and in order to assist them the old flowers are picked off and the plants kept moist at the roots. The layering of *Carnations* was carried out during the week. As soon as they are well rooted they will be potted up, placed in a cold frame for the winter, and planted out in early spring. Owing to the damp atmosphere in this locality, *Carnations* will not stand the winter planted out. In more favoured districts I strongly recommend autumn planting, in which case they should be layered early in August and planted in their permanent quarters in September. There is always a certain amount of work on the herbaceous border, and just now when many of the summer-flowering plants are going over, there is much to do in the way of cutting down and making tidy.

F. W. GALLOP.

Lilford Hall, Oundle, Northants.

SOUTHERN COUNTIES.

Black Hamburgh Grapes.—Those intended for late supply must receive every encouragement to swell to their fullest size, and as soon as colouring is general, make the most of the warm weather to bring about a good finish. Attend to the frequent stopping of laterals, but at the same time take advantage of such growths being present to cover any bare spaces there may be on the trellis, as the Black Hamburgh quickly loses colour if exposed to much sunlight. In regard to this matter it is often necessary to shade the roof after the Grapes have finished when the weather is bright and sunny, as is often the case in the latter part of September and during October. If the roots are in an outside border the latter should be protected with shutters or corrugated sheet iron as soon as the finishing stage is reached to prevent the soil becoming saturated should rainy weather set in. The inside of theinery must be kept cool and as dry as possible, and if it contains any plants, these for the time being should be taken elsewhere. This will avert all risk of losing berries from damp. In foggy and wet weather the ventilators are best kept closed, and when it clears up open them to their fullest extent, and if the outside air is chilly turn on enough fire heat to warm the pipes.

Strawberries.—If it was found impossible to layer into pots the requisite number of runners with which to form new beds, or where this has been done to prepare the sites intended for them in a proper manner, steps should be taken in the first instance to lift the required number of runners which will now be found firmly rooted between the rows of old plants, and to plant them in rows 9 inches apart and 1 foot asunder, on a border or any spare piece of ground. If lifted with balls of soil and well watered as soon as planted they can be lifted in splendid condition next February or March, and will give an excellent account of themselves the following season. Between now and then an opportunity will present itself to well manure and deeply dig the sites intended for them. Although a crop of fruit must not be expected till the following season the ground need not lie idle, as if the rows of plants stand from 2 feet to 2½ feet apart, Lettuces, Spinach, Horn Carrots, Radishes, or anything that will turn in quickly may be grown between them. Where the plants are already in pots they should be planted out in nursery rows as above as quickly as possible to prevent them getting further pot-bound. If got out early after the turn of the year these will yield a crop of fruit next season, but not sufficient in quantity to warrant the leaving of the ground between the rows uncropped unless there is plenty of space at command.

Hardy fruits.—Morello Cherries are now in the right condition either for bottling in the usual way or for preserving. Plums and Gages for bottling must be gathered before they become too ripe, otherwise the fruits will not remain in a whole condition after being subjected to heat. Peaches and Nectarines, particularly early varieties on walls facing south, will now require a look over every other day, if not daily. It is a mistake to allow them to become too ripe. If caught in the right condition and placed in the fruit-room they finish up there to perfection.

Fruit-room.—Before this is likely to be required for the general storage of fruit any necessary repairs or alterations should be carried out and the structure carefully cleansed, finishing by giving the ceiling and walls a good lime-washing. This is a matter that cannot be over-estimated where brown-rot fungus was rife last year.

Vegetable Marrows.—That the plants may continue bearing as long as possible every fruit should be cut directly it is large enough for use. Allowing them to become over-large or to go to seed has an exhausting effect on the plants and quickly leads to their becoming non-productive. In dry weather water should be given regularly at the roots.

Scarlet Runners.—These have had a trying time of late where deep digging, mulching, watering, etc., have not been attended to, and tough, stringy pods, such as have been much in evidence in shop-windows lately, are

the result. It is not yet too late to remedy matters in this direction, and, in addition to keeping the roots well supplied with water, a mulch laid on on either side of the rows, if only of rough Grass cut from the hedgerows will keep them cool and prevent the soil drying out so quickly. Gathering should have regular attention so that there may never be any likelihood of any pods going to seed.

Lettuces and Endive.—A final sowing of both should now be made, and in the former case the drills should be drawn on a piece of fairly dry ground, as most of the plants will remain in them during the winter. The seed may also be sown broadcast on a border, but, all things considered, the former method is the more convenient.

Onions.—Every attention should be paid the spring-sown plants in the way of keeping the tops bent over to favour bulb development, and the ground clear of weeds so that they may become fully matured ere cold weather sets in.

Mignonette.—A sowing in 3-inch and 4-inch pots should take place now to furnish plants to bloom in winter and spring next. A compost of two-thirds loam, one-third leaf-mould or well-decayed manure, and a liberal quantity of sand with a little fine lime rubble suit Mignonette. Fill the pots to within three quarters of an inch of the rims, sow the seed thinly, and cover lightly with fine soil. Place in a cold-frame, and when the plants are large enough thin out to five of the best in each pot. A shift into 6-inch and 7-inch pots should be given as soon as the plants have four or five fully developed leaves and are well rooted.

A. W.

MIDLAND COUNTIES.

Peaches and Nectarines.—Many complaints are annually heard of Peach and Nectarine trees under glass dropping the greater portion of their blossoms in the spring. In most cases this is due to extreme poverty or dryness at the roots during the autumn and early winter, or else very loose borders. After all the fruit has been gathered the borders should be cleared of the mulching, the surface lightly broken up with a fork and given a good soaking of diluted farmyard liquid-manure. Failing this, clear water may be given. Grape Vines and Fig-trees, also, should never be allowed to become dry at the roots, as a few days' neglect in this respect may endanger the next year's crop. Not only should they be kept regularly supplied with water, in order to secure a perfect formation of buds, but they should also be given, if possible, liberal supplies of liquid-manure, thus assisting the Vines or trees to recoup their strength after the exhaustive maturation of their crops.

Raspberries.—All the old bearing canes have been cut out, and the young ones sufficiently thinned, care being taken not to damage the foliage of those retained for next year's fruiting. This operation will admit of more air and sunlight amongst the selected canes, with the result that they will be better ripened. For this reason they should not be tied closely to the trellis until the foliage has fallen, but merely loosely secured to prevent injury by wind. If liquid-manure is available, a good soaking of this will at this season be beneficial, particularly to old plantations that are declining in vigour. Autumn-fruiting kinds should have their fruiting canes exposed as much as possible to the sun and kept well thinned, otherwise the fruit will not ripen satisfactorily.

Strawberry runners may still be planted, but unless they are extra strong they must not be expected to produce much fruit next season. Strawberries planted early have a better chance of becoming established and of ripening their crowns before frost arrives.

Cinerarias.—The early batch is now ready for transferring to their final pots—6-inch or 7-inch, according to the strength of the plants. A suitable compost consists of three parts good fibrous loam and one part leaf-mould, adding coarse sand, decayed cow-manure, and a sprinkling of fine bones and soot. The potting should be firmly done and the plants replaced in the cold-frame in a cool, shady position. A

little soot should be sprinkled over the ashes in the frame under the pots to destroy any slugs which may be present. Examine the foliage of the plants, and if any signs of maggot are found the insects should be searched for and destroyed, removing and burning any badly infested leaves. As a preventive of this pest I spray the plants occasionally with Quassia extract, taking care that the under part of the foliage is also wetted. Ventilation should be gradually increased as the plants develop, and, finally, if the weather is warm enough, the lights may be left off throughout the night.

Carrots.—The main crop of this vegetable will be lifted and stored as soon as possible. Care must be taken not to place the roots in too large a heap or they will become heated and damaged. Late sowings are thinned sufficiently to prevent overcrowding. As small Carrots are always acceptable, the plants are thinned as required for use.

Beetroot should not be left in the ground after the roots have reached their full size, or they will become coarse and unfit for use. The roots should be stored in a cool, dry shed, placing sand amongst them in sufficient quantity to exclude the light and keep them moist.

The Potato crop appears very promising in this district, disease, so far, not having affected it seriously. Mid-season varieties will now be lifted, for should cold, showery weather set in, a large percentage of the tubers may become diseased. Choose fine weather for the lifting, and where the facilities exist place the tubers in sheds, and then carefully examine them for diseased tubers before placing them in clamps for the winter. If freshly-slaked lime is lightly sprinkled over them it will dry up any affected tubers that may be overlooked. It also acts as a general sweetener and improves the flavour. Straw or dry Fern should be placed carefully over the tubers previous to covering them with a 9-inch layer of soil, which will be sufficient protection until frosts occur.

Turnips for the winter are now ready for thinning. A space of 9 inches is left between each plant, frequent light dressings of soot being afforded and the surface of the soil between the rows stirred as frequently as circumstances permit.

French Beans.—Plants from seed sown in cold pits early in August are growing strongly and require plenty of water at the roots. Frequent light dustings of soot keep red-spider and other pests in check. F. W. G.

SCOTLAND.

Vegetable garden.—Present sowings should include Cauliflowers for spring planting. In a general way the seedlings are pricked off into cold-frames in which they remain over the winter, although I have seen plants pricked out at the foot of a south wall and protected during frosty weather with Spruce branches, turning out much superior to those wintered in a frame. In the latter case damp is always present to a certain extent; and, further, in a mild winter growth is always on the move, with the result that the plants are often too large and too soft to be of much use when planted out. In many places autumn sowing is now dispensed with, and reliance placed upon young stuff raised in heat from sowings made about the New Year. Still, a few plants in frames are always useful if the season is favourable, and a sowing made in the last days of August or early in September can be relied upon to provide plenty of seedlings in time for pricking off before the nights get cold. Every grower has his favourite sorts. I like Early Erfurt, with Eclipse and Autumn Giant for succession. Early London is a good Cauliflower, so, too, is Walcheren, but a good strain of these seems nowadays very difficult to get hold of. Further lines of Carrots of the Horn type may now be sown in frames. Shallots now ripe, if not already pulled, should be harvested without delay, and spread out thinly until the bunches are thoroughly ripened. In the event of any scarcity of this bulb, if a few of the ripest cloves be selected and replanted immediately, quite a useful second crop may be lifted

toward the end of October. The Cloves from this planting, however, will not keep very well, so it is as well to use these first. It grows late for Lettuce sowing; but a pinch of seed sown in rich soil with a good exposure may give some fairly good heads late in the season. I have found nothing better this year than Henderson's New York Lettuce among the Cabbage varieties. Good in colour, and moderate in size, with beautifully crisped foliage, this variety does not bolt for a long time. A supplementary sowing of autumn Onions can now be made. These will do quite well on the quarter vacated by Potatoes. Spinach, the prickly variety, will also succeed now in a similar place, and with the cooler weather and the recent rains ought to be satisfactory. Take advantage of the moist state of the soil to thin out Spinach Beet, as the more room allotted to individual plants, the more robust will the leaves be. Seedlings of this useful substitute, it may be mentioned, transplant readily. Keep the hoe at work among breadths of winter vegetables. Before hoeing, a dressing of guano or other stimulant—even soot, if nothing else is available—will benefit the plants. Any superfluous French Beans ought to be picked at close intervals and salted down for winter use. We generally grow a line or two especially for this purpose, but when the supply from other lines is in excess of the demand the surplus is preserved. Nothing is gained by permitting spent lines of Peas to remain on the ground. The same observations apply to Broad Beans. Second-early Potatoes, if grown to any extent, may now be lifted and stored. If, however, these are not largely cultivated, it is just as well to allow them to remain in the soil until they are required. Before earthing up Celery a good drenching of water or, better still, liquid-manure ought to be given.

Lavender.—An excellent crop of this favourite flower was harvested in the course of the week. The particular bed from which the spikes were cut is now in its third season, and with a little attention may be depended upon to last for some seasons yet. Where it is intended to renew or to increase the supply, cuttings ought to be taken early in September. Opinions differ as to the best method to pursue. I treat Lavender cuttings in all respects like those of the bedding Pelargoniums, even to the extent of keeping them in heated pits over winter and spring. The advantage thus gained is never lost, the plants when hardened off and put out in spring go away rapidly and flower in a moderately free way during the following summer.

Stove.—If it is necessary for any reason to cleanse this house before winter sets in an opportunity should be made for doing so without delay. At this time the plants usually associated with the stove will not suffer if removed for a short time to another house, and the sweetening up of walls, woodwork, and glass will go far towards success in the dull winter months. Among some plants this is the time of resting or of ripening, so that as much air as possible ought to be given on all suitable occasions. Any good Gloxinias may now be increased from leaf cuttings. These, inserted in the propagating pit, kept shaded, and moderately moist, will soon callus and form firm little bulbs which will be useful early next year. Similarly, leaves of Saintpaulia ionantha will soon develop into neat little tufts, which are of value in 3-inch or 4-inch pots. Gesneras for early-winter blooming are already showing the central flower-stalk. These are being pinched out as they are noticed with a view to inducing a freer break of side shoots. It is intended to use a proportion of these plants for greenhouse purposes, some which were so grown last season being equally as good as those in the stove, although, naturally, later in coming into flower.

Melons in pits have been top-dressed during the week. As the ripening stage approaches less water will be given and a chink of air left on during the night. Owing to the lack of sun in the early part of the season, the crop will be a little later than usual although, on the whole, more satisfactory than in the case in 1915.

W. McGUFFOG.

Balmac Gardens, Kirkcudbright.

CORRESPONDENCE.

Questions.—*Queries and answers are inserted in GARDENING free of charge if correspondents follow these rules: All communications should be clearly written on one side of the paper only, and addressed to the EDITOR of GARDENING, 63, Lincoln's Inn Fields, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent each should be on a separate piece of paper, the name and address being added to each. As GARDENING has to be sent to press some days in advance of date, queries cannot always be replied to in the issue immediately following their receipt. We do not reply to queries by post.*

Naming plants.—*All who wish their plants to be rightly named should send fair examples of each—the stem, leaf, flower, or fruit. (Snippets of leaves and points of shoots are useless.) Not more than four plants should be sent in any one week by the same correspondent. Where more than one kind is sent they should be numbered. Of conifers the fruit should always be sent.*

Naming fruit.—*Several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruits for naming, these in many cases being unripe and otherwise poor. We can undertake to name only four varieties at a time.*

PLANTS AND FLOWERS.

Unhealthy Gloxinias (W. B.).—The leaves are badly affected with "thrips," a great insect pest to Gloxinias, and generally brought about by a hot, dry atmosphere in the house, and sometimes also the plants may have been allowed to get dry at the roots. The only thing to do now is to maintain a cool, moist atmosphere around the plants, and to give very frequent light fumigations with Tobacco. These must be often repeated, or the "thrips" will not be destroyed.

Lavender, cutting down (Lavender).—We should advise you to put in a lot of cuttings at once under a handglass, if you have such; if not, in the open under a shady wall. Cut down the plants next March, and put a layer of manure over the roots, keeping them well watered if the weather is dry. The old plants should break from the bottom and become thick and strong. If they fail to do so dig them up and well manure and till the ground, and plant the cuttings which have been struck and will be well rooted.

Hydrangeas, blue (Bournea).—There is always a great amount of uncertainty about obtaining flowers of the right colour, even when, as far as our knowledge goes, we adopt what is considered the best means to secure the object in view. The following compost for plants in pots has been recommended:—One half should be turfy loam (broken up with the hands and not sifted), the other half a mixture of peat, crushed charcoal, and about 2 lb. to the bushel of iron filings. It is generally supposed that the blue colour is due to soil which contains iron. Kindly send a few leaves of the Primulas you refer to, and tell us something of how you are growing them.

Asparagus plumosus nanus (G. Penwell).—Since the introduction of this useful plant its cultivation has gradually extended, and at the present time some growers have it by the thousand. It is chiefly grown for cutting, the flat, feather-like branches being very useful for almost all kinds of floral arrangements. Among florists it is frequently called Asparagus Fern. It is now a greater favourite than *A. plumosus*, and can be easily increased from seed, which can be had when the plants become established. This Asparagus is generally treated as a stove plant, and where kept free from insects it does well in a high temperature. It will do equally well in a cooler atmosphere, and is not so liable to the attacks of red-spider, which is one of its greatest enemies. To grow it successfully the chief point is to give it plenty of root room and good drainage. Any ordinary potting com-

post may be used, but a light fibrous loam is preferable. To this may be added leaf-mould and some well-rotted manure, or some peat may be used if the loam is heavy. Where required for cutting, planting out is the best system; under favourable conditions a few plants will give a regular succession of useful material. The plants should never be cut in too hard, but to secure good-sized branches the old stems should be thinned out occasionally. Where the plants are strong and healthy they require a good deal of water and will suffer if allowed to get dry. Full exposure to the light is necessary.

Carnations from cuttings (Patch, Dublin).—The only really quick and certain way of treating cuttings in the open is as follows:—From any large tuft that contains many growths that could not be layered in time, let anyone take and strip off from the parent plant, each with a heel attached, as many pieces as are required. Taking the growth in the thumb and fore-finger of the right hand, and giving a slight, yet sharp, downward pull, the piece will come away with a perfect heel almost every time. Now make a little trench as though setting a Box edging, and so deep as to admit the so-called cuttings being buried up to the leafy tuft, and insert them without trimming, stem-splitting, or stone wedges. A little pure sand or very sandy soil may be put into each trench at option, all depending on the nature of the soil. There is, however, no need for any prepared bed of soil at all. As the cuttings are placed in the trench, and while held in position by the left hand, draw sufficient soil with the right hand to keep them fairly erect, and, finally, finish off with the spade while also preparing a second trench. A good gentle tread with the foot when the trench is two-thirds filled with soil is a necessity. Not only is this a quick way, but a way that ensures cuttings of the size of layers, and quite large enough for spring planting. You may put in the cuttings of Rambler Roses at any time during the autumn, selecting the firm and well-ripened wood. When sending queries, please put each on a separate slip of paper.

FRUIT.

Mildew on Vines (H. G. T.).—The causes of mildew are often very difficult to trace. Mildew may be caused by cold, damp, sunless weather, with a stagnant atmosphere, especially if bright sunshine follows this. Again, it may be due to cold draughts of air allowed to play over the foliage. One of the surest preventives is plenty of fresh air, which can be had by attending to the ventilation and keeping the air warm and buoyant by using the hot-water pipes. If the house is a cold one, then keep it dry during cold, damp weather, and do not syringe or damp down. Sulphur sprinkled on the foliage is the best remedy, or, if the house is heated, paint the pipes with flowers of sulphur mixed with milk, the fumes arising from the heated pipes being destructive to the mildew.

VEGETABLES.

Cutting and drying Herbs (An Old Subscriber).—Mostly all herbs should be cut and dried before the middle or end of September, not so much for the sake of the herbs to be dried as for the roots left in the ground. There are many kinds of herbs, such as Mint, Sage, Thyme, etc., which perish during winter if they are not cut in time to allow the plants to make short growth before the growing season comes to an end. Herbs must not be dried, as some do, before a kitchen fire. Those who buy bottled Parsley and such like should smell it first. The best way to dry herbs is to spread them out in a dry, airy room or loft, turning them over frequently to prevent the leaves getting mouldy. In damp, dull weather a dry vinery or Peach-house is a good place, hanging the bundles over the wires. The object in all cases should be to dry them gradually, and the leaves should retain their colour to a considerable extent and adhere firmly to the branch. When they crumple up in the hand, they have been subjected too much to the kitchen fire process, which destroys their virtue. After being thoroughly dried, hang them up in a dry shed. We doubt very much if small growers could find a sale for herbs.

SHORT REPLIES.

W. Oliver Grindley.—The plant you are growing is what is called wrongly the "Jerusalem Artichoke" (*Helianthus tuberosus*), a Sunflower, and whose tubers are eaten, the other being known as the true Artichoke (*Cynara Scolymus*), the base of the scales of the flowers of which, and also the bottom of the Artichoke, are eaten either cooked or raw. Cookery recipes, too, are muddled by the error of giving the same name to wholly different plants.—*Agnes Unwin.*—No; cutting off the dead flowers will do no harm in either case.—*Clanswoman.*—Yes; there are various trustworthy English firms which can supply what you require. Of course, you are aware that no Hyacinths or early single and double flowering Tulips can be had from our seedmen, but in this country we have a sufficient variety of other bulbs to meet all requirements.—*W. M. Crowfoot.*—The name Rose Apple has been given to the species of *Eugenia*.—*Mrs. Nicholson.*—The best plan would be to leave the cutting back till the spring, as, should we have a severe winter, the plants would probably suffer. Yes; the Lavender is best pruned back immediately after the flowers have been gathered.—*Tom.*—1, Yes, the border you refer to will do well for Gooseberries, Red, and Black Currants. In such they will come in late and be very useful. 2, Dig in the manure at once in order to prevent any loss of its fertilising value.

NAMES OF PLANTS AND FRUITS.

Names of plants.—*Amateur.*—The Fire Thorn (*Crataegus Pyracantha*). To protect the berries from the birds the only thing you can do is to cover them with a net.—*B.*—1, *Elecampane* (*Inula Helenium*); 2, *Phacelia campanularia*; 3, *Alstroemeria aurantiaca*; 4, *Hypericum oblongifolium*.—*Y. B.*—1, *Blue Cupidone* (*Catananche cerulea*); 2, *Oenothera fruticosa*; 3, *Campanula pusilla alba*; 4, *Helenium autumnale*.—*C. R.*—1, *Rudbeckia Newmanii*; 2, *Solidago Virgaurea*; 3, *Aster*

Amellus; 4, *Astrantia major*.—*A. S.*—1, *Campanula lactiflora*; 2, *Centranthus ruber*; 3, *Erigeron speciosus*; 4, *Aster Thomsoni*.—*F. M. W.*—1, *Gentiana asclepiadea*; 2, *Plume Poppy* (*Bocconia cordata*); 3, *Galega officinalis alba*; 4, *Lysimachia clethroides*.—*G. A. S.*—1, *Diplacus glutinosus*; 2, *Tradescantia virginiana*; 3, *Sedum spectabile*; 4, *Scabiosa caucasica*.—*A.*—1, *Linaria reticulata aureo-purpurea*; 2, *Sedum album*; 3, *Echinops Ritro*; 4, *Thalictrum adiantifolium*.—*Leeds.*—1, *Harpalum rigidum*; 2, *Veronica Andersoni*; 3, *Lysimachia clethroides*; 4, *Veratrum nigrum*.—*J. C. C., Devon.*—1, *Abutilon Thompsoni*; 2, *Begonia metallica*; 3, *Sedum carneum variegatum*; 4, *Polygonum baldschuanicum*.—*M. C. G.*—1, *Sedum spurium*; 2, *Dianthus sp.*; 3 and 4, *Aubrietias*. It is quite impossible to name your plants with any degree of certainty from the dried-up specimens in the case of Nos. 2, 3, and 4 you send us.

Names of fruits.—*H. Gillott.*—1, Specimens insufficient; 2, *Margaret*, so far as we can say from the poor specimens you send us.—*W. B.*—Apples: 1, *Devonshire Quarrenden*; 2, *Lord Suffield*; 3, *Worcester Pearmain*; 4, *Jacob's Seedling*.—*W. W.*—Apples: 1, *Margaret*; 2, *Keswick Codlin*; 3, *Mank's Codlin*; 4, *Duchess of Oldenburg*.

LIST OF AWARDS AT THE R.H.S. MEETING ON AUGUST 29, 1916.

ORCHID COMMITTEE.
Awards of Merit.

Laelio-Cattleya Thyrone, var. *Bryndir*, from Dr. M. Lacroix, Roehampton; *Laelio-Cattleya Golden Wren*, from Messrs. Armstrong and Brown, Tunbridge Wells.

Medals.

SILVER FLORA.—Messrs. Charlesworth and Co., Haywards Heath; Messrs. Armstrong and Brown.
SILVER BANKSIAN.—Messrs. Hassall and Co., Southgate, N.; Messrs. Sander and Son, St. Albans.

FLORAL COMMITTEE.
Awards of Merit.

Rose Callisto, from Rev. J. H. Pemberton, Havering-atte-Bower, Romford; *Montbretia Queen of Spain*, from Mr. S. Morris, Earham Hall, Norwich; *Dahlia (Cactus) Bizarre*; *Dahlia (Collarette) Mascot*; *Dahlia (Cactus) Alabaster*; *Dahlia (Cactus) Saffron*; *Dahlia (Collarette) Pte. E. Drury*; *Dahlia (Cactus) Amethyst*. These Dahlias, all of which were shown by Messrs. Stredwick and Son, St. Leonards, were also given the First-class Certificate of the National Dahlia Society.

Medals.

SILVER GILT FLORA.—Mr. J. Box, Lindfield, for hardy plants.
SILVER FLORA.—Messrs. H. B. May and Sons, Edmonton, for Ferns, etc.; Mr. G. W. Miller, Wisbech, for hardy plants.
BRONZE FLORA.—Rev. J. H. Pemberton, for Roses; Mr. G. Reuthe, Keston, for hardy plants; Mr. W. Wells, Jr., Merstham, for hardy flowers.
BRONZE BANKSIAN.—Messrs. Cheal and Son, Crawley, for Dahlias.

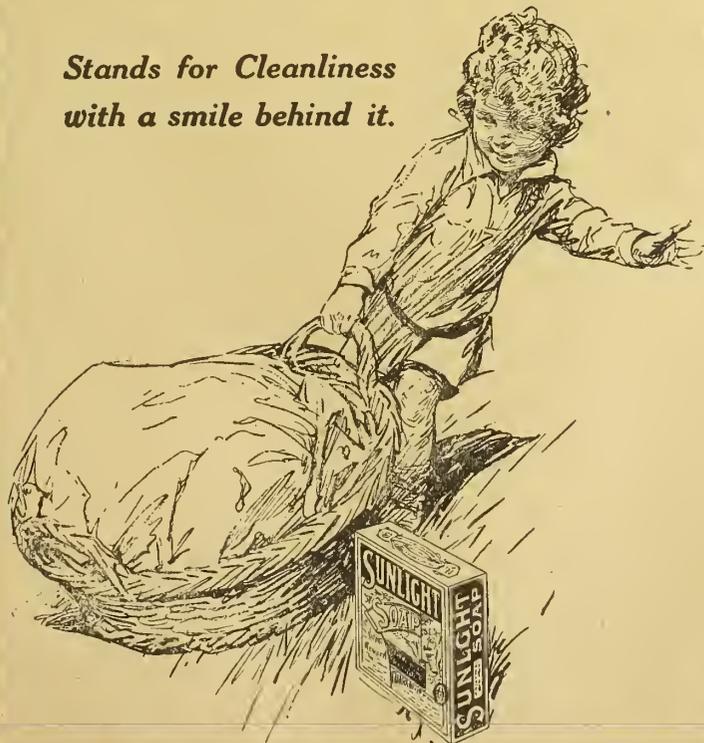

FRUIT COMMITTEE.
Medals.

GOLD.—Mr. C. A. Cain, The Node, Codicote, Welwyn (Gr., Mr. T. Pateman), for collection of fruit.
SILVER KNIGHTIAN.—Mr. J. C. Allgrove, Laugley, Slough, for collection of fruit.

SUNLIGHT SOAP

Stands for Cleanliness with a smile behind it.

PURITY is behind Sunlight Soap in the making. That is why, in use, Sunlight Soap ensures cleanliness with a smile behind it. The power to provide joyful cleanliness is behind every bar of Sunlight Soap. That power is purity.

Cleanliness means purification, and without pure soap you can't have perfect cleanliness. That stands to reason. Clothes worn next to the skin should always be washed with pure soap.

Clothes worn by little children should always be washed with the soap which has a big guarantee of purity behind it.

£1,000 GUARANTEE OF PURITY ON EVERY BAR.

Include a Tablet in your next parcel to the Front.

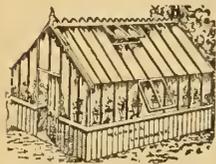

The name Lever on Soap is a Guarantee of Purity and Excellence.

NOTES OF THE WEEK.

Nemesia Orange Prince.—A new variety bearing this name and exhibited by Messrs. Dobbie and Co. in July last, when it gained an Award of Merit, is the largest and most brilliant of its shade that has yet appeared. The habit of the variety, too, gave the impression of increased vigour, a desirable quality not possessed by all the members of this race.

Crinum capense.—This does well with me in a warm border against a south wall, planted deeply in rich soil, and is now throwing up its spikes of handsome pink blossoms. It needs very little care beyond seeing that it does not get too dry in summer, and rapidly increases. In a severe winter it is best to put a mulch of leaves or ashes over it, but if planted deeply it will come through any ordinary winter without protection.—NORTH LONDON.

Gypsophila ortegioides.—This is a pretty species from Asia Minor, whose acquaintance I made for the first time recently in the Kew rock garden. A foot-high plant as seen, bushy, slightly woody or wiry of stem at the base, and smothered with tiny flowers of the purest white, it appealed to me. Having the reputation of being a good perennial, breaking afresh from the soil each year, after the manner of some Linums, hardness and neatness—good attributes—are assured.—E. H. J.

Aconitum Napellus album grandiflorum.—The white variety of the common Monkshood has never impressed us, hence the coming of this much-improved form should be welcome. Of a decidedly purer white, so far as the individual flowers are concerned, the much taller growth and pyramid-like panicle of blossoms render it quite distinct. The effect should be good when grouped amid suitable surroundings. It was shown by Messrs. Barr recently and gained an Award of Merit.

Campanula White Star.—This is a carpatica form raised ten or a dozen years ago, I believe by Mr. M. Prichard, and which, by reason of vigour, free flowering, and distinctness should be in every garden. Nine inches or so high, the handsome, pure white flowers are salver-shaped, and in the largest examples each nearly 2 inches across. From mid-June till August it is quite among the indispensables of its race, admirably adapted to grouping in the border or the rock garden. It is of the easiest culture in a cool, loamy soil.—E. H. J.

Hardy flowers in railway station gardens.—In most of the best railway station gardens in Scotland this year herbaceous plants appear to be in the ascendancy, and they certainly have proved the most valuable, especially when some good hardy annuals are employed to fill up the gaps caused by the decay of the leaves of early-flowering bulbs. There can be no comparison between these and some of the other beds filled with *Calceolarias*, *Lobelia*, *Zonal Pelargoniums*, *White Alysium*, etc.—S. ARNOTT.

Marguerite Carnations.—For many years I have grown these in the flower garden and also in pots for the supply of cut flowers. Good strains give a large percentage of double flowers, but I am very partial to the single ones. From seeds sown in a slight heat in February, flowering plants are available at the end of the summer and onwards throughout the winter if proper treatment be given. Some may be grown in pots, others in the open border and then lifted and potted in September. Till Christmas, plants in the open, temporarily protected, yield sheaves of blossom for cutting.—G. G. I.

Campanula arvatica.—I procured this from Sündermann in March, 1913, under the name of *acutangula*, and since then it has increased enormously. It has easily survived the last two winters in the open, both in rather heavy, limeless loam and in limestone chips. It grows luxuriantly in the former, but is not quite so happy in the latter. It can be propagated by division with a trowel. Soil, climate, and situation are in general so adverse here that it is a wonder to me that what thrives here should prove difficult elsewhere, as E. H. Jenkins suggests (August 19th). Possibly, like some other *Campanulas*, it dislikes lime.—L. J. ROGERS, Leeds.

Campanula Chastity.—This, when shown by Messrs. Grove in mid-July, when it gained an Award of Merit, gave one the impression of a small pure white form of *C. carpatica*, which is also very free flowering. To some extent the purity of the flowers may have been due to cultivation under glass; the dwarfness of the plant—it was but 6 inches or so high—to youthfulness. It was so full of bloom, however, that it was generally admired, while the more established plants, even with the flowers less pure in colour, were most attractive. The flowers are somewhat more bell-shaped than in the white *C. carpatica*, and with their smaller size render the variety quite distinct.

Tiger Lilies in station gardens.—I have recently visited some of the best railway station gardens in the south-west of Scotland and have been struck with the use made in many of these of the Tiger Lilies. In several of these the variety appears to be *L. tigrinum superbum*, but in others the handsome *L. t. Fortunei* is employed. As a rule they are well grown, especially in gardens, for which a premium is offered by the railway companies.—S. ARNOTT.

Gypsophila paniculata fl.-pl.—This plant has been doing exceptionally well this year, as proved by some fine examples of it in the herbaceous border at Kew, where it has reached 4 feet or so high, forming a bush of mound-like character several feet through, and covered with innumerable pure white flowers. The effect of so large a group is much whiter than in the typical kind by reason of the increased spread of the far more numerous petals. Both are desirable, however, in the garden, and when established provide much material for associating with cut flowers. Frequent disturbance of old plants is not desirable, though young plants and seedlings transplant well.—E. J.

Gentiana ornata.—I post you a couple of blossoms of *Gentiana ornata*. Do not you think it is one of the loveliest plants you ever saw? The flowers are carried on prostrate stems, and they turn up and are carried erect. I find it does very well in a cool, rather moist, bed of peat, leaf-mould, and loam, and although it is very rare at present it is not a difficult plant to grow. I have another form of *Gentiana ornata* which flowers a little later, is a much stronger grower, and has larger flowers, and when it is out I will post you a few blossoms. Of this larger form I already have several hundred plants, but of the one I send to-day only three or four.—CLARENCE ELLIOTT.

Clematis Jouniana.—In some gardens this *Clematis* is grown as *C. grata*, under which name it was distributed a few years ago. *C. grata*, however, is a distinct plant, a species from China and the Himalaya, whilst *C. Jouniana* is of hybrid origin, its parents being *C. Vitalba*, the Virgin's-bower of our hedgerows, and the low-growing, blue, tubular-flowered *C. Davidiana*. *C. Jouniana* is of vigorous habit, growing at least 12 feet high, with large dark green leaves and very long inflorescences of white, violet-tinged flowers, the end of a shoot 2 feet or more long often appearing as a large panicle of

blossom. The flowering time is August and September, and at that period it is usually one of the most noticeable shrubs in bloom. It should be planted so that it can grow over a large bush or small tree. Failing that, a group of rough Oak branches forms a good substitute. Rich loamy soil should be provided and a little lime given as a top-dressing now and then is an advantage.—K.

Rose Gruss an Teplitz.—In a paragraph in GARDENING ILLUSTRATED, August 26th, 1916, I notice a remark that "on strong soils" it is "shy-blooming," especially if the knife is used "too freely," and I think that it may be interesting to record my experience with this Rose on a strong soil in the west of Scotland. I find it a very free-bloomer, and it has been most successful for many years past grown on a wire fence 2 feet high. It was pruned freely in the first week of April this year, having suffered much from frost in November, 1915, and having much dead and injured wood. It made splendid growth of new wood, began blooming June 24th, 1916, and is now (August 26th) covered with flowers. In 1915 it began flowering June 14th, and on October 16th it is recorded "good blooms." In 1907 it is recorded on November 8th "Gruss an Teplitz hedge, splendid sprays, very bright and effective."—R. S. CAMPBELL, *Achnashie, Rosneath.*

Campanula Vidali.—Of all the Bell-flowers this distinct species from the Azores is probably the most remarkable. Unfortunately it is not hardy, and to see it at its best it must be grown in the greenhouse. Quite recently a big group of it was in excellent condition in No. 4 greenhouse at Kew, where it had evidently been in bloom for some time. Distinct in its thick, fleshy, coarsely-toothed leaves, and almost tree-like stem, its flowers are unique, these being white, wax-like in character, pendulous, 2½ inches to 3 inches in length, much contracted about the middle, and somewhat expanded at the mouth. Internally they are characterised by the broad ring of bright orange, which encompassing the ovary, renders that part of the flower highly distinct. Raised from seeds it is by no means a difficult plant to grow. It is only rarely seen at exhibitions, this probably accounting for its being so little known. It received a first-class certificate over twenty years ago.—E. H. JENKINS.

The Mount Omi Rose (*Rosa omiensis*).—In 1901 seeds of this Rose were received in England by Messrs. Veitch from Mr. E. H. Wilson, who at that time was collecting for the firm in China. That it or one of its varieties may have been grown in England before under the name of *R. sericea* is probable, for the two species are closely allied, and as both vary in character there may be connecting links amongst the varieties. The Mount Omi Rose is a strong-growing bush 8 feet to 12 feet high, its relationship to *R. sericea* being very noticeable in the flowers, for both have four creamy-white petals instead of five petals as is usual in most of the Roses. The branches are closely beset with spines, which are often abnormally large, with wide-spreading bases. In some instances they are brightly coloured during the first summer, as in the variety *pteracantha* (also called *R. sericea pteracantha*). This is a very pleasing feature, but perhaps the plant is seen to the greatest advantage during late summer and early autumn, when covered with rich, orange-scarlet hips, each one about ¾ inch long and curiously narrowed at each end, making it somewhat barrel-shaped. Like other Roses, it gives the most satisfactory results when planted in good, deep, loamy soil. As a

rule the more vigorous the shoots the better the colour and the larger the spines, therefore it is advisable to treat it liberally when first planting it, and later by surface-dressing with well-decayed manure.—D.

Double Calendulas.—These were very late starting to bloom with me this year, but now they are in their full glory. Of all annuals for town gardens I think these are the best, for when in full bloom they are a regular sight. Of the several varieties it is hard to say which one likes the best, but the yellow sorts, such as Meteor or Sulphur Queen, are perhaps a little less showy than such sorts as grandiflora or Prince of Orange. The orange varieties often develop blooms of tremendous size, and the more blooms you cut the more you seem to get. They last well in water and are much appreciated by soldiers in our military hospitals. Calendulas are of very easy culture. They should be sown in a very sunny position in autumn or spring, or they may be sown in pots and planted out.—E. T. ELLIS, *Westwood, Ecclesall, Sheffield.*

Hollies losing leaves.—I have in my grounds a large number of Hollies of sorts (principally *maderensis*) and of various ages and growths. During the present summer most of them have been casting their leaves, and the adjoining ground and borders are always covered with dead leaves. I am aware that Hollies cast their leaves when growth of fresh leaves is taking place, but this is usually at the commencement of summer. Are you aware of anything to which their recent behaviour may be attributed? The soil in which they are growing is of a light, sandy nature, but some of the bushes are 40 years old and have always before appeared fairly healthy.—SUBSCRIBER.

[It is just possible that dryness at the roots may be the cause of the leaves falling. This you could ascertain, and if such is the case then it would be well if you would give the trees a thorough soaking of water, and, if possible, mulch them for some distance round the stems with well-rotted manure. We should have no fear of the trees coming right, in due course if there is nothing detrimental in the soil.—Ed.]

The Macartney Rose (*Rosa bracteata*).—The large number of garden Roses available for general use has done much to crowd out the single-flowered species from our gardens, although many of them are very beautiful when in bloom, while some are well worth growing for the sake of their attractive fruit. The Macartney Rose is a case in point, for it is lovely when covered with lustrous dark green leaves and handsome white blossoms. The fruits, however, in this case have no special recommendation. It is a native of China and has been known here since 1793, in which year it was introduced by Lord Macartney. Amongst other Roses it may be distinguished by its rather dense branch system, greyish bark of the young wood, its deep green, glossy, evergreen leaves, and its large white flowers, each 3 inches to 4 inches across, with a central mass of golden stamens, which are produced singly from the points of short shoots from early July until October. Unfortunately, it is not very hardy, and except in the mildest parts of the country requires a wall. If, however, it can be placed in such a position that it can develop naturally, the effect is much in advance of that of plants that are severely pruned each year. When in bloom not only does it attract attention by the beauty of its flowers, but its presence can be detected from a considerable distance by its perfume.—D.

FRUIT.

PLANTING STRAWBERRIES.

I AM going to make a bed of Strawberries. Will you kindly let me know the distance I should keep them apart, and what would be the best manure and soil to plant them in?—W. G.

[For growing Strawberries it is always best to choose soil that is inclined to be heavy than otherwise, but it should be well drained. Light soils may be made more suitable for Strawberry growing by the addition of loam of a heavy texture or road sidings. This should be well dug in and thoroughly incorporated with the staple. Such a dressing is better than applying quantities of manure. Heavy soils, on the other hand, are greatly benefited by being well manured, and the manure should be thoroughly decomposed. In choosing a site for a Strawberry plantation ignore low, damp situations, for although the Strawberries may succeed in a dry season, they would in a wet time fall a prey to mildew, and the fruit would rot. The digging done, matters may be left alone until the plants are ready for setting out, and then the soil should be made quite firm by trampling it evenly all over previous to planting. This will make a good firm bed for the plants to root into, and it will also in a great measure prevent the plants being thrown out or lifted by frost during the winter months. Some few hours before planting, the young plants should be well watered, and it is also a good plan to water them home directly the planting is completed. A trowel should be employed for setting out pot plants and pegged-down runners, and the soil must be made very firm about them. On light soils a mulch of spent Mushroom-manure or suchlike material spread round about the fresh set-out plants is of great assistance in preventing them drying quickly and needing so much water. On heavy soils, which naturally retain more moisture, mulching is not so essential. The usual distance for planting Strawberries is 2 feet between the rows in gardens and 3 feet for field culture, and the plants may be set out 18 inches apart. If planted closer than this every other plant would have to be lifted the second season.]

CANKER IN MELONS.

REPLY TO "GROWER."

As a rule, canker does not show itself before the plant is carrying fruit, and the cultivator may not be aware of its presence until after a somewhat lengthened spell of dull weather. The sun suddenly bursts forth, causing a total collapse of the plant and consequent loss of the crop. Canker in Melons is not always due to the same cause any more than is shanking in Grapes, but one of its most fertile sources, especially in early houses insufficiently heated, is a too low night temperature combined with a stagnant atmosphere, strong, rank growth also being more susceptible to the malady than that which is opposite in character. Careless ventilating, by which large volumes of cold air are admitted suddenly, the application of too cold water to the roots, allowing the same to come into contact with the base of the stems, excessive overhead syringings, especially on dull, sunless afternoons, and a consequent wet foliage at nightfall, are all frequent causes, either directly or indirectly, of this most virulent disease. In order to guard against it, Melon-seed should always be sown in loam pure and simple, and firm potting should always be practised. Water should never be applied to the roots at a lower temperature than 80 degs., and as these tropical subjects are

not so partial to the syringe as many people seem to imagine, its use should not be indulged in, save only in the finest weather, and even then in strict moderation. In planting, the mounds or ridges of soil should be made quite firm, and the collars of the plants be well elevated above the level of the soil. If the plants are in fairly close proximity to the hot-water pipes so much the better, as the heat from these disperses all superfluous moisture, and so prevents it from settling at the base of the stem. Surrounding the stems with a pliable piece of zinc or tin, and filling in the intervening space with small pieces of charcoal, is also a good preventive. No stimulant should be given till the crop tells upon the vitality of the plant, after which gross growth need not be apprehended. The growths which start from the base of the leaves between the ground and the trellis should not be stopped back too closely, especially if the plants are strong, and pinching with the finger and thumb is preferable to the use of the knife, as, the pores of the wounds being thereby closed, air is excluded, and cankerous attacks warded off.

TREES AND SHRUBS.

GROUPING TREES AND SHRUBS.

THE illustration shows a group of various trees and shrubs in an Irish garden. In the left forefront has been placed a New Zealand Flax, and to the centre and right a collection of various Hydrangeas, which always thrive the better when protected from winds, and at the same time serve to break the straight line of the Yew hedge behind. On the extreme right is a Scotch Fir with Birches beyond, the lower branches of the Fir having been removed in order to emphasise the white stems. In the middle distance is a large group of Ribes atrosanguineum, the blood-red form of the wild Currant, while between the latter and the Birches may be seen a group of Escallonia macrantha.

R. H. BEAMISH.

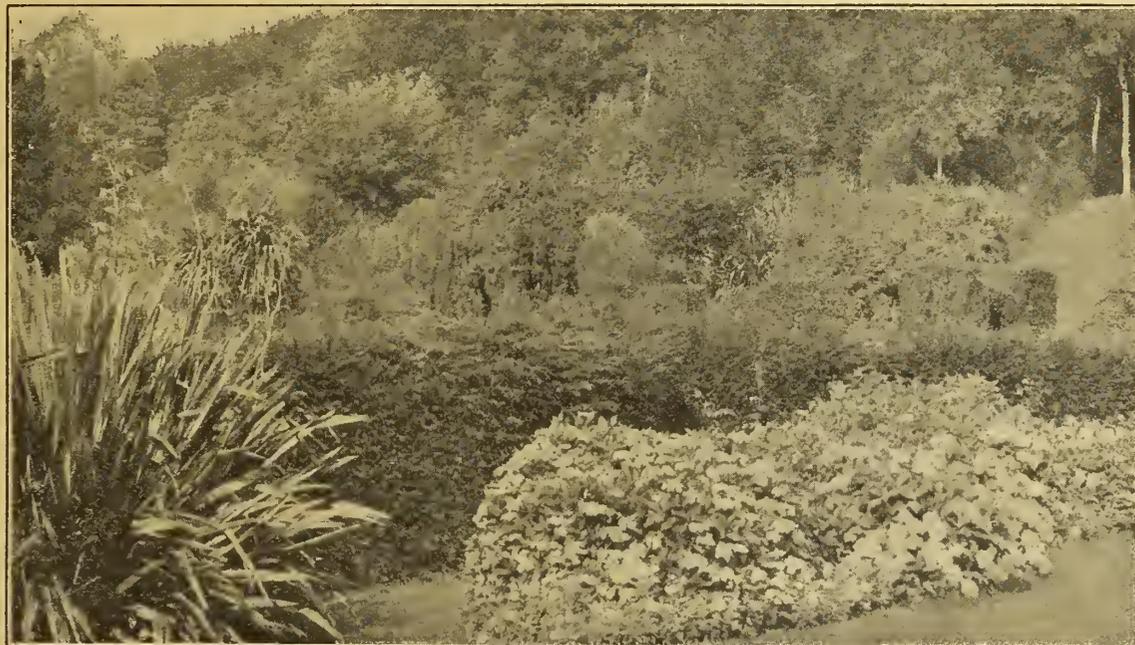

**THE AMERICAN ROCK ELM
(ULMUS RACEMOSA).**

GROWING in a plantation on the Penrhyn estate at 600 feet altitude on a spur of the Snowdon range of hills is quite a number

little difference and not more than could be expected between fully-matured and forty-year-old specimens of the wood. The American Rock Elm always impressed me as a tree that was peculiarly suitable for exposed, wind-swept parts of our country, and though the tree is rarely grown here, yet its growth under trying conditions of both soil and climate in Wales shows it to be a valuable species for afforesting mountain lands. As firewood the timber of the Rock Elm has few equals, burning with a steady, bright flame—the opposite of our English Elm-wood, which is dour and cheerless. The American Elm (*U. Americana*) is of much larger growth than the Rock Elm, but it has not done well in this country. It is offered for sale by some of our nursery firms. The timber of the American Elm is imported, or was a few years ago, in considerable quantity to this country, where its lasting properties gained for it a considerable reputation.

A. D. WEBSTER.

Climbers for house walls.—I want to know the names of the most robust and rampant creepers for planting on the east, west, and

Groups of trees and shrubs at Ashbourne, Glounthaune, Co. Cork.

When the disease appears, the best plan is to mix common stone lime and powdered charcoal in equal proportions, and rub it well into the affected parts with the finger and thumb. This process should be repeated day by day, allowing no moisture from the syringe to come into contact with the wound. This composition will eventually form a hard crust, and finally destroy all cankerous matter. This old remedy has often been ridiculed, but those who have proved its efficacy will not readily discard it.

Black Currants.—A good proportion of these is bottled, and, as in the case of Raspberries, the bottles are filled direct from the bushes. The finest samples are used for this purpose. After the crop is gathered it is advisable to thin out, even at this early date, any exhausted or superfluous wood. I do not mean, of course, that the bushes ought to be attended to for good at present, merely that a certain amount of thinning be done to admit air and sunshine to assist in the maturing of the wood. Fortunately, the bushes are free from big-bud, but, naturally, a vigilant outlook is kept, for the mite is prevalent in the district.—K.

of trees of the American Rock Elm. There, exposed to the fury of the south-west winds, this denizen of calcareous and gravelly districts of Canada is quite at home in a mixed wood of Larch and other conifers. This is easily recognised by the curious thick, corky appendages to the bark of the younger branches and long racemes of flowers, unlike those of any other species of Elm of my acquaintance. Shaly slate rock with a slight coating of Gorse-loving loam may be said to constitute the soil which has not only grown this species, but our native Cornish Elm (*U. cornubiensis*) to perfection, the latter having been planted at 30 feet apart over a 50-acre plantation adjoining.

The American Rock Elm is a stocky tree, not remarkable for quick growth or size, but producing timber of first-rate quality. It is fine of grain, compact, and of a beautiful buff or reddish-yellow towards the centre, and takes on a nice, smooth surface under the tool of the carpenter. A comparison of timber grown at Penrhyn and specimens shown at some of our exhibitions in London revealed but

south walls of a house. The walls are now bare and hideous, cemented over with a creamy shade. The house is really of noble proportions, and in a beautiful but bleak position. My idea is a house entirely covered with the self-climbing Virginia Creeper as a background (two now are doing well), and against these I would plant climbing Roses, yellow Jessamine, Clematises, etc., the most hardy sorts (I hear they do well here). Please tell me what would do best on the different aspects? I hear the south gets very blown about in winter, as from that direction the prevailing wind comes.—LANGTON.

[You can depend on many of the best Climbing Roses, both the Chinas, like *Cramoisie supérieure* and those nearer the Teas, like *Rêve d'Or* and *Bouquet d'Or*; also the finer of the single wild Roses, like *moschata*. You cannot do without the Clematises of the nobler sorts, and the species, like *C. montana*, are sure to do well. There is far too much Virginia Creeper in the world, and you should only have one or two plants, but not as a background. You can easily find out if in the district the *Wistaria*, noblest of all climbers, flowers. Some of the newer climbers from China, as well as the hardy

Vines, like *V. Coignetia*, do very well in the home counties, and we think would do with you. Some of the *Cotoneasters*, *Crataegus Pyracantha*, and on the warm sides *Jasmines* would do, with the hardy *Honeysuckles* everywhere.]

Moving Yew-trees.—I would be much obliged for some information regarding the removal of Yew-trees. I have two Yew-trees, about 25 feet high, and perhaps 20 feet across, which are in the way of some buildings, and must be moved. Would it be possible to transplant them? They are growing rather close together. (1) What is the best time of year to move them? (2) Is it best to dig half round the roots, so as to cut them, several months before moving the tree?—L. IRIS ORPEN.

[The trees might be moved with great expense and care, but as far as one can judge they are not worth it. Besides, Yews near a house are always a danger to stock.]

Colorado Blue Spruce.—This striking Conifer suffers, like so many others of its kind that are horticulturally attractive, from a multiplicity of names. Here we have decided to call it *Picea pungens* var. *glauca*, but in the United States, where it is a native, *P. Parryana* is the preferred name, and it has been called *P. menziesii*. It was first introduced into this country about forty years ago, and at once attracted attention on account of the milk-blue colour of its foliage. In some soils and positions it thrives from the first, but in many places it proved a failure. In Colorado it occurs in certain groves along the banks of streams and in open grassy valleys, the largest trees being found in open positions near water. It dislikes shade more than most Conifers, and likes an open, well-drained soil. Where it is happy it lives to the age of 400 years or more, but, being slow in growth, trees 100 years old may not be more than 4 inches or 5 inches in diameter. Full-sized trees are about 100 feet high and about 2 feet in diameter. The silver-blue colour of the foliage is peculiar to young trees, for it gradually disappears as the trees get older, full-grown specimens being quite green. With age, also, the distinctly pyramidal arrangement of the branches is altered to a less regular outline, and when the lower branches fall away the tree has a less pleasing look.

[This from the "Field," but nothing is said of the green form of the tree, the better of the two. In gardens we are apt to make too much of silvery forms, rarely so enduring in their beauty as the wild form. The normal colour is a bronzy-green. The tree is as hardy as a Scotch Fir.—Ed.]

Magnolia hypoleuca.—This *Magnolia*, though still very rare, has been grown in a few gardens for upwards of twenty years. In Japan it is said to reach a height of 100 feet. On vigorous young plants the leaves are each as much as a foot and a half long and half as wide. Their size is, perhaps, most closely approached by that of the leaves of *M. tripetala*, and exceeded only by those of *M. macrophylla*. The flowers of *M. hypoleuca* are each 6 inches to 8 inches across, white or cream coloured, with a central mass of crimson stamens, and very fragrant. It flowers in summer after the development of the leaves. The fruits are cone-shaped, each 6 inches to 8 inches long, and bright red or scarlet in colour. Like other *Magnolias*, it requires warm, loamy soil, and appreciates a little peat placed about the roots at planting-time. It shares the dislike of other species to frequent root disturbance, therefore it should be given a permanent position when quite small. Although sometimes grafted upon stocks of other kinds, the best trees are those which have been raised from seed.

PLANTS AND FLOWERS.

CHRYSANTHEMUMS.

CHRYSANTHEMUM NOTES.

By this time the roots will require feeding, for whatever was put into the soil at potting time in the way of manure will have been used up during the warm spell of weather we have lately experienced. Probably there are instances where the foliage presents a sickly, starved look just now. This is an indication that water alone is not enough to keep the plants in a vigorous condition. Feeding may be done in more than one way—that is, by liquids made from animal manures, and by the use of artificial manures. For growers in towns the latter are the more easy to obtain, and good results should follow the employment of either, or both. Animals that feed on Grass supply us with material that is excellent because its nature is cool, and even if used in a strong state the roots of the plants are not likely to be burned. This may be collected, placed in a bag, and then thrown into a tub of water. In a week or so its virtue will be gone, then a fresh supply should follow. The quantity to be used with water is difficult to name, but when fresh one should be more sparing than as days go on and the liquid weakens. Soot-water prepared in the same way, in a bag, is a capital stimulant. Care, however, should be taken that this is quite clear, and not over strong. Put enough into the can to just colour the water and all will be well. Manure from the chicken-run is first-rate, too, made into liquid, but this being, like soot, of a hot nature, requires care. That is to say, weak doses and often should be the rule. In fact weak and regular should be applicable to the use of all liquid manures.

Respecting stimulants in the form of dry powder, which may be given at intervals of three or four days, it is best to apply them as a surface dressing and water them in. There are few of these all the parts of which form readily into a liquid state, and the sediment left on the surface of the soil will encourage roots. In the case of artificials, as we term them, it is not easy to state offhand the quantities to be used. Each has usually full instructions when sold. At the same time, if a general rule that a teaspoonful be used for a flower-pot of 10-inch diameter—and less, of course, for a smaller one—we shall be on the safe side. Sulphate of ammonia, sometimes recommended for *Chrysanthemums*, requires even greater care, and one ounce to two gallons of water will not burn the roots. One thing should always be remembered about fertilisers, liquid or otherwise. In themselves they are practically useless to plants in pots if other important items, such as abundance of roots and no neglect of watering, have not been assured. Just now we are in the season of

BUD-TAKING, a cultural point which has perhaps been made to appear anything but simple. If the cultivator has once learned what a crown-hud is then the matter is not by any means difficult. Anyway, "crown" huds should be plentiful early in August, and these flower-huds can be noted at the tips of the young growth. A hud may be found in the centre of a cluster of tiny shoots. Take the latter away and leave the flower-bud, then we get the same to develop into a big bloom because of the time for the same to do so—well into October or November. If the hud be not saved the tiny shoots will go on and smother the former, and these

in their turn will produce clusters of flower-buds. The only thing an exhibitor of giant flowers has to learn and remember is as to the better date for each variety to produce its crown-hud so as to give a highly-developed bloom at a time desired, and so propagate the plants accordingly. In the past this phase led to much "stopping" and "timing," which probably never assisted to any great extent. In any case the better cultivators of to-day try simply to grow their plants well throughout the season and depend upon crown-buds even if these appear as early as July. This, of course, refers to exhibitors. Growers generally may follow the early flower-hud selection if large flowers are desired; or let the blooms come in their own season—he it late or early—with the aid of thinning to induce the growth of large blossoms, if, indeed, these may be comparatively smaller than those from crown-buds. One thing may be added: Early-formed flower-buds produce blooms of extra size and very double, but the colours of all except yellows and whites, perhaps, are not of striking brilliancy, nor are the individual petals notable for good quality.

Allow the plants abundance of room; this rule cannot be insisted upon too often. Both for profit and pleasure it is better to have a dozen specimens that will produce good flowers than a hundred with soft, ill-matured growth which, more than likely, will give "blind" buds or at the best weakly and unsatisfactory blooms. One always regarded the examples exhibited by Mr. F. S. Vallis, Chippenham, a few years back, as being about as good as any *Chrysanthemums* ever seen, and he paid great attention to the matter of room. Thinning the growths in time—that is, before they are far advanced, is another detail that needs thought. We should make up our minds early as to the number of blooms intended on each plant, and take away everything that is superfluous.

H. SHOESMITH.

NOTES AND REPLIES.

Shoots at base of Chrysanthemums.—I have a number of *Chrysanthemums* which I grow for special blooms. Several which I have disbudded are now showing shoots from the roots. If I let these grow can I take them as cuttings, and will they bloom this season, and will they injure the progress of the plant or the size of the flowers?—GROWER.

[If you desire to grow large, handsome blooms on your plants you should remove the shoots now quickly developing at their base. These shoots seriously interfere with the prospect of a successful blooming, and there should therefore be no delay in carrying out this seemingly drastic treatment. Care, however, should be exercised when removing the shoots, so that no damage shall be done to the roots in the operation. It is a very simple matter. With a sharp knife detach the shoots, making the cut immediately below the surface of the soil. By these means there is no risk of damaging the surface roots, which assist so much in the development of the special blossoms you wish to produce. You may insert the cuttings in any light sandy soil, using boxes or small pots for the purpose; in fact, propagate them as was done with others earlier in the season. When the cuttings are rooted, pot them up singly into 3-inch pots and when these in turn are well filled with roots give the plants their final shift into pots either 4½ inches or 6 inches in diameter. Grow the plants on freely from their first potting, and retain the first bud developing in the point of the shoot. Rub out all other growths, leaving the bud absolutely alone

at the apex of the shoot. The buds should develop sufficiently early for the resulting blooms to attain excellent proportions, and they should also provide you with a nice late display.

ROCK, ALPINE, BOG, FERN, AND WATER GARDENS.

PENTSTEMON HETEROPHYLLUS IN ROCK GARDEN.

THE wealth of America in Pentstemons is remarkable. There are many beautiful kinds, but some are not quite hardy with us. I have never seen this very beautiful American plant so happy and so vigorous as at Friar Park, embraced by rocks. *P. Scouleri* is hardy even in London gardens, and *P. isophyllus* is hardy with me. From the vast range of the Rocky Mountains we might expect others. The most graceful so far we grow is the one here shown, a

species, also planted in mortar-rubble but without a rock behind, do not flower with anything like the same freedom.—STUART HOGG, *Roxford, Hertingfordbury.*

— I have always looked upon *Saxifraga oppositifolia* as one of the most free-flowering of all the species, and it was interesting, therefore, to read Mr. J. Cornhill's note in GARDENING ILLUSTRATED, September 2nd, page 440, telling what a shy-flowering plant it is with him. My pot-grown plants of *S. oppositifolia* (and its various forms), of which I have several thousand, are covered with blossom every spring with the utmost regularity and almost unbelievable freedom, and it is the same with planted out specimens. The pot plants are in a good, free, gritty potting mixture, decayed turfy loam, silver sand, a little leaf-mould, and a dash of gritty broken flower-pots. At present I only have planted-out specimens on a limestone moraine, but in the past I have had

in the soil, or to the air of Stevenage, or possibly the plants make mountains out of what M. Corveon called the six molehills, and are led to believe that they are back in the Alps. But if Mr. Cornhill has not tried the top-dressing he might find it worth while to experiment, and I would suggest the addition of a little lime in some form to the mixture.—CLARENCE ELLIOTT, *Stevenage.*

— Mr. Cornhill, at page 440, complains of *Saxifraga oppositifolia* not flowering. I used to have the same trouble with it until I planted it on a northern slope in rough limestone rubble and loam. Since I did this it has been every year a great sheet of bloom about 5 feet by 3 feet, the blossoms so thick as to quite hide the foliage. I noticed in the Alps that it grew best in semi-shade, and after 11 a.m. my patch gets but little sun. It is now one of the most reliable and satisfactory things I have. The beautiful variety

Pentstemon heterophyllus in the rock garden at Friar Park.

beautiful flower-garden plant. Where not hardy it deserves frame protection in winter. It is well worth raising from seed. W.

SAXIFRAGA OPPOSITIFOLIA.

IN the issue of GARDENING ILLUSTRATED of September 2nd Mr. Cornhill asks what are the conditions which produce the maximum amount of bloom in *Saxifraga oppositifolia*. I have two plants which, planted side by side some ten years ago, are every year such a mass of bloom that the foliage cannot be seen. They cover a space 3 feet by 2 feet and are a goodly sight in February. They are planted in a raised bed of mortar-rubble under a large rock, the aspect south-west. I attribute their free-flowering to the fact that their roots go under the rock behind them and are thus kept moist while the poor stuff in which they are planted forces them to flower. I am confirmed in this view by the fact that other plants of the same

them in gritty loam on ordinary rock garden. I always grow them in full sun, except the variety *W. A. Clark*, which scorches badly and should have a west or north-west aspect, and in dry weather they are watered. Not long after flowering they should be top-dressed. A thick dressing of the same soil as that in which they are growing is as good as anything. I scatter it over the plant so thickly that only the tips of the leaves are visible. Rain or subsequent waterings soon wash this top-dressing in, and it keeps the plants strong and vigorous, prevents their dying off brown in the centre, and possibly induces the formation of flower-buds for the following year. I sometimes top-dress in this way two or three times during the spring and summer, and the result is an annual mass of blossom which entirely hides the plants. Of course, the free-flowering of my plants may have nothing whatever to do with this top-dressing. It may be due to some unknown constituent

W. A. Clark is much less free, but the variety *Latina* is as good as the type.—R. L. ROUTH, *Sibford Ferris, Banbury.*

— This type generally does well in gardens about here. My experience is that it flowers well when it spreads horizontally over porous stone, such as a slab of millstone grit, and badly when it spreads over earth. Aspect is immaterial, though a patch I have on a bank exposed to the north blooms at least a fortnight later than in some neighbouring gardens which have a southern aspect. It does not need lime.—L. J. ROGERS, 6, *Hollin-lane, Leeds.*

NOTES AND REPLIES.

Epilobium Dodonæi.—Flowering in August when the rock garden is none too gay, this species is more attractive than it would be earlier in the year, when it would be overshadowed by its more brilliant neighbours. It is quite a pretty little plant, and gives profusely of its small purplish-crimson flowers, and is of neat and dwarf habit, with no tend-

ency to stray out of bounds—at least, it does not with me. I grow it in a sunny position in very gritty and limy soil on a raised part of the rock garden, where it seems quite happy, and flowers very freely.—W. O. C.

The Meadow Saxifrage (*Saxifraga granulata*).—This is well worth growing in the rock garden, both in its single and double forms. It is found wild in damp meadows, and in cultivation, cool, half-shady positions suit it best, and when it is at home it rapidly increases. Associated with Primroses, Cowslips, wild Orchis, and other spring flowers, it looks very pretty in a partially shaded part of my garden, which I have planted with these lovely wild plants, which flourish in spite of the somewhat smoky condition of a London suburban garden.—N. L.

Saxifraga Alberti.—The names of the encrusted Saxifrages are legion, but this in my opinion is one of the best of the larger ones, both as regards foliage and flowers. It has long, rather narrow leaves of a deep bluish-green, heavily encrusted, and very handsome spikes of white flowers, which last in beauty a long time. Like most of its family, it likes a sunny position with a cool root-run in limy soil, wedged in between rocks, and is then as easy as any, and beautiful all the year round.—W. O.

Veronica satureioides.—Among the many Veronics for the rock garden this is useful as being one of the earliest to come into bloom, although it is not so brilliant as some of the other creeping Speedwells. It is of quite prostrate habit and neat growth, and does not encroach on its neighbours. Like so many of its family, it roots from its creeping stems, and so is readily propagated. It blooms in May.—N. L.

Trollius patulus.—This is quite distinct from the usual type of *Trollius*, the flowers opening flat instead of globe-shaped. It flowers about mid-July, its large, deep-yellow blossoms, each often 3 inches in diameter, making a fine patch of colour in the bog garden. It is of easy culture in rich, boggy soil, and seems quite happy in semi-stagnant conditions provided the crowns are raised well above the water level.—W. O.

Spiraea decumbens.—Unlike many of its relatives, this tiny little *Spiraea* only grows a few inches high, and so is admirably adapted to the rock garden. It is of neat habit, with small, whitish flowers, and quite pretty when grown into a nice clump. It never ramps, though it grows fairly freely when established, and likes a sunny and fairly dry position. It can be freely increased by division.—N. L.

Saxifraga cuneifolia.—I think this is one of the neatest and prettiest of the London Prides, the small rosettes of fleshy, rounded leaves being very attractive, though its flower-spikes are not so handsome as some. It does not like a too sunny position, and seems to suffer from drought, but is very happy among stones on the cool side of the rock garden.—O. C.

Veronica spuria.—This was in bloom in the Botanic Gardens, Oxford, on June 17th. It grows from 1 foot to 1½ feet high, and is well covered with sky-blue flowers produced on branching stems. It is a good bee plant. Any good soil seems to suit it so long as the position is sunny, and it looks well also in the rock garden or on walls.—E. T. ELLIS, *Weetwood, Ecclesall, Sheffield*.

Veronica saxatilis.—This is one of the best of the dwarfer sorts, and can be grown in the rock garden, on the wall, or on the margin of the herbaceous border. Any ordinary soil suits it, and the position should be sunny. Its height is from 4 inches to 6 inches, and the flowers are of a lovely pale blue.—E. T. ELLIS, *Weetwood, Ecclesall, Sheffield*.

Sifting soil (*Anon*).—Unless for seedlings and newly-rooted plants the rougher you can have the soil the better. Do not sift it, as this takes away all the fibre, the most important constituent in the soil. Note how the roots of a plant cling round the fibrous pieces of loam that are used for potting *Chrysanthemums*, *Pelargoniums*, *Fuchsias*, and such like. We have some *Aspidistras* now that are potted in only the fibrous pieces of loam and some silver sand, with a little manure, and they are very fine specimens, the pots being quite filled with roots.

GARDEN FOOD.

MARROWS.

AT this time of the year, in almost any garden, Marrows are very plentiful, and they deserve better cookery. The Italians, who are experts in the art of frying, make good use of the young Marrows. I never tasted them quite so good as at Milan, fried in thin slices, as dry as nuts. There is a mass of valuable food neglected in this way by rich and poor alike, the common way being to dish it up in a watery mess. The origin of the plant is not easily solved. Its native land is said to be tropical Africa. It is as easily grown in our climate in summer as the hardiest vegetable, and is most wholesome when well cooked, and more valuable in that way than some popular vegetables. The various kinds seem about the same in value in cookery, but some prefer the compact forms as more nutty in flavour. Cottagers often let them grow too large.

MARROW AU GRATIN.—Peel the Marrows and divide into round pieces of about 1½ inch in diameter. Blanch in salted water for a few minutes, and drain on a sieve. Butter a gratin-dish and arrange the Marrow in it, season with salt and pepper, sauce over with a little Béchamel sauce, and sprinkle with grated cheese, half Gruyère and half Parmesan. Bake, and brown nicely and serve hot.

MARROW A LA LYONNAISE.—Peel the Marrow, cut it in half, and remove the seeds; then cut it into small cubes about 2 inches long. Place them in a basin, with a tablespoonful of salt, cover, and let stand for twenty minutes. Wash well, then drain. Put them in a saucepan with 1 oz. of butter, a pinch of pepper, a teaspoonful of sauce, a bouquet-garni, and a little stock. Braise and drain when cooked. Slice a peeled Onion, toes in butter, and when of a nice colour pour off the butter and mix with the Marrow. Stew gently for a few minutes. Add a little chopped Parsley.

MARROWS AND TOMATOES.—Take three good-sized Tomatoes; take out seed, place in a stewpan with one large Potato, one large Onion, sprig of Thyme, and Parsley; fry together a few minutes, add one gill of stock, boil for fifteen minutes, pass through a hair-sieve, put into stewpan, add one tablespoonful grated cheese, season, cover the Marrow, place in oven ten minutes.

SAVOURY MARROWS.—Peel a Marrow, cut it into convenient pieces, place them in a stewpan with half a sliced Onion, spread over with butter, and season. Moisten with a little white stock and white sauce, and cook till tender. Reduce the sauce to a glaze, add a pat of butter, a little Lemon-juice, sprinkle with chopped Parsley, dish up, and serve.

MARROWS WITH CHEESE.—Peel two green Marrows, not too large in size; cut them lengthwise into quarters, scoop out the seedy parts, place them in a sauté-pan with 1 oz. of butter, season with salt and pepper. Put the pan on the fire for a quarter of an hour, shaking it from time to time; moisten with a little cream, and add a tablespoonful of grated Parmesan cheese. Dish up the Marrow neatly on an oblong dish; sprinkle with breadcrumbs and Parmesan cheese; place in a hot oven for a few minutes.

Whatever way of these is followed, it is essential not to over-cook and reduce to a pappy mess. That way spoils the dish and destroys the natural salts of the vegetable.

MARROW SOUP is made thus: Boil the Marrow till very tender, previously removing the seeds, drain, and pass through a sieve, add to the pulp some milk or stock, season with salt and pepper, and, if necessary, thicken with a little flour rubbed into hot butter. Serve with fried bread.

Why do we not grow the American squashes which afford such a fine supply of food in winter?
W.

CARDOONS, BLANCHING AND COOKING.

You often give good recipes for cooking vegetables. Could you give one for cooking Cardoons? I have a nice row, grown on the flat and then earthed up. They look very well, but I am told they should have been wrapped up in hay-bands. What is your opinion?—HENRY GAIR.

[For growing the Cardoon a trench prepared on similar lines as for Celery is needful, the plants having a space of 2½ feet between them and a distance of 3½ feet to 4 feet is required between the trenches for earthing up in the autumn. Earthing up should not be done until the growth is finished, previous to which the leaves and stems must be tightly bound up with hay-bands to exclude air and prevent the soil getting in among the leaves and stems. Six weeks or more must be allowed for blanching and then they must be lifted and stored for winter use in a cool, yet frost-proof, building, or, at any rate, in some place where they can be kept free from frost. A cool cellar is a very good place, and here they may be stood with a ball of roots attached, and, if not too damp, the blanching still continues. If you have no place to store them in this way they can be protected where growing by placing litter along the ridges. The advantage of lifting them, however, is that they can be got at easily in severe weather, whereas those left outdoors sometimes cannot be dug up owing to severe frost. The blanched stalks or ribs of the inner leaves are chiefly used as a winter vegetable, as well as the main root, which is thick, fleshy, and tender, and of an agreeable flavour.

COOKING.—To cook Cardoons, wash them in water, and leave them in vinegar and water until about to cook them. Boil them in an enamel saucepan in milk and water (three parts of water to one of milk) until tender. Drain them, and serve with melted butter. The French way is to melt a small piece of butter in a saucepan, and when they are well drained put them in and add a small quantity of good brown stock. The Italians place them in a very hot dish after draining them, and sprinkle them with grated Parmesan cheese, which they allow to melt into them.]

NOTES AND REPLIES.

Early Potatoes.—The season, on the whole, has been favourable for the development of early Potatoes, and the crop is good, while individual tubers are of quite an exceptional size. Every grower has, of course, his favourite varieties. Personally, I depend on May Queen and Mid-Lothian Early for the earliest supply in the open. The former is a very early-maturing Potato, and if not a very heavy cropper it yet gives quite a good yield at a very useful time. It is a Potato which possesses a good flavour—a point occasionally wanting in first earlies. Mid-Lothian Early turns in just as May Queen is finishing and is both a well flavoured variety and an excellent cropper. Beauty of Hebron follows Mid-Lothian Early, and, if old, still remains a useful all-round Potato. This in turn is succeeded by Puritan, and with these four varieties the average demand can be met until the later sorts are fit for lifting.—W. MCG.

"The English Flower Garden and Home Grounds."—New Edition, 12th, revised, with descriptions of all the best plants, trees, and shrubs, their culture and arrangement, illustrated on wood. Cloth, medium 8vo, 15s.; post free, 15s. 6d. Of all Booksellers or from the office of GARDENING ILLUSTRATED, 63, Lincoln's Inn Fields, London, W.C.

OUTDOOR PLANTS.

A COTTAGE PORCH.

IN our cool land the porch fulfills the purpose which the loggia does in warmer lands. It is a comfort in many ways and may be beautifully covered. This one was at first made of open Oak-work in the upper part, but being in a cold and windy position it was found better to panel it within so it becomes a sun trap. There are two Oak benches and it is large enough to serve for a place for a meal on fine days. The inside space is about 6 feet by 6 feet; low walls of brick. When such a porch comes into a garden all the greater the charm. The porch may also improve

creased either by division or from seeds, which it produces in profusion. It flowers in June and is especially welcome for its colour at a time when there are not so many yellow and orange hues in the garden as there are later in the season.—W. O.

HARDY FLOWER NOTES.

HERBACEOUS PHLOXES.—The advantage of growing a portion of the stock in a semi-shady position is once more apparent. At the time of writing, plants in the open are past, a great portion of the trusses frizzled up in the hot sun. Good waterings would have, in a great measure, neutralised the effects of heat and prolonged drought, but one cannot water

in vigour with me, whereas *P. Mariesi* seems to stand still and frequently disappear, probably through the combined influence of wet and cold, which lowers the vitality of many things that come from Japan. On several occasions I have saved a good lot of seeds from this *Platycodon* and they came up well, but they disappeared during the resting period at the rate of 95 per cent. I can only think that this hardy plant is affected by local conditions, and, like some other things, will in some places flourish indefinitely and refuse to become established in others. Good drainage I believe to be imperative, the nature of the roots tells us so.

ANTIRRHINUM COTTAGE MAID is a very taking variety, the soft pink and white of

Porch. Moat Cottage, Gravetye.

the look of a cottage. Before this porch was added the cottage was a very commonplace affair. Mr. Alfred Parsons gave me a little sketch which was carried out with local materials, and ever since it has been a comfort. W.

Inula glandulosa. — This old-fashioned plant is not so often seen in good condition as its merits deserve. I think it is by far the finest of the *Inulas*, but it is a slow-growing plant and is not seen to fullest advantage until it has become a good-sized clump. It responds to good cultivation, its flowers being then each 5 inches or 6 inches in diameter, or even more. A large group, when in full flower, makes a striking effect in the border. It is in-

everything. Those where the sun passes away about mid-day are quite fresh. Those who need flowers for cutting should make note of this, as the *Phlox* bulks largely where bunches of outdoor flowers are in request.

SAXIFRAGA CRENULATA. — This species cannot be classed among the aristocracy of the family, but it is pretty when in bloom, and the foliage is pleasing. It also has the merit of being of easy culture, and is a good thing for beginners in the culture of alpine to take in hand. It should be a good companion to the *London Pride*.

PLATYCODON MARIESI. — I fancy that this is not quite so hardy as the old *P. grandiflorum*, which has yearly increased

the flowers presenting a delicate harmony of colour which is not often found in hardy flowers. As regards habit of growth and free-flowering it is all that can be desired.

AQUILEGIAS. — Unfortunately, some of the most beautiful species, such as *A. alpina*, *A. cœrulea*, *A. glandulosa*, and *A. Stuarti*, are, in a general way, short-lived when treated as ordinary border plants. *A. chrysantha* is much stronger, and, given plenty of space in a sunny aspect in a free soil, it will take on perennial vigour, and, in the form of three-year-old specimens with hundreds of blossoms, is extremely ornamental. *A. Skinneri*, in its true form, is not quite so robust, but what one usually gets from seed differs con-

siderably from the true form, the colour of the flowers not being so intense, but the growth is stronger, and these seedlings are capable of holding their own when in companionship with other things so long as they get fair play and have not to go through the semi-choking process which many things have to undergo in the mixed border. As regards the first-mentioned species, there are, in my opinion, no dwarf-habited plants more worthy of careful culture than these little Columbines, as they are so distinct and so well fitted for small gardens. What they want is a place to themselves in very free, well-drained soil, where they can be attended to. Failure is apt to occur, more or less complete, if they are mixed with other things unless they can be given a place in the rockery, and by reason of their elegant growth and dainty blossoms they are as worthy of a place of honour as the majority of alpine plants. The hybrid forms, which can be raised from seeds, are very beautiful, varying much in vigour according to the way in which they have been influenced by their respective parents. Where the *A. chrysantha* and *A. Skinneri* blood prevails they are more vigorous than when descended more directly from *A. cerulea*, *A. Stuarti*, and *A. alpina*. Unless these seedlings are well watched the weaker plants will disappear, and some of the most delicate and charming shades of colour will be lost. The fact is, these long-spurred Columbines need special culture if they are to have perennial life, and they are worth it, for they are among the most precious hardy flowers in cultivation at the present day. J. CORNHILL.

BEGONIAS FOR THE FLOWER GARDEN.

Will you kindly tell me which you consider the most effective Begonia for filling large beds on a terrace? I like the kinds that have small flowers in abundance, narrow leaves, and from about a foot high. If I sow seeds of these in January will they make good plants for planting out in spring?—A. M. B.

[The most effective of the named varieties of tuberous Begonias for the flower garden are Major Hope (rose) probably the best of all, Lafayette double scarlet and Worthiana single scarlet. Tubers of these would have to be purchased, as you would not be sure of getting them true from seed. If you prefer to raise your own plants purchase seed from a good firm, stipulating that you require very free varieties with rather small, erect flowers. Sow as suggested in January and grow on as quickly as possible so that they are nice stocky stuff by the time it is necessary to harden off for planting outside. Under such conditions there is no difficulty in obtaining a fine display the same season. If you require special colours of the habit indicated it is better to put this batch of plants into prepared beds in the reserve garden. Select when in flower and propagate for another season.

Great care is necessary in the sowing owing to the very tiny seeds. Have the surface of your seed-pan perfectly level and fine, with the soil sufficiently moist to promote quick germination. Cover very slightly and shade until the seedlings appear. If you decide to plant your batch of tuberous varieties in reserve beds, and select, perhaps you would like to use the fibrous section in the flower garden next summer. These come true from seed, make a fine display, and continue in flower well into the autumn; also they are about the height you require. Scarlet Beauty and Salmon Queen are good varieties. In the case of both tuberous and fibrous sections you might,

if the beds are small, fill each with one variety, but with large beds it is advisable to plant the Begonias in small groups and carpet intervening spaces with *Koniga variegata*. A pleasing break is provided by an occasional plant of *Grevillea robusta*.]

PARRYA MENZIESII.

The Parryas are a small group of, for the most part, bushy growing plants belonging to the order Cruciferae, and are interesting rather than possessed of a beauty calculated to render them popular as garden plants. That they have their uses there is no doubt, and it remains for the intelligent cultivator to find out the conditions best suited to their requirements. The general habit of the species is that of low-growing glabrous or pilose, herbs, some, like the above, more after the manner of *Alyssum saxatile*, though the much smaller leaves are roundly crenate at their margins. Strictly of perennial duration, they are best regarded as biennials, and thus treated, sowing the seeds each year when ripe, are capable of pretty effects. Disliking rich vegetable soils, and short-lived in such, they should be planted either in stony ground or in fissures where rocky debris abounds. Firm—I had almost written hard—planting is most desirable, essential, indeed, in conjunction with the position named to secure longevity. The species are native of Arctic regions generally, *Parrya Menziesii* coming from north-western America. Its flowers are violet-purple. There is a white-flowered form, and occasionally varieties having striped flowers appear. Early spring is the flowering period, though this may vary with cultivation and locality. Its height is from 6 inches to 9 inches. E. H. J.

NOTES AND REPLIES.

Gerardia tenuifolia.—Will you kindly name the enclosed for me? It came to me from a very interesting garden in Devonshire as a *Gerardia*, but looks very much like a variety of *Pentstemon*. It does not keep well in water, and I fear it may not travel well.—CHARLES PRENTIS.

[It is *Gerardia tenuifolia*, the only kind we have seen growing in England. An American kind of much beauty, *G. purpurea*, grows on the roots of other plants. It would be worth while to get seed and try to naturalise it with us.—ED.]

Lilium giganteum bulbs, treatment of.—I am expecting shortly some bulbs of *Lilium giganteum* from Darjeeling. Should I plant these in the open at once or store them till the spring?—W. M. CROWFOOT.

[If the district in which you reside is considered a favourable one generally for Himalayan plants you may plant the above-named in the open to the end of the present month with safety. After that time the bulbs would be better potted and placed in a cold frame, and, if plunged in ashes or coconut fibre, would require little or no water during the winter after the first application to settle the soil. Dry storing takes too much out of this species and should not be indulged in. It is to be hoped that the bulbs you are expecting will be not more than half-grown—planting the biggest bulbs is, invariably, a most disappointing business. The planting stations in the open must be well prepared, the species succeeding best in a considerable depth of rich, light loam and in thin shade. For the safety of the freshly-planted bulbs it would be well, for the first winter, to protect them with light litter, leaves, or like material.]

Campanula Elatines.—This pretty and interesting species is too rarely seen in cultivation. A native of the Alps of Piedmont, Liguria, Naples, etc., and usually

found in shady, rocky places, it is, under cultivation in this country, admirably suited to rock crevices, and, in such, if planted in broken rock and soil in equal parts, is hardier and more enduring than in a freer soil away from crevice or fissure. I see no reason for giving it shade in this country, provided a good depth of fissure is assured it. With an inclination to trail after the manner of *C. garganica*, it cannot boast the robust habit and freedom of flowering of that kind, or even its hardiness, hence it is better planted as suggested. The small flowers are axillary, bluish-purple in colour, with deeper-coloured base, corollas very deeply divided, the pointed lobes strongly recurved and distinctly grooved. The leaves are heart-shaped and coarsely-toothed, and in the young state downy. Flowering in August, it is valuable at a time when good alpines are scarce.—E. H. JENKINS.

Crinums.—There are many gardens in neighbourhoods near the sea in which these fine bulbous plants would succeed. They are well suited in a rich, warm border with, if possible, the shelter of a wall or of a greenhouse gable, and in a position where they will not be disturbed. In such a position the ripened foliage will be a sufficient protection during even a severe winter. Where the protection of a wall is absent a barrowful or two of leaves, held in position by a piece of wire-netting pegged down, will be ample. The blooms, borne in umbels upon long stalks, are useful for cutting in autumn. *C. capensis* and *C. Moorei*—the former pink, the latter white—are the best forms for outdoor cultivation.—W. MCG.

Hardy-flower borders.—At the present time the display of bloom in the hardy-plant borders is very fine. In addition to the plants which have from time to time been referred to, mention may be made of the Sea Lavender (*Statice latifolia*), one of the most attractive members of the family. The Gauze-flower (*Gypsophila paniculata*) is useful alike in the border and in a cut state. Large pieces of *Helianthus rigidus* give a fine touch of yellow, while the later-flowering *H. Miss Melish* will prolong the display. An attractive and distinct plant is *Lysimachia clethroides*, with its spikes of white bloom. The purple Loosestrife (*Lythrum roseum superbum*) is also very free. Among the taller plants, *Rudbeckia laciniata*, if not one of the choicest varieties, is noticeable; and *Napæa dioica*, with its handsome foliage, attracts attention. The approach of autumn is heralded by the earliest Asters and by the opening of the Japanese Anemones. Altogether, the close of summer is one of the brightest periods in the calendar of hardy-flower borders.

The Dove-dale Mimulus.—It is worth making the journey in late July from North or South to this secluded heart of England, if only to see the glorious masses of *Mimulus luteus* lighting up the rippling waters of the Dove. Whether a native or a garden escape, it is at this time the glory of the Dove, and seems equally happy on marshy banks or on islets of debris in mid-stream, frequently submerged by the current. Curiously, the *Mimulus* of the Dove has a few reddish-brown spots or blotches (one very decided one on the lower lip) which give it great distinction; whereas the plant growing equally luxuriantly in the Manifold, a tributary of the Dove, is pure gold.—The Garden.

Salvia turkestanica.—This is a handsome plant when in blossom, for though the flowers are small, they are surrounded by large lilac-pink bracts, the soft, harmonious colouring of the two combined having a very pretty effect. It seems quite hardy and an easy doer in ordinary garden soil, a good group of it being very effective in the herbaceous border in August. Unfortunately, it has rather an unpleasant smell, which is not particularly noticeable with a single plant, but a large clump on a sunny day is apt to be offensive when one is close to it.—N. L.

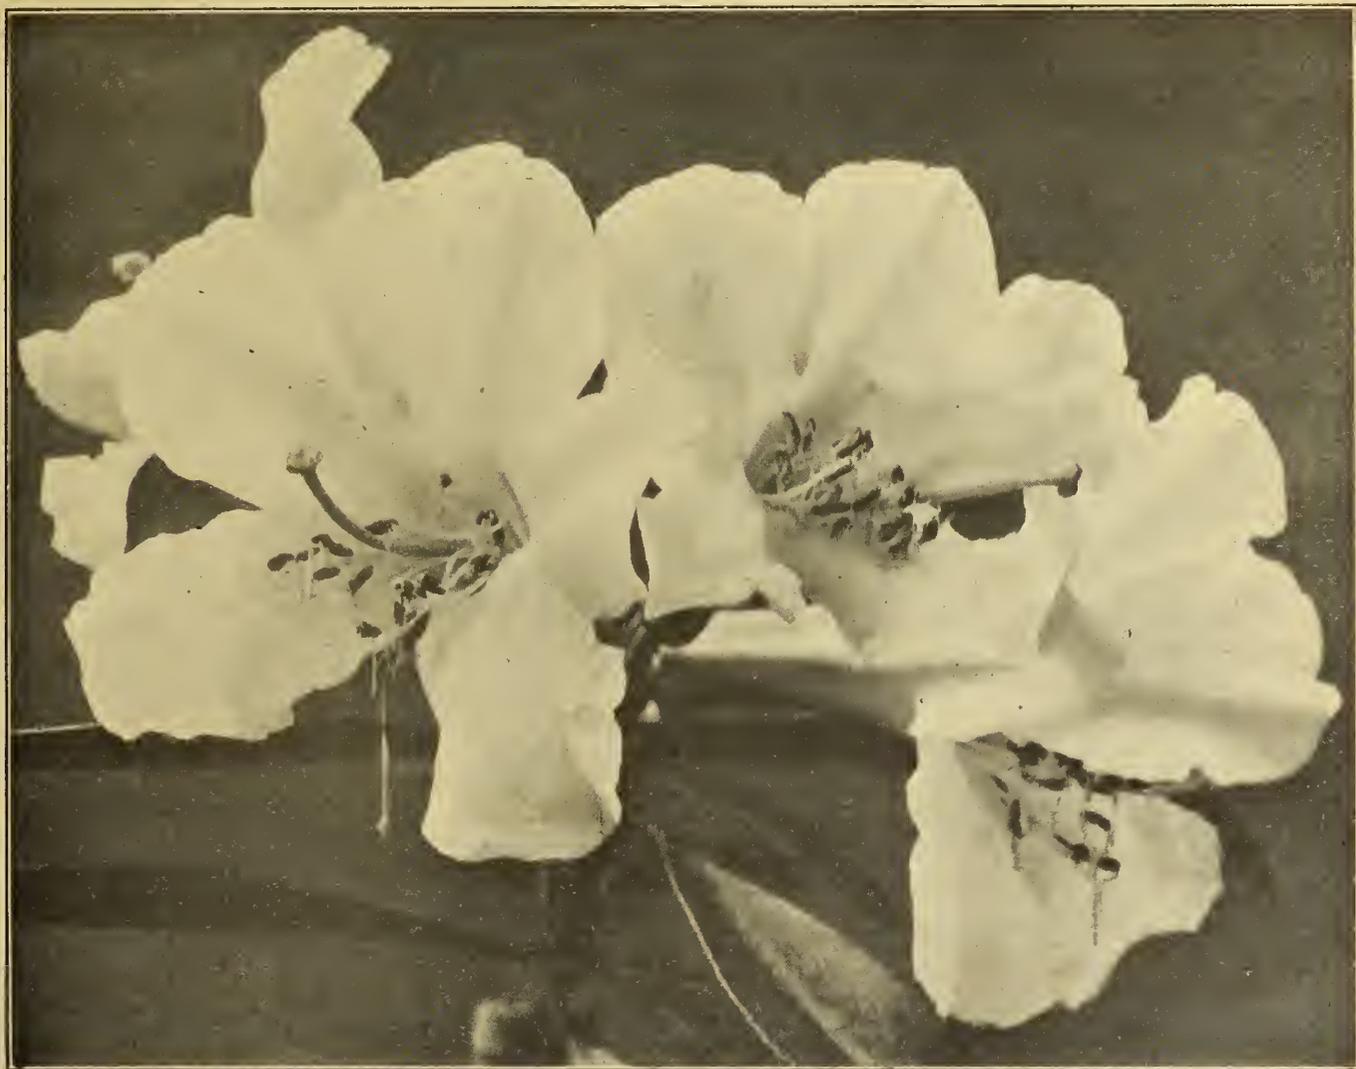

INDOOR PLANTS.

RHODODENDRON MADDENI.

This is one of the most tender of the Himalayan Rhododendrons, and also one of the last to unfold its blossoms, for its white, tubular-shaped flowers may often be had well on into July. The flowers are not borne in compact trusses as in *R. arboreum* and many others, but in loose heads, with, as a rule, not more than half a dozen flowers in a cluster, while they are frequently fewer. Individually they are from 3 inches to 4 inches long, and as much across the expanded mouth, the colour when fully expanded being pure white. Different names that have been

and your plants want repotting, the best time to do this being the spring, just before the plants start into growth. After being potted they should be watered whenever necessary. A suitable compost may be formed of two-thirds good turfy loam, and the remaining third made up of leaf-mould, dried cow-manure, and sand. At the same time, we may point out that *Agapanthus* flower better when the roots are fairly pot-bound than if growing too freely. For all this, root constriction must not be carried to excess, and any which in your opinion would be better for larger pots should be shifted next spring. If any of them are not repotted it will be a great advantage to

of attention than during great heat or drought, for the pots, being full of roots, it takes a heavy rainfall to wet the ball through, as the foliage of the plant carries a large proportion of the rain quite clear of the roots. Consequently only the surface is wetted, but this, with the frequent damping of the foliage and moist condition of the atmosphere, causes the plant to show but little of the ill effects for some time, although it does not grow at all satisfactorily, and if the owner were to turn a few of the plants out of their pots he would probably find them dust dry at the lower parts of the pots, and for this reason it is especially desirable to give plants a thorough good soaking of water

Rhododendron Maddeni. From a photograph at Nymans, Sussex.

applied to this *Rhododendron* or to slight forms thereof are *calophyllum*, *Jenkinsi*, and *virginale*. Seedlings even from the same pod show a certain amount of variation. Plants four or five years from seed and in pots 5 inches to 6 inches in diameter will often flower, thus taking much less time than some of the Himalayan species. A notable feature of this *Rhododendron* is the manner in which the old bark peels off the stems after the manner of *Arbutus Andrachne*.

NOTES AND REPLIES.

Growing the *Agapanthus*.—Will you kindly let me know how to treat the *Agapanthus*? I have three large pots full, and there is only one flower amongst them. I have had them a long time.—ELLA.

[The soil is evidently quite exhausted

assist them during the growing season with occasional doses of liquid-manure or one of the many concentrated plant foods now so much used. During the winter the *Agapanthus* may be kept in a shed or stable where there is a little light and the plants are safe from frost. No water will be needed throughout the winter. In spring, however, when ready to start into growth, the plants must be watered. It is then necessary to remove them to a lighter position, such as a greenhouse, conservatory, or cool vinery, as, if left in semi-darkness, the new leaves will become so weak as to topple over and quickly turn yellow.]

Watering in showery weather.—Plants in pots that are set out-of-doors frequently suffer more in showery weather from lack

at times, even in showery weather, for moisture is the very life of plants, and no matter how well the other items of culture may be carried out, any defect in the water supply will defeat the success of all. Wall trees need careful supervision in this respect, as the walls ward off a good deal of the rainfall, and borders are sometimes raised so much above the general level of the garden that a heavy downpour runs away into the low-lying parts, leaving the roots of the trees still dry. Only careful examination will detect these frequent causes of failure.

Zonal *Pelargoniums*.—These plants are very often seen grown in such quantities as to exclude things that are more varied and interesting. When massed together in a greenhouse in large numbers in summer,

the idea that presents itself is that the display is only another phase of bedding which may be done as well out-of-doors. The season most appropriate for these flowers is in winter, when there are comparatively few plants in bloom, and when their flowers are useful for cutting. Market growers strike their plants late, having them much smaller at the end of summer than is usual in private places; but their houses are so constructed that the plants are close to the glass; this enables them to flower freely under a comparatively high temperature. If an attempt were made to bloom plants on this method in the badly-lighted houses often met with in private gardens, they would grow more to leaf than flower. It is, therefore, safer to depend upon older plants that have their wood hard and matured. These may consist of cuttings struck last autumn, or older examples that have been cut back. They should now be standing out-of-doors in a moderately open situation, giving sufficient water to keep them healthy and the growth moving slowly. They ought to be rather under than over-potted, and manurial stimulants should be given sparingly. Prepared in this way the plants will give double the amount of bloom when placed in heat than those having their growth insufficiently matured will do. The large-flowering varieties are liked by some; but the most suitable sorts are those that bloom most profusely, and have the individual flowers comparatively small.—T.

Coleus thyrsoideus.—A good batch of this was moved into 5-inch pots during the week. Last spring a number of plants was used in the greenhouse—ordinarily they are grown in the stove—and did remarkably well under the treatment accorded to a mixed collection of greenhouse plants. Bearing this in mind more cuttings than usual were put in, and in the absence of bulbs it is expected that they will again be useful in the spring. *C. thyrsoideus* is of a rather ungainly habit, and frequent pinchings are necessary in order to obtain bushy plants. Pinching, however, must cease at the end of July, for if the shoots be stopped after that time the growths are liable to be weak and spindly, carrying but indifferent spikes.—KIRK.

Plant-houses continue to be attractive. More use than usual has been made of brightly-coloured Coleuses, which, interspersed with Ferns, are showy. Zonal Pelargoniums and double-flowered Begonias yet remain in good condition, and will prolong the display with a little reinforcing until the time arrives for housing the Chrysanthemums and staging the winter-blooming plants. A useful roof plant is the climbing Fern (*Lygodium scandens*), which in its own way is as useful as Smilax.

GARDEN PESTS AND FRIENDS.

BROWN FRUIT ROT.

APPLES, Pears, and Plums throughout the country are badly attacked this year by the fungus known as brown fruit rot, which, according to Masee, is *Sclerotinia fructigena*, "undoubtedly the most destructive and widely distributed of fungus parasites attacking fruit of all kinds belonging to the order Rosaceæ." It attacks Apples, Pears, Plums, Cherries, and Peaches, and is even found on wild fruits such as the Bullace, Crab, etc. It first appears as a little brown patch on the fruit, quickly spreading until in a few days the whole fruit is brown and rotten. Numerous tufts of white or pale brown warts, really clusters of spores, grow out of the skin in more or less concentric circles. Finally the whole fruit becomes dry or mummified, and often remains on the tree in this condition throughout the winter. The fungus is said to first attack leaves, young shoots, and even flowers,

causing thin dark olive-green patches to form on the surface, from which spores are produced, and these infect the fruits. It is important that all fruit attacked by this disease should be at once collected and either burnt or deeply buried, and as the spores pass the winter in the bark of dead or cankered twigs these also should be carefully cut off and burnt before spring. Masee also recommends drenching the trees and the soil about them in winter with a solution of sulphate of copper, and spraying with a dilute solution of Bordeaux mixture when the leaves are unfolding in spring. It has been suggested that the fungus gets access to the fruit through punctures made by insects, and for that reason an insecticide, such as Paris green, should be helpful as a preventive.

The Board of Agriculture, in Leaflet No. 86, recommends drenching the trees and soil with a solution of sulphate of iron, prepared as follows:—Sulphate of iron, 25 lb.; sulphuric acid, 1 pint; water, 50 gallons. Pour the sulphuric acid upon the sulphate of iron, then add the 50 gallons of water by degrees. A barrel is the best vessel to use; a metal vessel must not be used, as it would be acted upon by the sulphuric acid. Spraying with the above solution should be done in January or February, before the leaf-buds begin to swell, otherwise the foliage and blossom will be destroyed. When the leaf-buds are expanding, and at intervals as required, the trees should be sprayed with quite weak Bordeaux mixture. The above line of treatment must be followed for at least two seasons.—*The Field*.

Romneya leaves injured.—I enclose a few leaves of a very fine *Romneya* which grows freely and flowers every year in my garden, but the leaves of which are, every one, perforated as the specimens I enclose. This has been the same every year. What would you advise me to do? To cut it down and disinfect? And with what? It had brown spots, but "Anti-pest" has cured that.

[The leaves of your *Romneya* have been attacked by one of the shot-hole fungi, probably a species of *Cercospora*. Pick off and burn all the infected leaves, gathering up as well any that have fallen. Then spray the plant with Bordeaux mixture or the following:—Mix $\frac{1}{2}$ oz. of carbonate of copper, 2½ oz. carbonate of ammonia, dissolve them in about 1 pint of hot water. When thoroughly dissolved stir well into eight gallons of cold water. When the leaves have fallen skim off about 1 inch in depth of the surface soil and replace it with fresh. Burn or bury the soil which has been removed some 9 inches below the surface.]

Caterpillars injuring Roses.—I would be obliged for any information re enclosed caterpillars, which have been attacking my pot Roses. This is the first time they have been seen here. The Roses have been out-of-doors some time.—**INQUIRER**.

[By the time the caterpillars reached us they were no longer in the caterpillar stage, but had become chrysalids. They were probably the caterpillars of the lackey moth, which often feeds on Roses. The moth lays its eggs so as to form a bracelet round the twigs of the Roses, and these should be searched for during the pruning in the spring, removed, and burned. For these and all caterpillars on Roses, if there are too many for hand-picking to cope with, there is no better remedy than spraying with lead arsenate, which can be purchased in the paste form and mixed at the rate of 1 lb. to 15 gallons of water—enough to do seventy-five to 100 climbing Roses and a proportionately greater number of dwarfs, and applied with a garden syringe with a fine nozzle.]

THE WEEK'S WORK.

OPEN-AIR GARDENING.

IN BLOOM SEPTEMBER 6TH.—*Catalpa japonica*, *Buddleias*, *Hardy Fuchsias* (in variety), *Calycanthus floridus*, *Sambucus canadensis*, *Spartium junceum*, *Rhus* (in variety), *Polygonum baldschuanicum*, *Clematises*, *Roses*, *Solanum jasminoides*, *Desmodium penduliflorum*, *Wistarias*, *Jasminum officinale affine*, *J. primulinum*, *Indigofera Gerardiana*, *Hydrangeas*, *Hypericums*, *Ceanothus* (in variety), *Olearia Haasti*, *Esculus parviflora*, *Viburnum Tinus*, *Veronicas* (in great variety), *Cistus* (in variety), *Nandina domestica*, *Aloysia citrodora*, *Polygonums* (in variety), *Gyneriums* (*Pampas Grass*), *Lythrum roseum*, *Lysimachia clethroides*, *Sagittaria*, *Nymphæas* (in variety), *Cyperus longus*, *Astilbes* (in variety), *Tritomas* (in variety), *Hyacinthus candicans*, *Gladiolus* (in variety), *Cimicifuga racemosa*, *Liliums* (various), *African Lily*, *Montbretias*, *Yuccas*, *Tropæolum speciosum*, *Lobelia cardinalis*, *Vaccinium*, *Vitis Idæa*, *Romneya Coulteri*, *Asters* (*Michaelmas Daisies*) (in variety), *Delphiniums*, *Hollyhocks*, *Morina longifolia*, *Echinops*, *Helichrysums*, *Erigerons*, *Heleniums*, *Rudbeckias*, *Lavateras*, *Anemone japonica* (in variety), *Enotheras* (in variety), *Acanthus*, *Sidalceas*, *Coreopsis grandiflora*, *Funkias*, *Thalictrums*, *Phloxes* (in variety), *Achilleas*, *Geums*, *Potentillas*, *Linarias*, *Linums*, *Verbena venosa*, *Agrostemmas*, *Statice* (in variety), *Francoa*, *Androsaces*, *Ethionema* (in variety), *Dryas octopetala*, *Scabiosa Parnassi*, *Platystemon californicum*, *Cyclamen hederacifolium*, *Colchicums*, *Sedums*, *Mesembryanthemums*, *Annual Dianthus* (in variety), *Phlox Drummondii*, *Nemesias* (in variety), *Salpiglossis*, *Cosmos*, *Nigellas*, *Mignonette*, *Godetias*, *Annual Delphiniums*, *Stocks* (in variety), *Antirrhinums* (in variety), *Pentstemon* (in variety), *Scabious* (in variety), *Sweet Sultan*, *Cannas*, *Begonias*, *Tufted Pansies* (in variety), *Gazania splendens*, *Carnations* (in variety), *Early-flowering Chrysanthemums* (in variety).

WORK OF THE WEEK.—The weather during the past week has been very unsettled, and 2 inches of rain have fallen since writing my last notes. Advantage was taken of a wet day to turn out of pots and boxes and sort over a quantity of bulbs that were forced last season. These have been planted in the Grass, throwing them into irregular groups, and putting them in with a light digger or mattock. This is better than using a bar, as the soil gets well loosened when the bulbs are put in. Preparations have been made for sowing hardy annuals for early flowering next year. There is a great difference in the stamina and continuous flowering of hardy annuals raised from seeds in the autumn and those which are sown in the autumn. Among others which may now be sown in soils of a poor and rather dry nature are *Antirrhinums*, *Asperula azurea setosa*, *Bartonia aurea*, *Eschscholtzia*, *Linarias*, *Matthiola bicornis*, and *Saponarias*; for ordinary garden soils, *Calliopsis*, *Candytuft*, *annual Chrysanthemums*, *Clarkia*, *Eutocia viscida*, *Erysimum*, *Lavatera*, *Larkspur*, *Linums*, *Lupinus*, *Amaranthus caudatus*, *Malope*, and *Nemophila*. For many of these latter the site should be well prepared by digging in a quantity of well-decayed manure, for the ordinary contents of the mixed border soon rob the soil, and these plants are generally sown to fill up gaps made by things which have had to be pulled up after flowering themselves to death. Each little plot should be well dug and watered thoroughly if dry before, sowing the seeds rather thickly to allow for losses by slugs, etc. The seedlings must not be allowed to remain too thick, thinning them gradually until they have got beyond the size liable to attacks.

TUFTED PANSIES.—Plenty of good cuttings is now available from plants cut back for the purpose. These are now being taken and inserted in a cold-frame previously made up with sandy soil. The frame will be shaded on bright days, and the cuttings sprayed over in the afternoon on fine days. It is useless trying to strike the stout cuttings, the stems

of which are hollow, as roots will not form from these, the only good cuttings being those which are quite solid throughout and small.

F. W. GALLOP.

Lilford Hall, Oundle, Northants.

SOUTHERN COUNTIES.

Orchard-house trees.—Trees that require a shift into larger pots or tubs, or which need repotting, should, if the fruit has been gathered, have attention. To get this done while the trees are still clothed with foliage is a great consideration, seeing that not only are new roots emitted and the fresh compost partially taken possession of by them before the fall of the leaf, but they, as a result, are much better fitted to undergo the ordeal of forcing than when such operations are deferred till later in the season. The receptacles, whether pots or tubs, must be clean and well drained. The compost should consist of the best fibrous loam obtainable, the only additions necessary in such case being a little fine lime-rubble, and a dash of bone-meal and wood ashes. Loams of poor quality may be enriched with a fair proportion of well-decayed manure, which has been dried under cover to get rid of worms. In the case of repotting only, as much of the old compost as possible should be picked out from between the roots all over the balls, and the roots found in the surface mulch and amongst the drainage material must be sacrificed to make way for the new. The potting must be thoroughly well done, making the compost as firm as possible with the aid of a potting-stick.

Winter-flowering Carnations.—Plants intended for this purpose and which have been in pits and frames for the past three or four months now need to be staked and tied and taken into the house in which they are to bloom. If the pots are well filled with roots a sprinkling of Carnation manure will prove beneficial. Plants which have been flowering more or less since last autumn may be induced to yield a still further supply of bloom if cleaned over, relieved of useless growths, and top-dressed with suitable compost containing a little Carnation manure.

Malmaison Carnations.—The layers being well rooted must now be repotted. Three-inch and 4-inch pots, according to the size of the plants, are large enough, and until the roots get to work in the compost the frame or pit in which they are stood should be shaded and kept fairly close. Old plants recently potted should now be given a position in a house where they will have an abundance of light and air. To keep the growth sturdy there must be plenty of space between the pots on the stage.

Border Carnations.—Unless found by actual experience to winter well outdoors, the rooted layers are best taken up, potted at once, and stood in cold-frames or pits, where they can be protected when necessary. On all other occasions, wet weather excepted, they should be freely exposed.

Callas.—Where the practice of planting out after the flowering season is over obtains, the crowns should now be lifted and potted. After such a summer, it is doubtful if these will afford such satisfactory results as will crowns which have been kept in pots and stood in full sun to get thoroughly ripened. Callas do best in a compost consisting almost entirely of loam, the only additions necessary being a little rough leaf-mould and lime-rubble to prevent it, if of a heavy nature, becoming too retentive. A vinery in which the Vines are at rest is a good place to stand the plants in after they are potted.

Achimenes and Gloxinias.—These, as they pass out of flower, should be removed to a pit or frame and kept quite cool, so that they may gradually go to rest. The water supply must be reduced by degrees as the foliage and stems are noticed to be ripening off. The same remarks apply to Caladiums.

Libonia floribunda.—Plants intended for autumn display should now be moved into the greenhouse after vaporising them if there is any fly present. Water carefully for a few days, as the change oftentimes causes loss of

foliage. Afterwards, or until the plants come into full bloom, weak liquid-manure may be given.

Lorraine Begonias.—Plants of the various types of this useful winter-flowering Begonia are now growing freely and require attention in the way of training. For general purposes one stake to each plant to which the growths can be looped up suffices, but if large-sized, round-headed, rather than pyramidal-shaped plants are required, then from four to five stakes are needed round the outside as well as one in the centre. To have this Begonia at its best the young plants should be grown in an intermediate temperature in a house by themselves.

Heliotropes.—For autumn and winter flowering these, where scented flowering plants are appreciated, are much prized. After a continuous suppression of flowers and pinching and repinching of growths to obtain bushy plants, the time has now arrived when the forwardst may be allowed to bloom. To ensure fine trusses of bloom give an occasional dose of Clay's fertiliser, which should be sprinkled on the surface and watered in. Specimen plants, with bare stems, about 18 inches in height, and pyramidal-shaped heads some 15 inches through in the widest part, are also very useful for house decoration.

Clerodendron fallax.—Plants now coming into bloom should, to extend the blooming period as far as possible, be moved to the warmest part of the show-house and where they will not be subjected to cold draughts.

Calanthes.—These, having made an abundance of roots, should be assisted with mild doses of stimulants when water is required, which will assist in the building up of bold pseudo-bulbs, which, in turn, will yield vigorous flower-stems and inflorescences in due course.

Flower garden.—As the different types of Rambler Roses pass out of bloom they should be relieved of the oldest of the wood to make way for the current season's growths, which should be lightly tied to the trellis or arch on which they are trained. Roses in beds need looking to every few days, picking off faded blooms and spudding the suckers as they push up. Flower beds require looking over frequently, when dead flowers and decaying foliage must be picked off, and all kept as tidy as possible. Specimen plants in tubs and pots of Zonal, Ivy-leaf, and Scented-leaved Pelargoniums, Myrtles, Fuchsias, and early-flowering Chrysanthemums must not only be kept well watered, but fed with stimulants also. A mulch of old Mushroom manure passed through a ½-inch sieve is much appreciated by all the foregoing.

A. W.

MIDLAND COUNTIES.

Morello Cherries.—The crop, which has been a good one, having been gathered, the trees will now be given the necessary pruning. It is wiser to prune the trees now than wait until the leaves have fallen, as the operator will be better able to decide while the foliage is still on the trees which shoots can best be spared. Another advantage is that the young shoots are more likely to be allowed a proper distance apart and the danger of overcrowding avoided, also more light and air will reach the remaining wood, thus enabling it to ripen more thoroughly. The Morello Cherry requires to be pruned quite differently from the Sweet Cherry, the method being similar to that for Peaches and Nectarines. All useless and old fruiting wood should be cut out so as to allow room for training in some of the young shoots, as these will produce the best fruits next season. After the necessary pruning has been completed the trees should be given a good syringing with an insecticide to cleanse them of any insect pests that may be present on the foliage.

Apples and Pears are ripening rapidly, and the gathering of these will now require almost daily attention. Dry days must always be chosen for the gathering of all kinds of fruit, and when taken in they should be carefully sorted, otherwise imperfect and bruised samples, which cannot be expected to keep, will soon rot and destroy many of the good

ones. The fruit-room has been thoroughly cleansed and made ready for storing the fruit.

Begonia Gloire de Lorraine and varieties. —Late-rooted plants of this Begonia should now receive all the encouragement possible, as growth made after the month of September is too late to produce a satisfactory crop of flowers. Pinch off the flower-buds once more from those plants intended to bloom in October and November. Allow them plenty of room, overcrowding always resulting in inferior quality. Keep the shoots tied up to neat stakes, but avoid using more stakes to a plant than are necessary, as over-staked plants have a stiff and objectionable appearance.

Housing plants must now receive attention, as it is not safe in this locality to trust anything of a tender nature in the open air after the middle of September, for, though the night temperature may not fall so low as to permanently injure the plants, a few degrees below freezing point often give the foliage an unsightly appearance from which it does not recover. Previous to housing the plants, it is usual to give the glass and woodwork a thorough cleansing with soft soap and water, but owing to shortage of labour this season all we are able to do is to wash down with the hose-pipe.

Brussels Sprouts.—A few of the old leaves at the base of the plants should be taken off to allow a free circulation of air and light, particularly where much growth has been made and the leaves are now thick together. If this work is neglected the young Sprouts will become drawn, weakly, and loose.

Celery.—See to the earthing up of this at the first favourable opportunity, but never on any account do it when the leaves or stems are damp, or decay of the crowns is sure to take place.

Cauliflowers.—The second sowing of Cauliflower seeds will now be made on a warm border, sowing the seeds thinly in shallow drills. As soon as the seedlings are large enough they will be transplanted to cold frames, using soil of not too rich a nature. The chief aim is to procure sturdy plants; therefore, whenever possible the fullest amount of air should be given, even in winter. The sowing of Cauliflowers during September and wintering the plants in cold frames are not nearly so much practised now as formerly, owing to the numbers of new varieties that may be raised in heat during the early spring and quickly forced. The results from autumn-sown plants are infinitely better than those from plants raised in spring.

Cabbage.—The principal batch of Cabbage intended to furnish a supply in spring must be planted without delay on land which has been well prepared. The surface of the ground should be broken down finely and a good dressing of soot and wood-ashes applied. Allow a distance of 18 inches or 2 feet between the rows, according to the variety, and 1 foot from plant to plant. Every alternate Cabbage can then be cut when quite young. I always plant a small number of the largest plants on a south border, these coming in useful for cutting very early, as compared with those on the principal break. Continue to hoe as frequently as possible the surface soil between all winter crops. The season of growth is now becoming very short, therefore every assistance should be given to the various crops so that they may become properly matured and be, therefore, the better able to withstand severe weather in winter.

F. W. G.

SCOTLAND.

Vegetable garden.—During the week second early Potatoes, now quite ripe, were lifted and stored. The crop is good and even, and if there are no specially large tubers, there is, on the other hand, a gratifying absence of very small ones. Disease is practically non-existent, only two tubers which were slightly affected having been noticed. It is unwise, I think, to store these Potatoes in a heap if such a method can be avoided. There is a tendency to heating, which is against the Potatoes keeping well. It is better, therefore,

to place them thinly in the store, which at this time of the year must be freely ventilated. Autumn Onions have germinated well, and the hoe was run lightly through the lines. As soon as the growth of the Onions permits, weeds will be carefully hand-picked from among the plants, and this clean-up will probably keep the quarter clean until spring. Peas, about which some doubts were for a time entertained, have turned out most satisfactorily. As soon as possible after picking any given line is finished the straw is cleaned off, and, if dry enough, burned. Otherwise, it is removed to the rot-heap, for if allowed to lie in a heap it is apt to form a very convenient lurking-place for insects. Only a few lines of Peas are grown upon stakes, wire being used in the majority of cases. Contrary to the usually expressed opinion, I find that Peas do quite well upon wide-meshed wire-netting, which is easily put up, easily removed, if a little tedious to clean, and, if well looked after, practically indestructible. Surplus French Beans continue to be regularly picked for preserving for winter use. Spinach and Spinach Beet have evidently been suited by the weather, both being available in quantity. Onions planted in spring from last autumn's sowing have now been pulled and laid out thinly to dry. The stems of hulbs from seedlings raised in heat during the present spring were twisted over to hasten ripening. Sown-out Onions are moderately good, and as growth will continue for some little time yet, they have been cleaned down. Hand-weeding and thinning were attended to in the case of late-sown Parsley. Cauliflowers, on the whole, have been very disappointing, the mid-season varieties having been practically a failure. This matters the less at present as there is an abundance of other vegetables, and it is hoped that the autumn varieties will give a better account of themselves. More Cahages were put out into nursery beds for planting at a later date.

Figs in pots.—A very useful second crop is being assisted by the application of frequent doses of weak liquid manure. To finish the fruits it may yet be needful to give them a rather warmer temperature. Up till now the trees have been grown without the aid of artificial heat, and both wood and foliage are robust. A little top-dressing was afforded to the trees in the course of the week.

Peaches and Nectarines out of doors.—In the case of Peaches the date of ripening is, roughly speaking, a fortnight later than is customary. As usual, Hale's Early was first, and will be followed by Stirling Castle and Dymond. The crops are moderate, but not heavy. In respect of Nectarines, the crop, more precarious on south walls than Peaches, is decidedly heavier, but will be later by a week. The trees in both cases were again looked over during the week, shoots tied in, and the fruits exposed to the sun by the removal of superfluous or obtrusive foliage. Time was found to give all the Peach and Nectarine trees a good soaking of liquid manure. This is the last application which they will receive so far as stimulants are concerned.

Pears.—In order to hasten these along, the trees were, at the same time, given a good allowance of the same liquid. The crop is, on the whole, better than looked likely at one time, although, perhaps, individual fruits, generally speaking, will not be so large as usual. Yet there are some. Benrre Giffard for example, upon which the individual fruits are of a superior size. Lateness in maturing, all over, will be the rule.

Plums.—Shoots which have grown since summer pruning was done were again pinched back, and, as in the case of Peaches, such foliage as was interfering with the fruits is, as opportunity offers, being reduced.

Flower beds.—The out-and-in character of the season has been adverse to the plants, but the display is now fairly satisfactory. Beds of the Swan River Daisy, through which rises one of the taller blue Larkspurs, are quite good. A bed filled with Ageratum and the same Larkspur and edged with Lobelia has filled out capably. I think that, on the whole, Ageratum is more satisfactory for summer bedding than is Heliotrope. I saw some beds of the latter recently, which, owing no doubt to the

cold weather experienced after planting, are an entire failure. Further, Heliotrope succumbs to a trifling frost comparatively early in the season, while Ageratum is much more hardy. The latter is, by some, propagated from cuttings, but this is quite unnecessary, for a packet of seed sown in early March will provide strong plants which are ready for putting out at the end of May, and which bloom equally as well as those from cuttings.

Ferns for cutting.—Fronds of Adiantums are always in request for cutting during the winter. Plants, therefore, intended to provide material for this purpose ought now to be grown as coolly as possible and given abundant ventilation, with a free exposure to light. Grown under such conditions the fronds are robust and the foot-stalks firm and hard. If Ferns are grown in a humid, rather high temperature it is idle to expect that fronds will last any length of time when cut for the purpose referred to. A little weak soot-water, occasionally, keeps them of good colour.

Plant-houses.—With the advancing season a little re-arranging from time to time is of service. Withered blooms and foliage must be regularly removed, especially in the case of such things as Zonal Pelargoniums, which are liable to be affected by damp. Begonias of all kinds, including B. Weltoniensis, yet remain in good order, and will prolong the display until it is necessary to house the earliest Chrysanthemums. In the stove, Gloxinias remain bright, and the earliest Gesneras begin to show the spikes. Some of these will be permitted to bloom, but the majority of the spikes will be pinched out. In this house it is now necessary to run a little heat through the pipes, but, for the present, a very moderate allowance suffices if early closing is practised. Watering is now much less insistent, although it must be by no means neglected. Syringing is done once a day, in the early afternoon, and only in bright weather. In the stove a night temperature of round about 70 degs. is easily kept up with very quiet firing, and if the thermometer indicates 65 degs. in the morning such a temperature is high enough for most things at present. W. MCGUFFOG.

Balmie Gardens, Kirkeudbright.

OBITUARY.

MR. D. E. THOMAS.

It is with deep regret we have to announce the death of Mr. D. E. Thomas, at the age of 55, on Saturday, September 2nd. He had been connected with "Farm and Home" for nearly thirty years. In the farming world he was well known, being a member of The Farmers' Club, while in the horticultural world many of his acquaintances will be sorry to hear of his death at a comparatively early age. Mr. Thomas was born in Carmarthen, and at an early age worked as a printer, this experience standing him in good stead later in life, when he took up journalistic work. After giving up the practical side, we understand he joined the *Bath Chronicle* as chief reporter, leaving this at an early age to edit a paper in his native town. Eventually he found his way to London, where, after a varied experience in journalistic work, he joined the staff of "Farm and Home." Never enjoying robust health, he was always cheerful and uncomplaining, and did not spare himself. He was, in the words of one who knew him well, "one of those anxious workers who always put work and duty first."

Having been brought into contact with him day in and day out for over thirty years, I have had every opportunity of seeing the interest he took in his work and his sterling worth. He was always ready to help with his advice in any difficulty, and it pains me to find that a confrère of so kindly a nature and so modest withal is no more. He leaves a widow and two sons, both of whom are now in the Army, to mourn his all-too-early death. W. P. T.

CORRESPONDENCE.

Questions.—Queries and answers are inserted in GARDENING free of charge if correspondents follow these rules: All communications should be clearly written on one side of the paper only, and addressed to the EDITOR of GARDENING, 63, Lincoln's Inn Fields, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent each should be on a separate piece of paper, the name and address being added to each. As GARDENING has to be sent to press some days in advance of date, queries cannot always be replied to in the issue immediately following their receipt. We do not reply to queries by post.

Naming plants.—All who wish their plants to be rightly named should send fair examples of each—the stem, leaf, flower, or fruit. (Snippets of leaves and points of shoots are useless.) Not more than four plants should be sent in any one week by the same correspondent. Where more than one kind is sent they should be numbered. Of conifers the fruit should always be sent.

Naming fruit.—Several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruits for naming, these in many cases being unripe and otherwise poor. We can undertake to name only four varieties at a time.

PLANTS AND FLOWERS.

Ehretia serrata (V. M.) comes from the East Indies and is generally treated as a stove or greenhouse evergreen tree or shrub. The flowers are white, small, numerous, and have a powerful honey-like perfume. It is said to grow to a height of 6 feet.

Azalea leaves turning brown (A.).—The leaves are covered with "thrips." Lay the plants on their sides and well syringe them with strong Tobacco-water. Place them afterwards in a partially-shaded situation out-of-doors, setting them on elates to prevent the worms entering the pots. Syringe them freely every afternoon with clean soft water, and repeat the Tobacco-water washing (placing the plants on their sides) twice a week for two or three weeks.

Tuberous Begonias as basket plants (F.).—Yes, these do make capital basket plants, and there are now very many excellent kinds to be had; and if treated in this manner, and well managed, the large, brilliantly coloured blossoms, which are naturally of a drooping character, can be seen to advantage. They should be grown in good soil and kept well supplied with water, and if placed in a moderately cool, dry house they will produce a charming display of flowers for months in succession.

The Throat-wort (*Trachelium cœruleum*) (A. B.).—This is the name of the plant you send. It is easily propagated in the spring from cuttings taken from the base close to the soil, some of these possibly having roots of their own. Such plants will flower the same season in 6-inch pots, being afterwards kept to grow on the following spring, so as to provide, if need be, a set of larger plants. Seedlings can also be easily raised, but when this plan is adopted the seed should be saved and sown as soon as it is ripe from plants that have flowered early in August. The seedlings can then be kept in a box or pan in a cool greenhouse during the winter. This plant will do good service at a season when any novelty is a pleasing change. The best trusses of violet-blue flowers are produced on the terminals, but the lateral shoots on strong plants are also very effective. The best soil is loam and leaf-mould, with a little sand, potting being done very firmly.

TREES AND SHRUBS.

Magnolia grandiflora not blooming (R. R. N.).—A very probable cause, due in great measure to the poor sandy soil in which the plant is growing, is dryness at the roots. We should advise you to give it a heavy mulching

of rotten manure and water freely. If you do this and get well ripened wood, you will, we think, find that your plants will flower in due course.

Pruning the Oleander (C.).—The Oleander is naturally of a loose, Willow-like style of growth, so that any attempt to keep it dwarf will result in the production of few, if any, blossoms, and, generally speaking, the more pruning the fewer flowers. Still, if the plant is not showing flower, it may be cut back to within a couple of feet of the pot at once, or, if there are any blossoms, as soon as they are past. Good, stout growths are very necessary for flowering, hence, in cutting back, any weak and exhausted shoots may be removed altogether. If you cut your plant back now you must not be surprised at a poor floral display next year.

Campanula glomerata (C.).—The plant of which you send flowers is *Campanula glomerata*, a hardy border perennial growing about 18 inches high, and producing its violet-purple flowers in clustered heads on the top of the stems, and sometimes also in axillary clusters in the uppermost parts of the stem. The plant may be raised from seeds, though a better way of obtaining a quick return would be by the purchase of a half-dozen plants from any of the hardy plant nurserymen. The plants may be had for about 6d. each. It is not only quite hardy, but grows freely in any ordinary garden soil. The plant may be increased by dividing the roots in early spring. There is a large-flowered kind known as *C. g. speciosa*. This is a rather stronger grower.

FRUIT.

Treatment of Raspberries (E.).—You may cut away the old fruiting canes on your Raspberry stools at once. In future, cut them away as soon as they have done fruiting, as then more room is given for the young canes to grow and ripen. If your stools are a few feet apart in rows, the usual course is to allow about five stout canes or six weaker ones to remain for the following year's fruiting, cutting out all the rest. Do that now, also as many small canes or suckers, only do not injure those it is desired to save. When that is done, it is well, unless you can give the surface some manure, to allow the breadths to remain until the leaves have fallen, then to tie up the canes to stakes loosely, and give the soil a dressing of manure or decayed garden-refuse.

Grapes shanking (R. H. Butler).—From what you say and without our seeing the Grapes you refer to, your Grapes are what is known as "shanked," a term applied to denote the withering up of the stalks and berries of the Grapes, as is happening in the case of those you refer to. Sometimes only a few berries shank, in other cases the whole bunch, and in bad cases the entire crop. The berries thus affected never ripen, and soon decay. Many reasons have been given for this disease, among others overcropping. If the roots get into a bad subsoil shanking is sure to follow, while a sour and sodden border will also cause it. If the roots have gone down into a bad subsoil, then the only remedy is to lift the Vines and replant them, affording good drainage if the position is low, and making the border of good porous soil, so that the roots can run freely. We should advise you to procure a copy of "Vines and Vine Culture," which can be had from this office, post free, for 5s. 6d.

Summer pruning Currants, etc. (Anon.).—Black Currants may be freed from any straggling growths or somewhat shortened back, but not close pruned. They fruit on the new wood of the previous year, so a fair portion of such wood must always be left to produce the crop. Red Currants require the opposite treatment as they fruit mostly on spurs. Plums may now be pruned, cutting back what is termed foreright shoots—i.e., those produced in front of main branches, but laying in side shoots if on a wall; if otherwise, multi-pruning is not desirable unless trees are overcrowded. Prune later on early in autumn or early winter, at that season cutting lateral or side growths back to a few buds, leaving only main shoots to form branches or extend, these latter being shortened. Damsons should not be pruned at this season, and not much even in the winter,

unless crowded, merely removing cross branches or weak, crowded wood to let in sun and air to ripen the wood and facilitate gathering of the fruit.

VEGETABLES.

Peas falling (P.).—Your Peas are covered with thrips and red-spider, caused by excessive drought, and moisture in abundance is the only remedy. Your soil is probably light and none too rich. In dry seasons the plants should be sown in deep drills, and the sides of each row mulched with manure if the weather be hot and dry.

Caterpillars on Cabbages (Percy W. Cross).—Hand-picking is the best remedy, but if caterpillars are too numerous syringe the Cabbage plants with warm, mildly salt water, and soon after give a heavy washing with clear water. Dustings of fine salt overnight, washed off with clear water the next morning, often do very much to destroy the caterpillars.

Tomatoes cracking (Amateur).—The cracking of fruit of any kind when ripening is generally due to an excess of moisture in the soil when the crop is finishing. In some cases this may have been brought into greater prominence by previous dryness causing a tightness of the skin. It is good practice to give Tomatoes in pots or in boxes a good top-dressing just when the fruits begin to ripen. This enables the plants to finish off the fruit properly without any special aid from the water-pot beyond what is requisite for the well-being of the plants.

Tomatoes damping off (A Grower).—You keep the Tomatoes too moist, the atmosphere too close, and you have given too much manure. How can plants absorb bone-meal, then a good dressing of cow-manure, finally, liquid-manure, all in a short time? You have been far too good to them; either one or other of the manures would have been sufficient. You say they did well till the manure was applied. You should remember cow-manure is moisture-holding, and your plants cannot do with the surface roots completely smothered up and watered as yours have been.

Tomatoes scalded (Starter).—The fruits sent are what is known as scalded, which is caused when in the morning the fruits are damp with moisture because the house has been shut up close, and the sun coming out brightly has scalded them before they were dry. Scalding, too, is often caused by the stupid plan of cutting away the foliage. Rich food is given in excess to the plants, with the result that, there being no foliage to absorb such food, it is forced into the fruits, causing bad flavour, spot, and scalding. We do not denude other plants of their leaves in the same way as one often sees Tomatoes treated, and when this severe removal of the foliage is carried out little wonder is it that scalding ensues. The smooth varieties of Tomato are more liable to scalding than the corrugated sorts, probably due to the skin being more sensitive.

Cabbages and Brussels Sprouts clubbing (C. C. and T. E. Wild).—The best remedy for clubbing, from which you say your Cabbages, etc., are suffering, is gas-lime. That should be applied to vacant ground in the autumn, at the rate of 2 bushels to 3 rods, if clubbing is very bad. If it be not, then put 1 bushel to 2 rods of ground. After lying on the ground from four to six weeks, dig the dressing in. Even a dressing at the same rate of fresh lime is good also. Rather than plant any of the Cabbage tribe, plant Potatoes, Sea-kale, or Rhubarb, or sow Onions, Parsnips, or Beet—indeed, anything other than Cabbage. By doing so for a couple of years the club trouble may disappear. Peas or Beans also may be sown with advantage. Of course, you must understand that ground dressed with gas-lime cannot be cropped for three months after the dressing has been applied.

SHORT REPLIES.

Failure.—It is very difficult without seeing one of your plants to hazard a guess as to what is the cause of failure. We should say from your description that your Cabbages, etc., are suffering from the disease known as "clubbing." If you lift one of the plants you can soon settle the question. See above.

NAMES OF PLANTS AND FRUITS.

Names of plants.—*A. B. Flower.*—We cannot undertake to name florist flowers.—*A. Boy.*—Dog's Mercury (*Mercurialis perennis*). The only way is to trench the ground and clear the roots out as the work proceeds.—*J. N. B.—1,* the Salt tree (*Halimodendron argenteum*); 2, *Gnaphalium angustifolium.*—*Eleanor Pain.*—*Hibiscus syriacus* *Bleu Coeleste.*—*E. Clarke.*—Please send specimen of the white Echinops you refer to.

Bulb growers will oblige by sending early copies of their Lists and Catalogues to MANAGER, "Gardening Illustrated," 63, Lincoln's Inn Fields, London, W.C.

Guaranteed British Bulbs.

Free carriage and packing will be given to all orders of 10s. value when cash is sent with order. Smaller orders should have 6d. extra enclosed.

BAYLISS, JONES & BAYLISS, Ltd.
WOLVERHAMPTON AND LONDON

WANTED AT ONCE as Head Gardener for large garden and grounds of Dr. Barnardo's Home, married man; thorough all-round experience; able direct staff as trainer. Wages to be arranged. Apply in writing, with references—GOVERNOR, Village Home, Barking-side, Essex.

HEAD GARDENER WANTED by the Hon. Robert C. Devereux. Must be good all-round man. Cottage found. Apply—PENRY LLOYD, Estate Offices, Canon Road, Ledbury.

GARDENER WANTED.—Wanted, a Man, exempt from Army Service, for Greenhouses and Garden attached to family residence. Good wages paid to capable man. Applications to—A. NUTTALL, "Northwood," Blackburn.

LADY GARDENER required for Bourne End, Bucks, at end of September (single-handed), with at least two years' experience. Assistance given in mowing and digging. No hot houses, no bedding out. Vegetable garden and Roses. Must have good references. Write, stating wages, to—LADY E. Lligwy, Moelre, Anglesey.

SMALL HOLDINGS.—One or twenty acres of good pasture or arable land, suitable for fruit growing, market gardening, or poultry farming, at Headcorn, Kent, one of the best fruit-growing districts in Kent. The free; main water supply; frontage to main country road; five minutes by motor bus to station. From £25 an acre.—WILKS, 25, Abchurch-lane, E.C.

CLEARANCE SALE

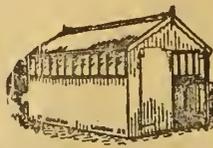

Owing to our Works and Show Grounds being taken over by the War Office, we are offering the remainder of our Stock unsold at Special Low Prices. SEND FOR CATALOGUE.

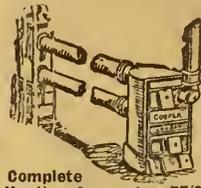

Greenhouses, from £5 5s.

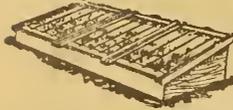

Portable Huts, 57/6.

Motor Car House, £8 12s. 6d.

Complete Heating Apparatus, 77/6

Cucumber Frames, from 21/-

Dog Kennels, with platform, from 15/-

Hardwood Garden Barrow, 27/6.

Poultry Houses, from 35/-

Rustic Houses, from 57/6.

CLEMATIS DISEASE AND ITS CAUSES.

My friend Mr. Morel, of Lyons, has sent me an interesting letter on this subject, of which he has much experience as the raiser of some beautiful kinds. I have thought it better to print his letter as it came to me—in French—lest a mistake should be made in making a translation. One may see in it certain things of importance, such as the mistake of grafting on our English *C. Vitalba*. But the letter mostly concerns grafting, whereas we want to fix people's minds on those that are not grafted. Why should we graft things that are easily raised and increased by layers, as in the case of the Clematis? Except, perhaps, in the case of new things, we can see no reason at all for grafting, and I have a large collection of Clematises, and do not lose any of the plants by disease, or very rarely, and in every case I grow them on their natural roots.

W. R.

MONSIEUR.—J'ai été beaucoup intéressé par votre commentaire sur le travail de Jackmann à propos de la mortalité des Clématites.

En réalité, toutes les causes qui sont mises en avant ne sont que secondaires, quand elles tout même pour une part dans la disparition des plantes. On a aussi invoqué la présence des anguillules sur les racines; or j'ai des plantes qui vivent bien depuis dix ans avec ces anguillules par milliers sur les racines.

La véritable cause de la mort soudaine des Clématites, qui périssent souvent en pleine floraison, me paraît d'origine bactérienne et siège dans un point souvent assez réduit de la tige, plus ou moins haut placé, le plus souvent près du pied, mais aussi parfois à mi-hauteur ou dans le tiers supérieur. A ce point, qui est facile à trouver au moment où l'on voit une plante flétrir, on découvre que l'intérieur du rambeau, quelquefois sur une hauteur de quelques millimètres seulement, est rempli d'une poussière noire provenant de la décomposition des vaisceaux et de la substance ligneuse ou herbacée qu'ils contiennent. Au dessus de ce point la plante est morte, au dessous elle est vivace et repart vigoureusement pour une nouvelle floraison.

Il arrive même quelquefois, lorsque le mal se produit au pied de la plante, que la partie restant au dessus du point attaqué porte quelques racines qui font vivre le haut de la plante, tandis que la

souche repart de son côté, alors on a deux plantes en supprimant le tronçon de tige qui la maladie a détruit.

Quels sont la cause et le traitement de ce mal mystérieux et irrémédiable jusqu'à présent? Personne ne m'a encore répondu d'une façon un peu satisfaisante.

Il semble que les variétés issues de l'hybridation y sont plus sujettes que les espèces typiques. Les *Viticella*, les *florida*, les *lanuginosa* mêmes, en tant qu'espèces types, y échappent à peu près, mais il n'en est plus de même dès que l'on se trouve en présence d'hybrides de ces diverses espèces, ou de variétés dans lesquelles l'hybridation a pu jouer un rôle.

Des moyens préconisés pour éviter ou guérir cette maladie aucun de m'a réussi. Je m'efforce d'obtenir des plantes qui n'y soient pas sujettes.

Les *Viticella*, sous ce rapport, sont privilégiées. Donc en améliorant les *Viticella* en cherchant à enrichir leur coloris et à agrandir leurs fleurs, mais sans hybridation avec des patens ou des *lanuginosa*, on arrive à de très bon résultats.

Les hybrides de *Clematis coccinea* et de *Megalanthes* sont aussi dans une certaine mesure bien plus épargnés, et si quelques tiges périssent ce n'est presque jamais complètement et il en reste assez de vivaces pour continuer le rôle ornemental de la plante.

J'ai déjà constitué pour moi tant une collection de belles variétés rustiques. Je vous en ai envoyé quelques unes. Je vous en enverrai d'autres aussitôt la fin de la guerre.

Malheureusement cette recherche est fort longue. Les graines de Clématites ne germaient que la deuxième année du semis—je parle des *Viticella*. Ce n'est donc qu'après la 4 ou 5 année d'attente qu'on peut voir les fleurs des plantes qu'on a travaillées en vue d'obtentions nouvelles—je parle des *C. Viticella*, *florida*, *patens*, *lanuginosa*. C'est la vie d'un homme qui passe tout entière à des recherches persistantes portant sur plusieurs générations de plantes. Mais c'est très passionnant.

Vous avez raison de blâmer le mode de greffage sur *C. Vitalba*. J'ai souvent remarqué chez les plantes reçues d'Angleterre le fâcheux système dont vous donnez l'image. Mais ce mode est à peu près abandonné, on greffe sur racines de *Viticella*, ce qui donne en somme une bouture qui n'emprunte à son support qu'une aide

passagère pour former elle-même les racines sur lesquelles elle vivra.

Si vous trouviez un micrographe disposé à étudier cette maladie, je pourrais l'année prochaine vous envoyer des tiges atteintes en assez grande quantité pour permettre des recherches suivies et complètes.

NOTES OF THE WEEK.

The Snowdrop Windflower (*Anemone sylvestris*).—This, as usual, is throwing up a few autumn flowers which are particularly welcome now, when the rock garden has none too much blossom. Both the single and double forms are in flower, and both are lovely. It thrives and blooms well in a warm soil and an exposed position.—N. L.

A large Puff Ball.—I have found in my orchard a Puff Ball measuring 2 feet 6 inches round. Is it known what causes them? There was a lot of smaller ones.—C. PHELIPS.

[Fungi are, as a rule, found in soil containing decaying matter or in the wood of dying or dead trees.—ED.]

Single Asters.—The single varieties of Asters are equally as showy as the stiffer doubles when in bloom, and not only are they more useful for cutting, but they are not so readily affected by wet. The heads are carried on stiff and wiry stems, and, associated with *Gypsophila paniculata*, they last for a considerable time in vases. There are now many fine shades of colour among them, and all over single Asters are worthy of more extended culture for the summer flower garden.—Kirk.

Campanula Mayi.—Everyone admires the pure white *Campanula isophylla alba*. This newer form makes a delightful companion to it, the long pendulous shoots being thickly studded with blossoms of a charming porcelain-blue shade. So free-flowering is it that a succession is kept up from one particular plant for some time. It is supposed to be of hybrid origin, with *C. isophylla* as one of its parents, but little seems to be known on that score. The foliage is hoary, and in this respect is very different from that of *C. isophylla*.

Fruit trees and moisture.—There is no doubt that the recent rains have been all against the success of the fruit crop during the present year, but we are apt to overlook the fact that the rain has been

in favour of the trees. In the majority of cases a look round shows that the buds for next year are strong and numerous. There is no doubt that this is due to the roots having been kept comfortably moist throughout the growing season, and if the crops this year have been disappointing there will be, it may be hoped, judging from present appearances, a better return next season.—W. MCG.

Destruction of Bananas.—From the *Jamaica Times* of August 19th we learn that a terrific hurricane has visited the island, with the result that the Banana plantations are ruined, while the Bread Fruits, Mangoes, and Cocoa Nut trees have suffered heavily. There will be no Bananas till 1917, while in some cases there will be but few until 1918, as the larger stems have all been broken down, the only ones left being those that were too short to bend over. It is somewhat strange that in past storms the Bananas were laid low, while this one has broken the plants off in the middle. In addition to the destruction of the various fruits mentioned above, great damage was done to property and shipping.

Floral novelties.—A well-known architect up Westchester way, according to the *Saturday Evening Post*, was standing before one of his newly-completed creations. Its mistress, plentifully sprinkled with diamonds at eleven in the morning, turned to him and said:—"It's grand! And I've just decided not to employ a landscape gardener. I know just what I want myself. Banked up right against the porch there I want a real thick border—now what is that name? You know; those bright-red flowers that look so dressy—yes; now I have it—Saliva!" The architect was staggered for a moment, but soon recovered and came back enthusiastically. "The very thing!" he agreed. "And right in front a nice row of spitunias!"

The Sage-leaved Rock Rose (*Cistus salvifolius*).—The dull, cool season has prolonged the flowering of this beautiful Rock Rose to a much later date than usual. The flowers are not so large as in some of the other kinds of *Cistus*, but they are, to my mind, as beautiful as any, the pure white flowers just flushed with yellow at the base of the petals. It makes a nice shrub for the bolder parts of the rock garden, and I have it growing very satisfactorily on the lower part of a big retaining wall. It grows fairly rapidly, but can be kept well within bounds by judicious cutting back after flowering. Cuttings taken off with a heel in the autumn and planted firmly in sandy soil will be well rooted by the following summer.—N. L.

Roses from cuttings.—Several references have lately been made to these. I find the weaker-growing varieties do not make much headway from cuttings on our heavy soil, but strong growers, like Caroline Testout, make good plants, flowering well. Dwarf varieties with which I have been successful are: Caroline Testout, Mme. A. Chatenay, Frau Karl Druschki, Mme. Ravary, Gruss an Teplitz, Killarney, President Carnot, Mme. E. Metz, Ulrich Brunner, and Duke of Edinburgh. Another Rose which is said to do well in some districts on its own roots is Zephirin Drouhiu. I am testing it in a short length hedge, the plants having been bought in quite small on their own roots three years ago. All have grown, but only about half the plants have thrown up young, vigorous shoots, without which they cannot long continue. A tall-growing Rose that has given much pleasure grown from cuttings is Conrad F. Meyer.—C. TURNER.

Questionable advice.—In a pamphlet entitled "Economy in the Garden," issued by the Royal Horticultural Society, various suggestions for economy in all parts of the garden are made. I was, however, surprised to read the advice contained in one paragraph, namely, "Sow Cabbages and other Brassicas where the plants are to grow and not in seed-beds. The seed will cost more, but the saving of labour will more than repay the cost." The advantages of this plan appear to me very doubtful, as a newly-cleared piece of ground may be planted with Cabbages, whereas, if the seed is only sown when the plot is available, it will be too late in the season to sow the seed. On the merits or demerits of the scheme the opinion of some of your readers with practical experience would doubtless prove interesting.—IN DOUBT.

Cactalia coccinea.—This annual is flowering freely now in our Sheffield garden, its bright orange-scarlet flowers making it very showy indeed. It is an easy thing to grow and comes up freely from seed. I sowed mine indoors in March and planted out at the usual time, and this method is better than sowing out-of-doors. My plants have reached a height of about 1 foot this year. Catalogues say that they should grow up to 18 inches or even more, but perhaps they would have done so in more congenial weather. Any way, this is a very bright little annual, and as the flowers are useful for cutting it will commend itself to many people. In warm districts it could be sown out-of-doors any time now, but in our exposed Sheffield garden we have not attempted autumn sowing of annuals for many years.—E. T. ELLIS, *Weetwood, Ecclesall, Sheffield.*

FRUIT.

THE MORELLO CHERRY.

In some gardens the Morello Cherry is most disappointing, the branches dying away in an apparently inexplicable manner. But even in these cases the grower need not despair, as some means might be found by which the trees may be got to succeed fairly well and successful crops be assured. I think a sluggish root-action is answerable for most of the failures. To this and hard winter pruning, or the two combined, may be fairly traced the downward course of many trees. With others it is the want of suitable food, the yellow cast of the foliage plainly denoting this, and which, if not arrested in its early stages, soon brings about the tree's downfall.

On heavy and cold soils too much care cannot be taken in the preparation of the site for the trees, especially in affording ample drainage—that is, if not present naturally. The site—a northerly aspect, and which is the best generally that can be devoted to the culture of the Morello—is often, on account of its position, in anything but a satisfactory state both as regards soil and drainage. In this garden this Cherry succeeds splendidly, but at one time it would not do so, the branches dying away wholesale. The remedy was found in affording free drainage and devoting a good portion of the border solely to the roots, without any disturbance of the surface for other crops. The roots by this treatment are kept quite up to the surface; consequently they derive the full benefit of the sun's rays. In preparing the site the border was raised above the ordinary ground-level, a tile drain also being laid direct from the base of each station into the drain running along the

walk. Over the bottom, before returning the soil, flat tiles were laid, these in their turn being covered with old brick rubbish. To the soil, as it was being returned, was added a fair amount of burnt refuse and wood-ashes. As regards pruning, the trees are gone over in the early summer, shortening back any shoots not required for laying in so as to form spurs. In the early autumn, after all the fruit is gathered, the trees are generally overhauled, further pruned if necessary, and the shoots nailed in. My opinion is that the shoots are not best nailed in until the period named. In the first place it would interfere with the fruit, and, further, the shoots are enabled to become better ripened if allowed more freedom throughout the summer. Black aphid, often such a pest, will not be troublesome if the trees are syringed with an insecticide during the winter, and also before the buds burst in the spring. Black aphid can be kept under if carefully watched, but once let it get hold, the difficulty commences, and in the end most likely the trees will entirely fail. T.

The Strawberry-Raspberry.—I would like to know if any reader has grown the "Strawberry-Raspberry." I find it very poor, a dry, tasteless fruit.—LADY ALLISON.

[The so-called Strawberry-Raspberry is *Rubus palmatus*, syn. *R. sorbifolius*. Its only value is as an ornamental plant, both when in flower and fruit. Its fruit can hardly be considered edible. We have heard of the fruit being converted into jam, but are not in a position to give definite information on this point.]

Plum-trees too large.—What is the best thing to do with fruit-trees that are getting almost too large for one's garden?—C. W. H.

[The only thing to do under the circumstances is either to destroy the trees, which we imagine you do not wish to do, or to lift every other one and transplant elsewhere. This would provide more space for the remainder. If this plan is not feasible you could, if you have an orchard, and there is space available, transfer the trees thither or use them to form an orchard if you have land at liberty for doing so, planting the trees 15 feet apart each way if they are bushes or pyramids and 21 feet if standards. The trees could, of course, be reduced in size by cutting the branches back somewhat, but this would be a very drastic remedy and one we should not advise being adopted unless the circumstances were very exceptional.]

Raspberries unhealthy.—I enclose some Raspberry leaves, and will be glad to have an opinion on them. The crop has been bad for two years, and the leaves unhealthy. The fruit dries before ripening. The young growth is strong and vigorous. The plants have been in the same place for years. The ground has been heavily manured.—LADY ALLISON.

[The Raspberry leaves are affected with the Raspberry leaf fungus (*Phragmidium Rubi-Idæi*, for which remedies will not be of any avail this season. You should, however, be careful to burn the old fruiting canes, as also the foliage on the young or next year's fruiting canes when it falls later on. Next year spray the young leaves, as soon as they are fully expanded, with liver of sulphur (sulphide of potassium), using 1 oz. of the chemical to 4 gallons of warm water. The spray is more efficient if 4 ozs. of soft soap are first dissolved in a gallon of boiling water, then add the sulphide, and afterwards dilute sufficiently to make 4 gallons. The drying of the fruit before it ripens is due to another cause altogether, but unless we could see specimens cannot say with cer-

tainty the particular kind of insect, as injury of this description is due to insect agency. If you have any trusses of flowers and fruit not in too dry a condition still present on the canes we should be glad to see them and advise you further.]

Currant, Red Cherry.—Those who grow Currants generally ignore that fine variety known as La Versailles or Red Cherry, for the distinction, if any, is trifling. And yet this is not only a very prolific variety, but it also produces by far the longest bunches and most richly-coloured fruits of them all. The variety has somewhat brittle wood if allowed to grow loose, as Red Currants commonly are. Some bushes I saw lately are on clean stems well above the soil, and although some eight years planted are still comparatively small, as they have their shoots shortened back just as the fruit is ripening to enable them to

TREES AND SHRUBS.

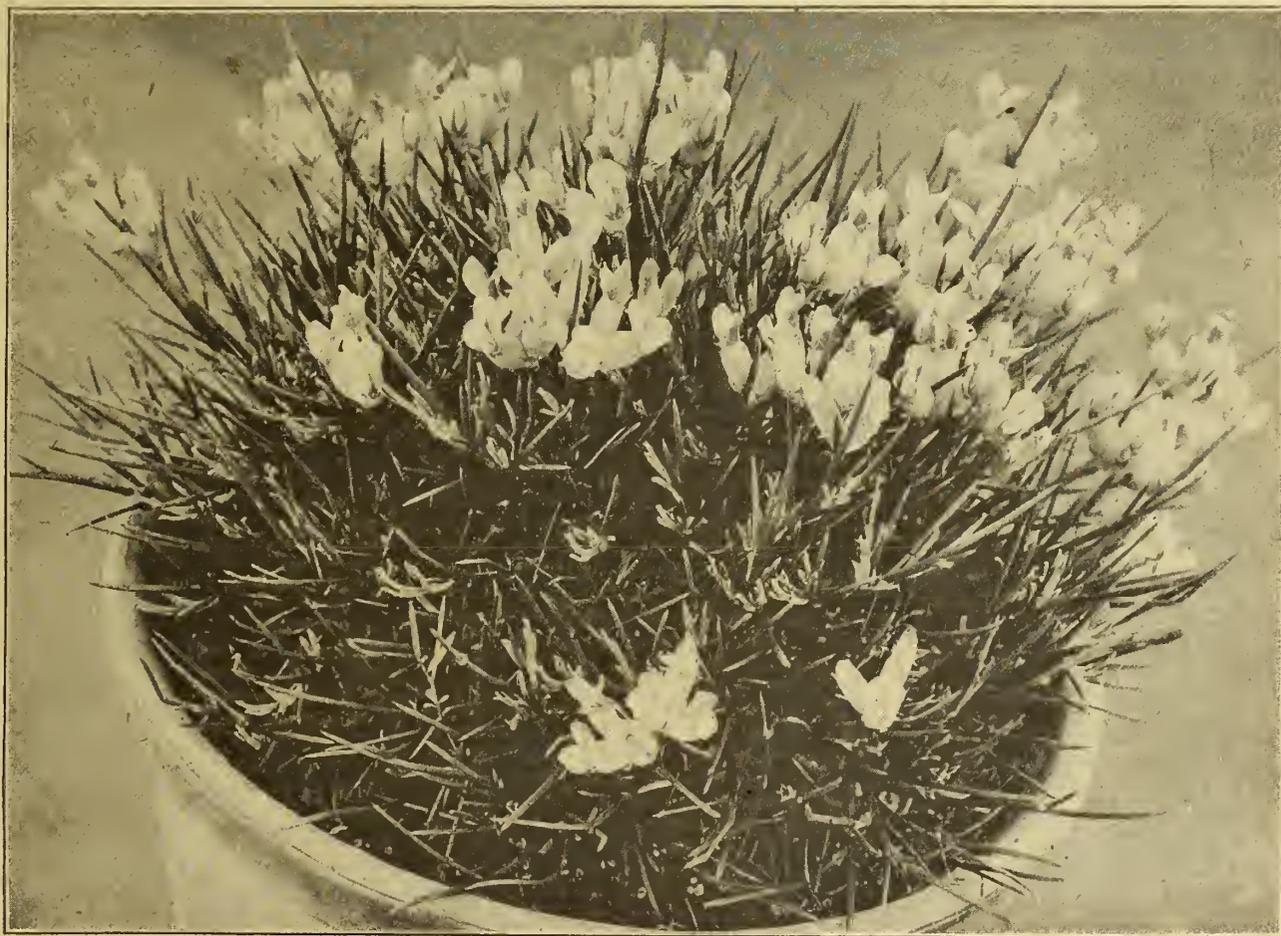

**THE HEDGEHOG BROOM
(ERINACEA PUNGENS).**

Thus, a native of Spain, whence it was introduced in 1759, is one of the most precious of miniature-growing rock shrubs, almost unique in habit, and quite so in the inimitable beauty of its Pea-shaped flowers, which are bluer than those of any other hardy leguminous shrub. Some doubt has ever existed as to its complete hardiness, and by reason of its rarity it is worthy of a place in the rock garden where natural protection is afforded. In southern England and at Cambridge, among other places, the plant is apparently hardy enough. The plant forms a dense, spiny, almost leafless bush—the few leaves that appear are small

or more across, the white petals being relieved by a central mass of golden stamens. *C. laurifolius* must be propagated by means of seeds, which ripen freely. These may be sown in sandy soil in spring, and as soon as the seedlings are large enough to handle they should be pricked off into boxes, eventually potting each plant singly, and keeping them in pots until they can be placed in permanent quarters, for it is almost impossible to transplant successfully plants which have been growing in the open ground for a year or two. When planting, there is rarely any need to introduce better soil or manure if the ground is poor, for the plant grows well in very inferior material.

MELIOSMA.

The nearest relations of the *Meliosma* among garden plants are the Sumachs

Erinacea pungens. Nymans.

be easily netted over, and in the winter are hard pruned, so that the heads are clusters of fruit-buds. The variety is a capital one for growing in trained or cordon fashion against walls to give late crops. Currants always set bloom-buds freely in such case, and when well trained and hard spurred carry heavy crops that are very easily netted up.—T.

Pyramid and bush fruit-trees.—Where from any cause these have to be kept restricted, the summer pruning should now be performed. With the exception of the leaders—i.e., the extension shoots on the branches and the main stems—all young growths should be stopped back to four buds on Apples, Pears, and sweet Cherries. Plums may be left a trifle longer. The Morello and Kentish Cherries may have the young shoots cut back to about half their length if the allotted space allowed each tree is filled. The leaders alluded to above should be either merely tipped or shortened back one-third, according to the exigencies of each individual case.—A. W.

and quite silvery—in which are set the pretty flower clusters. It flowers in May. In the rock garden a sunny spot should be selected and perfect drainage given. It is not very particular as to soil, very sandy loam or peat and loam suiting it quite well. It can be propagated by cuttings or layers, and occasionally by seed.

CISTUS LAURIFOLIUS.

THIS is the hardiest and the tallest-growing of the various *Cistus*s, and is excellent for a sunny position or for planting on a dry bank. *C. laurifolius* is a native of south-west Europe, and under normal conditions it grows from 5 feet to 6 feet in height. Its evergreen leaves are dark and ample, thus serving as an excellent groundwork for the large white blossoms which appear freely over a period of six weeks, from the middle or end of May. The fully-expanded flowers are each 3 inches

(*Rhus*). Three of them are considered to be hardy, namely, *M. cuneifolia*, *M. Oldhami*, and *M. Veitchiorum*, all Chinese.

M. CUNEIFOLIA was introduced by Messrs. J. Veitch and Sons, and flowered for the first time in their nursery at Coombe Wood in July, 1909. In a wild state it forms a large tree, but in this country so far it is only a well-branched shrub which flowers freely every summer. The leaves are not unlike those of the Japanese Loquat, having regularly pinnate nerves, marginal teeth, and a dark green glossy surface; but they are smaller, the largest being about 8 inches long and 4 inches wide. The flowers are white, and in effect they are like those of some of the Sumachs.

M. VEITCHIORUM has noble pinnate leaves each 2 feet or more long, with five pairs of leaflets and a terminal odd one, the largest being 6 inches long and 3 inches wide; the rachis and principal nerves dark

red, the other parts a rich green. It forms a fairly large tree, not unlike a Walnut, and the panicles of small white flowers are said to be 18 inches long and very decorative. The young shoots are stout with smooth bark, and the leaves when they first develop are dark crimson. Wilson found the trees in flower in June at an elevation of 5,000 feet to 7,500 feet in South Washan, Western China.

M. OLDHAM is another pinnate-leaved species, but it is more like an Ash than a Walnut, the leaflets being about 3 inches long with teeth on the margins, and the rachis dull red with a large boss, by which they are attached to the smooth light grey bark of the very stout young shoots; when young the leaves are of a rich chocolate-brown colour. The tree is said to be about 50 feet high, and the white flowers, borne in large terminal panicles, are said to be fragrant. All three species are represented by healthy examples in the Kew collection.—*The Field*.

THE BARBER IN THE GARDEN.

THE pictorial advertisements of nurserymen inviting orders for trees and shrubs distorted out of all recognition suggest that there is a danger of this decadent form of gardening gaining some hold on the public taste. This would be deplorable at a time when beautiful flowering shrubs from China and Japan are coming to this country and are found to be hardy in our climate. With so large a choice of trees, shrubs, and plants of rare beauty and grace ready to our hands there never was a time when there was less reason to revert to the efforts of the barber for the decoration of our garden.

There seems to be some confused idea in the minds of those who distort trees that this gives an old-world charm to a garden. This idea probably comes from the frequent coincidence of topiary work with old houses. Thus a sentimental affection for a bad thing has been created in the minds of many people because of its association with a good thing. So hardened in this false sentiment are the admirers of topiary work that to remove shaved trees from the neighbourhood of a picturesque building would almost certainly leave them lamenting that the old-world charm had gone, whilst to the eye of an artist it would have demonstrated that the old-world charm, unobstructed by misshapen objects of plant life, stood fully revealed.

A defender of the barber's work has rashly asserted that "the attempt to copy and reproduce Nature artificially seemed to result only in vulgar desecration." It would be difficult to imagine a defence more easy to dispose of than this. The barber's work is the most flagrant example of vulgar desecration that can be cited. For instance, a bird is a beautiful form of creation. The topiarian attempts to copy and reproduce its form artificially in a shrub, with the result that he ruins the shape of a shrub and burlesques the beauty of a bird.

To those who realise that no man's life is long enough to do more than stand on the threshold of a vast store of tree and plant life infinite in beauty and variety, and to touch but the fringe, this shaving of trees and shrubs seems but a pitiful and degrading thing.

Perhaps there are few things we are so apt to pride ourselves on as our good taste.

It is really no matter for pride at all. Good taste is a more likely comrade of humility, and goes with a childlike reverence for the work of the Creator, as shown to us in the clouds, the mountains, the waves, the forests, the flowers, and in the flight of birds.

PLANTS AND FLOWERS.

INDOOR PLANTS.

ZONAL PELARGONIUMS FOR WINTER.

THE Zonal Pelargonium is one of our most beautiful winter-flowering plants, but it is seldom we see it grown to perfection. We attribute this failure to (1) lack of proper pinching and training of plants when young; (2) an insufficiency of sun to ripen the growth during summer; and (3) too much moisture about the house during winter, causing the flowers and foliage to damp off. The

PROPAGATION of the Pelargonium is simple. In the early spring select young ripened tips, cut off the base of the cutting below the joint, trim off one or two of the bottom leaves, and insert the cuttings in 5-inch pots filled with sandy soil, three in a pot, and place them in a slight bottom-heat until they root. When well rooted turn them out of their pots and re-pot them singly into small pots, using a compost of light loam, leaf-soil, and sand. After potting, place them on a shelf near the glass, where they will soon start into growth, provided too much water is not given before they root, as it tends to make the soil sour. In a few weeks they will be ready for another shift, this time into 3-inch pots, using the same compost. Place them in a dry place, water carefully, and pinch out the tops so as to make them of good shape. The last shift should be into 6-inch and 7-inch pots, using a compost of good fibrous loam two-thirds, the rest being manure, bone-meal, or rotten cow-manure, well-decayed leaf-soil, and some sharp clean sand. Another point of much importance must not be lost sight of, and that is firm potting. If the soil is left loose the result will be a batch of leggy plants denuded of foliage at the base.

About the middle of June remove the plants to a cold-frame; some recommend placing them outside on a bed of ashes, but frame treatment will be found more satisfactory, as the lights can be put on to ward off heavy rains which sometimes occur. Zonal Pelargoniums will stand extreme drought better than frequent soakings. During this period occurs the most important phase in their history, and that is the first item which we have mentioned as the cause of failure—viz., lack of proper pinching and training of the plants when young. This must never be lost sight of. Pinch out the points of the shoots when they have made about two leaves, and keep at it. If one side does not attain the same height as the other, leave it unpinched, as nothing looks worse than an unshapely plant. In addition to the points of the shoots being pinched, the flower-buds must also be removed until the end of August, when all pinching must cease. The

WATERING must be carefully looked after. The plants may require water two and sometimes three times a day during hot weather, but it is better to err on the dry side. Every other day supply the plants with weak liquid-manure, or if this is not to be had then some artificial manure. Do not give too rich food or the growth will be very succulent, which destroys the chance of a good show of flowers in consequence of the growth being insufficiently ripened. While the plants are in the frames give plenty of air, and let them have the full force of the sun, gradually as the plants increase in size and the roots commence to ramify.

The best house for the growth of Pelargoniums is a light, airy one, facing south, if possible, so as to get the full advantage

of the sun at all times. Remove the plants inside about the middle or end of September, according to the weather. Give plenty of air, unless cold, and, above all, refrain from pouring water about the house (unless very hot), as it tends, as before stated, to cause the damping off of foliage and flowers at a time when least expected. In dull, damp weather a little fire-heat is essential, in order to keep the atmosphere in a normal condition. If it be desired to preserve the blooms for cutting, etc., a tiny drop of floral gum dropped into the eye of each flower will keep the petals from falling.

So much for plants from cuttings, but what to do with the old plants is a point which many cannot understand. Some do not believe in cutting the plants down to the base. They sometimes cut off a little from the tops, which leaves the old plants, if they do live, skeletons that have not a leaf or bud within 12 inches or 18 inches from the pot. Prune down those long-stemmed plants, care being taken to prune to an eye pointing outwards, which secures the plants from being too thick in the middle. Put the plant into a warm place, and if it gets over the double misfortune—i.e., the long stems and bleeding—it will do so sooner by being kept in a warm place. Give it no water until the wound is healed; after that give it a plentiful supply, and if a little water is sprinkled over the plant occasionally it will not fail to make a good plant if the roots are healthy. When the plants have started into growth shake the soil from among the roots, trim them, and re-pot in the compost previously advised. The cultural requirements are identical with those given the first year's plants.

NOTES AND REPLIES.

The Chili Jasmine (*Mandevilla suaveolens*).—Kindly advise as to how best to propagate *Mandevilla suaveolens*, of which I have three plants in full blossom covering a south-south-east wall. We have a mild climate, but would this stand any colder, frosty regions?—RIDUNA, Alderney.

[This is a well-known greenhouse climber that flowers during the latter half of the summer and early autumn. The blossoms are a good deal like those of a very large pure white *Convolvulus* and are very fragrant. It is a native of Buenos Ayres, and in the particularly favoured districts of England, such as in the Isle of Wight and in South Devon and Cornwall, it can be successfully grown as a wall plant out-of-doors. It climbs by twining, not by means of tendrils. The *Mandevilla* is particularly liable to red-spider, which quickly causes the leaves to drop. It succeeds much better planted out in a prepared border in the greenhouse than in pots. It needs a light, airy structure to flower it well. It can be increased from cuttings of the short, stubby side shoots placed in pots filled with sandy soil and plunged in a gentle bottom heat until rooted. See to it that the young plants do not get pot-bound before shifting them, as if this happens the growth is checked and more liable to insect pests.]

Begonia Corbeille de Feu.—This *Begonia* is not mentioned in the answer to "A. M. B." (page 468), who needs varieties with small flowers in abundance. This quality is certainly very pronounced in the variety *Corbeille de Feu*, and as "A. M. B." stipulates for varieties from about 1 foot high, the height attained by this may not militate against its use. It belongs to the fibrous-rooted section, having been raised by M. Lemoine, of Nancy, between *B. semperflorens* and *B. fuchsoides*. It forms a freely-branched specimen, from 18 inches to 1 yard in height, and will flower

throughout the summer; indeed, if grown in pots and employed for greenhouse decoration, it will continue to bloom till autumn is well advanced. The flowers are of a bright-red colour. Of late years this variety has been a great deal used in the flower garden. It cannot be raised from seeds, but cuttings strike root readily, so that it can be obtained at a comparatively cheap rate.—K. R. W.

HIBBERTIAS.

ACCORDING to the "Dictionary of Gardening" there are about seventy species of Hibbertia known to botanists, practically all of which are natives of Australia. There are, however, very few in cultivation in this country; in fact, only three species are generally met with.

The most desirable species and the ones referred to are:—

HIBBERTIA DENTATA, a free-growing

during the summer. They give off a most unpleasant smell. Both will grow and flower profusely planted out in a good-sized greenhouse or conservatory. A third species is, however, quite a different plant. This is

HIBBERTIA READI, sometimes met with as *H. Reidi*. It forms a compact, twiggy bush, clothed with small leaves, while the yellow flowers, borne during the summer, are each about the size of a shilling. Good flowering examples of this species may be grown in pots 5 inches in diameter.

All of the Hibbertias can be readily struck from cuttings of the half-ripened shoots put into sandy soil in a propagating-case where there is a gentle bottom-heat. They will all thrive in ordinary potting compost.

Perpetual-flowering Carnations.—The flower-buds on the earliest plants grown for flowering in winter are now getting into a

CHRYSANTHEMUMS.

OVER-FEEDING CHRYSANTHEMUMS.

A FREQUENT cause of failure in Chrysanthemum culture is over-feeding. The desire to obtain plants of gigantic proportions in the matter of leaves and stems is so widespread that in very many cases feeding is overdone. Frequently all will go well with the plants up to the time of their final potting, then a too free use of highly concentrated manures in the soil causes the check. The roots refuse to run freely in the good things prepared for them, and the successful beginning is thereby spoiled. But more often the breakdown occurs in regard to over-fed plants at the time the blossoms are opening, pithy, soft growth being unable to build up flowers of good substance. There is very little produce of the garden, be it flower, fruit, or vegetable, brought to perfection when the conditions are such that a sappy form of growth is secured. Who expects Grapes to perfect well when the leaves remind one of Rhubarb, Tomatoes to finish a good crop with stems as thick as an ordinary broom-handle, or Roses to bloom well on stems as large as one's finger? And so with the Chrysanthemum. Give the plants a long season of growth, a compost that will allow of free rooting, ample pot-room, and steady feeding when the soil has become exhausted, then a good flowering season is sure to follow. Of course, attention to moisture at the roots and plenty of space in the open quarters must never be neglected.

Anything that is done in the way of feeding should be to aid the formation of surface roots. These tiny feelers keep the plants in perfect health if kept going up to the last. Some growers have great faith in top-dressing, and it is no doubt beneficial. Only one must afterwards be particularly careful in the matter of watering, or the soil at the bottom of the pot may become dry, whilst that newly placed on the surface is quite moist. Loam of a fibrous nature and bone-meal make a perfect top-dressing. We do not like the mode sometimes seen, of putting on the surface a thickness of animal manure, such as that of horse or cow; nor is such strong burning material as fowl-manure safe, unless mixed in a small proportion with the loam. Soot, again, if used too freely, would burn what roots there are on the surface of the soil, instead of assisting their increase. Fertilisers have great effect in showery weather; it is then surface roots run most freely, and again after the plants are placed under glass. Meanwhile, when the weather is brighter, and the calls for root moisture are great, we may use manures in a liquid form. These are various and well known. The rule which cannot be too often mentioned regarding their use is that they be applied very weak and often rather than in strong doses occasionally. It is important, in feeding Chrysanthemums, that we should note those of more weakly growth and feed them less.

Although these notes refer principally to the culture of the Chrysanthemum for large blooms, good cultivation is desirable all the same for whatever purpose the plants are intended. They all need what is known as feeding to maintain a healthy vigour just now when the abundant leafage and swelling flower-buds are causing such a strain on the sap-giving powers of the roots. The value of careful feeding will be seen in the blooms.

Flowering shoot of Hibbertia volubilis. From a photograph at Nymans.

climber of a woody nature. The slender, thong-like shoots are of a twining character and quickly mount upwards by means of any support available. They, as well as the young leaves, are bright red in colour. When mature the foliage becomes of a bronzy-olive tint, which serves admirably as a setting to the bright yellow flowers. These, which are about a couple of inches across, are borne during the first three months of the year, when greenhouse climbers in flower are by no means numerous. While glass protection is necessary in most parts of the country, it will succeed as a wall plant in the extreme south-west, where so many otherwise tender subjects thrive. A second species, herewith illustrated, is

HIBBERTIA VOLUBILIS, which is as vigorous a climber as the preceding, but of a stouter nature. The leaves are narrower than those of *H. dentata*, and green. The flowers of *H. volubilis*, too, are larger than those of the other, and borne, as a rule,

forward condition, and the plants must be housed. If allowed to remain outside after they commence to show colour, the blooms are never so fine as when developed under glass. The inside of the house is thoroughly washed before introducing the plants. The plants are arranged thinly on the stages, and the house fumigated at the first opportunity to get rid of any fly. Tying and disbudding must be attended to, this latter operation being essential if the finest blooms are desired. If after housing, any hot weather is experienced, the blinds will be let down for an hour or two in the day and the plants lightly sprayed late in the afternoon. This will have a similar effect to the night dews to which the plants are accustomed when out-of-doors.

Schizanthus.—Plants intended for flowering early in spring have been potted into 4-inch pots and stood in an unheated frame close to the glass. The pots should be quite clean and well drained, and for potting use a light, rich soil with plenty of well-decayed leaf-soil incorporated with it. The plants should be kept in a cool frame throughout the winter, the *Schizanthus* being very impatient of heat.

VEGETABLES.

TOMATOES.

WHERE there is yet a good deal of unripe fruit on indoor plants the foliage may be further reduced to let in sunlight and air, while the plants should be prevented from extending further by pinching the point-growth back to the last truss of fruit, *i.e.*, when the house is shortly required for other purposes. To further expedite matters the fruits, as soon as they commence to colour, if gathered, will allow of the remainder ripening more quickly. Tomatoes finish colouring in a short time if laid out on shelves or stages in full sun. Plants now coming into full bearing should have all side growths persistently removed and the leaders kept tied to the stakes or trellis, as the case may be. Plants intended for winter and early spring fruiting should now be shifted into 12-inch or 14-inch pots, leaving ample space when doing so for top-dressings to be applied later on. Fruiting plants now in pots require ample supplies of water fortified with stimulants, frequently renewing the surface mulch, or until the plants show signs of exhaustion, when they should be dispensed with. The weather of late has not been altogether favourable for outdoor Tomatoes, especially when the plants have not the advantage of the shelter of fruit-walls or low supporting walls of green-houses, etc. In any case the fruit must now be fully exposed to the sun, to which end the foliage must be considerably reduced, the best way of accomplishing this being to cut half of each leaf away. As it is useless to allow further trusses of flowers to develop and set, the plants should be kept stopped. G. P. K.

NOTES AND REPLIES.

Growing vegetables under glass near smoky town.—Will you kindly give me some advice about growing vegetables under glass near a smoky town? I have good glass-houses (modern), and should like to grow Potatoes, Peas, Lettuces, and French Beans, if you could advise me whether it is worth while, and, if so, how to proceed. I think the heat of house is important. We have very little sun in winter, though the houses get all there is.—E. G. BRIGHE.

[With such climatic conditions as those you have to contend with we do not feel justified in advising you to attempt the cultivation of the vegetables you mention under glass. They can, of course, be grown in glasshouses, and successfully, too, but a clearer atmosphere than yours and all the sunshine obtainable are very essential. These conditions, combined with the necessary knowledge in regard to management, can alone command success. Fire-heat, of which, except in the case of French Beans, but little indeed is required, would not, we should point out, prove of any avail in providing compensation for any deficiency of light and solar influences. If, after perusing the above, you still feel inclined to venture the growing of vegetables in your houses, we advise you to confine your attention to Potatoes and Lettuces, for which you will require beds of soil some 18 inches deep in the first case and 12 inches in the second on either side of the footpath if the houses are span-roofed, or one side only if they are lean-to. If you do so decide, please write us again, when we will give you further instructions.]

Celery ridges may be usefully employed for many catch crops. It is a common practice to utilise the ridges for Lettuces and Radishes, but other quickly maturing crops may also find room on them. Early Cauliflowers and Spinach may be mentioned, and at present a very fine crop of White Stone Turnip is

following on the same ridge upon which the first Lettuces were grown. A dwarf French Bean, such as Canadian Wonder may be sown upon the ridges of the trenches devoted to late Celery, and with the depth of soil an excellent crop may be expected.—KIRK.

Broad Beans.—The tips have been pinched out of the final sowing of Broad Beans. Occasionally, if a line from which the crop has been picked be cut back, well watered, and top-dressed, a second growth will follow, which may give a welcome basketful or two at the close of the season where Broad Beans are in request. Even should the crop not ripen, the labour is, in the case of failure, trifling.

Tomatoes.—Reduce the foliage on Tomato plants in the open air, and give a dressing of artificial manure to hasten the development of the fruits before cold weather sets in. These plants are easily injured by cold, wet weather, and protection should be given if possible. If planted against a wall or fence, a few old lights can easily be placed over them, these also assisting the ripening of the fruits.

GARDEN FOOD.

SOME VEGETABLE MARROW RECIPES.

THE Vegetable Marrow is nice when plain boiled and served with butter, salt, and pepper, or with a good white sauce poured over, but the Marrow is capable of being made the *piece de resistance* of the mid-day meal, especially during the summer, when food should be simple.

VEGETABLE MARROW EN CASSEROLE is nice for supper, as it can be prepared in the morning, and the casserole will cook it without any trouble during the day. Take a medium-sized Marrow, peel it and cut a piece off the top. Set this last carefully aside until the Marrow is stuffed. Scoop out the seeds, but leave the outside part entire. Take a cupful of cold boiled macaroni or Rice, the same quantity of fine breadcrumbs, a tablespoonful of chopped Onion, a teaspoonful of chopped Sweet Herbs, and sufficient white sauce to make the whole moist. Add a little cayenne pepper and salt to taste, and mix thoroughly. Fill the Marrow with the mixture and replace the top, fastening it in place with two small skewers. Butter the inside of a casserole and lay the Marrow in it, pour over a cupful of nice vegetable stock, add a small piece of Lemon, a faggot of Sweet Herbs, a small Onion, and salt and pepper to taste. Stand the casserole in a moderately warm oven or on top of the stove, and cook gently for three hours. Take up the Marrow, keep hot, and thicken the sauce in which it was cooked with a dessertspoonful of flour rolled in butter. Cook for five minutes, pour over the Marrow and serve at once.

MARROW PIE is made with very small Marrows. Take a deep pie-dish and butter thickly. Spread half an inch of breadcrumbs over the bottom, and sprinkle with a tablespoonful of white sauce. Cut the Marrow into cubes and lay on top of the crumbs, then a sprinkling of chopped Onion and a layer of sliced Tomato. Continue the layers of Marrow, crumbs, Onion, and Tomato until the pie-dish is full. The last layer should be of crumbs. Take a small cupful of good vegetable stock, sufficiently salted, and pour down the side of the dish. Sprinkle a little dissolved butter on the top, and bake in a moderate oven for three-quarters of an hour. Cover the dish for the first fifteen minutes with a plate, then remove the plate and let the top brown.

MARROW FRIED.—Another useful recipe consists of slices of Marrow dipped in flour, flavoured with salt and pepper, and then fried a rich brown in deep fat. Place the slices on croûtes of fried bread, and fill the centres with the following mixture. Take a cupful of cold boiled macaroni, and chop finely. Put into a pan with a tablespoonful of Tomato sauce, and the same of thick cream; salt and pepper to taste. Heat the mixture, and, after filling the centre of the Marrow, cover the whole with grated Parmesan cheese. Put the whole in the oven or under a gas-griller to brown the tops slightly. Sauté some halves

of Tomatoes, place one on top of each slice of Marrow, sprinkle a tiny pinch of chopped Parsley in the centre, and serve at once. A simple variety of this dish is to fry the Marrow slices and Tomato halves, and lay the latter on top of the Marrow, and send to table very hot. This makes a nice breakfast dish. H. T. C.

OLIVE OIL V. COD LIVER OIL.

THE fat that is usually added to malt extracts is cod liver oil, which also possesses real food value. The truth is that cod liver oil is, strictly speaking, a food and not a medicine, and its food value is very much the same as that of any other oil. But there are distinct disadvantages against cod liver oil, and very few patients find it palatable or pleasant to take. Cod liver oil often causes nausea or vomiting, and may even cause diarrhoea. A leading medical authority writes that it "must not be given if detrimental to the appetite." Of course, it is possible in a large degree to disguise the fishy smell and vile taste of an oil which is prepared from the livers of the cod fish. Why not use olive oil, an oil which scarcely possesses any odour and that not unpleasant, and a taste that is decidedly agreeable to the majority of people? It is a bland oil and a food of the highest nutritional value, being readily digested and assimilated by the majority of patients. There seems to be no doubt but that olive oil combined with extract of malt makes in every way as wholesome, nourishing, and valuable a preparation as the old-fashioned combination of cod liver oil and malt, and has the additional advantage of palatability.

THE DIGESTIVE PROPERTIES.—The combination of olive oil with extract of malt does not destroy the diastasic ferments present in the latter. Therefore the preparation is equally valuable as an aid to digestion of starchy food. This is a matter of the greatest importance in dealing with the diet of invalids, and especially those that require the administration of not only the malt, but also the oil.—DR. OLSEN in *Good Health*.

NOTES AND REPLIES.

Salads.—I want to make a speciality of salads, and am hoping to hear of some little book which will tell me of the proper ingredients, and of the herbs, etc., which should be grown. Can you help me?—H. W. MAJENDIE.

[No doubt a book could be written about salads, as of many other things; but it is quite needless. Good cooks anywhere require but a good Lettuce and Olive oil. Very often they put in no other herb, but if another is used it is a little Chervil or chopped Chives. Most gardens have these things now. In the old days, when Lettuce was not much or well grown, people sought many other things, but they are now useless in view of good garden Lettuce. The *salade de legumes* much used in France is quite another thing—is, in fact, a dish of mixed cold vegetables.—ED.]

A substitute for Spinach.—Boiled Radish leaves make a very good substitute for Spinach. The leaves should be carefully washed and be boiled until tender in a good quantity of salted water. Pour into a colander and press out all the water with a saucer. Chop the leaves finely and return to a clean saucepan with a small piece of butter and serve piled on squares of buttered toast. Quite a quantity of Radish leaves can be cut from even a small bed. The roots are delicious boiled in salted water and served up either with plain dissolved butter poured over them or else with a little white sauce, after the method employed for young Turnips. The roots must be young and tender or the flavour will be coarse and unpleasant.—H. T. C.

OUTDOOR PLANTS.

GENTIANA PRZEWALSKII.

THE accompanying illustration shows well one of the most beautiful of the summer-flowering Gentians, the more valuable because preceding *G. semptemfida* and some others that are with it in time of flowering. A native of China and a vigorous plant withal, it produces a rosette of long, flat, strap-shaped leaves, very suggestive of the Himalayan *G. decumbens*, from which issue numerous decumbent stems bearing at their extremities clusters of large sky-blue flowers which render the species highly ornamental in its day. The habit of the plant and its free-flowering are so well shown in the figure that further remarks thereon would be superfluous. As among the most desirable, however, the attention of rock gardeners should be directed to it in the hope that by raising it freely from seeds effects of a more sumptuous nature, as opposed to the usual

mains in force. This temporary stoppage is rather a blow to a flourishing and steadily expanding business, but the department concerned (the Board of Trade) has personally assured us that it really is only for the period of the war, and made absolutely necessary by the shortage of shipping; and we sincerely trust that by this time next year matters may be entirely different, the shipping commandeered by the Government released, and the prohibition removed, when business will be resumed on its old footing, and we shall, of course, continue to post each catalogue directly it is printed, exactly as in the past.—R. SILBERRAD & SON.

PÆONY-FLOWERED, DECORATIVE, AND COLLARETTE DAHLIAS.

THE Dahlia, apart from its value for exhibition, has made wonderful strides in popularity during the last few years. Formerly the big, globular show and fancy

embracing the three types of Dahlia just enumerated. One of Mr. Jarrett's objects is to create a love for this flower by asking less fortunate growers in the more congested areas of the Metropolis to visit his garden in the flowering season. The

COLLARETTES were first inspected. Here was to be seen a fine lot of promising seedlings. Good things that Mr. Jarrett has raised are Rainbow, aptly described because of its varied colours, and a good type of the collarette. Biscuit is a beautiful biscuit-coloured sort, and a self. A promising seedling is Alfred Dennis, the colour deep chestnut-maroon, with a good collar. Of the popular up-to-date sorts, the more promising were Holyrood (ruby, tipped gold, with a yellow collar), Carron (bright scarlet, tipped gold, with a yellow collar), Eden (a pure white self), Abbe Hugonnard (purple, margined white, collar white), Henri Farman (yellow, blotched red, with a cream collar), Tuskar (rosy-crimson, tipped white), Grand Papa

Gentiana Przewalskii at Hillbrook Place.

isolated examples, might result. Fresh seeds usually vegetate freely, the seedlings if well grown flowering the third year. How long subsequently the species will continue to give a good account of itself is a question of cultivation. In a good depth of loam, leaf soil, sand, and a little manure the plant does well, remembering always that root disturbance is not appreciated and that seedling-raising constitutes by far the best method of increase.

E. H. JENKINS.

Bulbs from Holland.—The total prohibition placed by the Government on the importation of all bulbs, plants, etc., "for the period of the war" renders it utterly impossible for the usual supplies to be sent across from Holland and elsewhere this season, consequently the bulb catalogue of G. C. Van Tubergen (Haarlem, Holland) is not being printed or distributed. We are extremely sorry, but must, of course, abide loyally by the Government regulation so long as it re-

kinds predominated. Their popularity waned somewhat, however, with the advent of the Cactus Dahlia, which, because of the attractive manner in which the flowers were set up at the leading shows, induced flower-lovers to take up their culture. So many of the Cactus Dahlias, at least the earlier introductions, were of little value in the garden, as the flowers of most varieties were hidden away under the foliage. It is only recently that Cactus Dahlias better suited for garden embellishment have come into prominence, and a welcome will be given to the newer introductions, in which the flowers stand up well above the foliage.

Quite recently I visited the garden of Mr. J. A. Jarrett at Anerley, near to the Crystal Palace, who has devoted himself almost exclusively to the cultivation of the collarette, decorative, and Pæony-flowered types of the Dahlia. Here are to be seen at the present time not far short of a thousand plants blooming freely, and

Charmet (bright crimson, cream collar), Star of Montplaisir (old rose, collar pale rose, edged white), Countess Ivy Hardegg (maroon, tipped white, collar white), Gold Tip (scarlet-crimson, tipped gold, collar golden-yellow), and Scarlet Queen (scarlet with a beautiful golden collar). The better

PÆONY-FLOWERED KINDS were Geisha (scarlet and yellow), Aphrodite (a chaste white self), Eleanor (rose-pink), Mrs. J. C. Vaughan (a yellow self), Sheila (a lovely pale pink), John Green (a yellow and scarlet flower), Balak (rosy-crimson), Holman Hunt (dark crimson), Lord Milner (yellow, suffused crimson), Amber Queen (a lovely amber-coloured flower), Dormouse (a remarkable deep crimson sort), and Bayard (a bronzy-red flower). The

DECORATIVE SECTION represents blooms of diverse form and colour, the flowers varying from those of medium size to those of enormous proportions. Some of

these are very striking and the following were noteworthy. Reginald Cory (a variety with a dwarf, bushy habit, and blossoms of brilliant crimson, tipped white, very free flowering), Delice (rose-pink), Kaiserin A. Victoria (a white self), Mrs. J. Lang (bright red self), Papa Charmet (deep crimson self), Queen Mary (rose-pink), St. George (salmon-scarlet, tipped white), Amphion (pink, suffused heliotrope), Princess Juliana (creamy-white), Leviathan (terra-cotta, shaded bronzy-purple), Madonna (a pure white self, very large), Jeanne Charmet (white, edged pink), Warneford (a white self), and Alice Roosevelt (a beautiful rose-pink sort).

The foregoing are a few of the more attractive sorts out of a very large collection, and may be taken to represent the better sorts of the respective types. Mr. Jarrett thinks well of the new Star Dahlias, and of these he has Crawley Star (pink), White Star (white), and Yellow Star (one of the newest and best of this new type). I must confess to a distinct prejudice against the Dahlia in the past, but the display made by this enthusiastic amateur convinced me that the more modern introductions possessed a beauty and charm hitherto unrecognised by me. The dwarf, single-flowered sorts, used as an edging to a long, serpentine path, with plants of the Peony-flowered and Decorative sorts in borders rising gently on either side, created a picture which I shall not soon forget.

D. B. C.

DAFFODILS IN THE TURF.

For the spring garden the varied forms of Narcissi are invaluable, not alone for planting in the borders, but for naturalising in the Grass, the latter method, now so largely followed, not only creating a most pleasing effect, but also being, in many cases, better suited to the requirements of some varieties than culture in tilled ground. As an instance of this, two kinds may be specially cited—namely, the Tenby Daffodil (*Narcissus obvallaris*) and *N. pallidus præcox*, both of which succeed better in the Grass than in worked ground. Several of the smaller and less vigorous varieties are well adapted for the rock garden, such as the tiny *N. minimus*, the varied forms of the Hoop-petticoat Daffodil (*N. Corbularia*), golden, sulphur, and white, the variety of *N. triandrus* known as Angel's Tears, and *N. t. pulchellus*, though the last, being of stronger constitution, succeeds equally well in the border, as well as the quaintly-formed *N. cyclamineus*, which delights in a moist root-run. Many of the golden and bicolor varieties of the trumpet Daffodil are suited for naturalising in the Grass, such as the deep yellow Golden Spur, *N. maximus*, *N. Emperor*, and Queen of Spain, an attractive variety, bearing clear yellow flowers of peculiarly distinct form, the trumpets lacking the flanged rim possessed by all other varieties of this section. Of bicolors, *N. Horsfieldi*, *N. Empress*, and *N. Grandee* form a fine trio, and when planted in quantity have a striking effect. They are very similar in size and colour, and attaining perfection in the order in which they are named extend their display over a considerable period. The old double Daffodil also succeeds well in the Grass, though it lacks the grace of form of the single varieties. Sir Watkin is the most vigorous of the incomparabilis section, and is well fitted for naturalisation, while many of the numerous varieties of the same class, though of less robust growth, make themselves equally at home. The Star Daffodils (*N. Leedsi*) are particu-

larly graceful and delicate, with their narrow cream-white petals and slender, swaying stems, and never reveal their attractions so fully as when growing on a grassy slope, while the Poet's Narcissus, or Pheasant's-eye, when planted in thousands, creates one of the loveliest spring pictures imaginable.

VIOLETS.

In naturally cold soils I have found Violets do well on a bank at an angle of about 45 degs. and facing due south. The plants did not make very large leaves and the flowers were not large, but they were freely borne. All runners should be removed as they form, and thus avoid weakening the main crowns. This is very important, as Violets grow rapidly from the middle of August to the early part of October, and any undue crowding would have a bad effect, especially on plants that are to be lifted and forced, or grown in cold-frames. Some growers lift their plants early in September, but I know one very successful grower who does not lift till the end of the month or early in October because he is reluctant to disturb the plants while they are growing so freely. He continues to lift plants for frames till Christmas. I have never found it of much advantage to make up hot-beds in frames, old Cucumber and Melon beds being quite as good, or better. Level the surface of such and add more good compost so as to secure, at least, a bed of soil 1 foot deep. Old hot-beds do not sink, so that it will not be difficult to secure a surface 1 foot or so from the glass. Before lifting the plants thoroughly soak the soil, then a good quantity will adhere to the roots. The double-flowered varieties may be planted 7 inches apart each way, but such of the singles as Princess of Wales and La France need as much space again. Close the lights only when there is frost, fog, or very wet weather, otherwise ventilate freely. BOURNE VALE.

AMONG THE HARDY FLOWERS.

Is it more profitable to buy large than small bulbs when the latter are considerably cheaper? The small bulb is not so likely to please the eye, and the amateur will generally buy the large, solid bulb. It does not always follow that the big one is the better of the two, and I should like such experts as Mr. Jenkins to favour us with his experience and views. I know some men of long experience who invariably buy the smaller bulbs unless they want them for a special purpose to make a good display the first year, irrespective of their conduct afterwards. If we want a full display the first season, and do not mind about subsequent seasons, it will probably be better to buy big bulbs. On the contrary, I have learned that the big bulbs of different genera sometimes exhaust themselves the first year by flowering or by making offsets, and do not bloom so well for a season or two afterwards. I have in my mind's eye a lot of small bulbs purchased for the garden of a public institution. They were English grown, were bought as small bulbs, were very cheap, and were derided by people who had been in the habit of buying the biggest bulbs they could get. They bloomed wonderfully well the first season, and much better the next one. In the second season they made a better display than the large bulbs bought and planted at the same time. Daffodils, Snowdrops, Crocuses, Scillas, and Glories-of-the-Snow were included in this purchase.

TIGER LILIES.—The lateness of the Tiger Lilies is a great recommendation. We are told that in many gardens, especially

those in which there is much lime, the bulbs gradually dwindle away after reaching maturity. We see this Lily in all kinds of gardens, so that we can hardly realise the possibility of its failure. It is so cheap, too, that it may readily be tried by everyone. Whether the variety *splendens* or that known as *Fortunei* is the better of the two is a disputed point, but I like *Fortunei* better than *splendens*. The double variety is one of the few double Lilies worth growing, though I can hardly say that it is as pretty as the others. I plant these Lilies about 9 inches deep when in light soil, or about 6 inches in heavier ground.

NEW ENGLAND MICHAELMAS DAISIES.—The New England varieties, derived from *Aster Novæ Angliæ*, although on the tall side, are fine things for the back of a border and are capital for cutting—as, indeed, is all the family. I see the height of the tallest varieties stated in catalogues as 5 feet, but these are often taller, and I have seen them 6 feet or more when in good soil. For small gardens the dwarfier ones are better in most instances. Several of the new shades of colour are also lovely. I like *Ryecroft Purple* (good purple), *Ryecroft Pink* (soft rose-pink), *Feltham Blue* (fine bright blue), and *Lil Fardell* (rosy-pink). These are all about 1 foot less in height than the older varieties, and one called *Mrs. Mitchell* is said to be 18 inches less than the old *A. Novæ Angliæ* and its varieties *rosea* and *rubra*.

AN AMATEUR OF HARDY FLOWERS.

POLYANTHUSES: AUTUMN NOTES.

With the cooler nights both these and coloured Primroses will make more growth, especially in the case of seedlings. Where these were sown last autumn, in the open, or in warmth in the early part of the year, and have been given good culture, they are now large plants. Few things pay for liberal treatment more than these. Where so many fail is in starving them in boxes in their early stages, and relying on divided plants, which are often in poor health. When plants are in this state the best thing is to destroy them. True they give some flowers of a poor colour, and cannot be compared to young, vigorous seedlings.

If the best results are to be obtained from Polyanthuses the soil should be in good heart. Few things pay better for a liberal use of manure at planting time where the soil is light and poor. Good rotten dung should be worked deeply into the soil before they are planted. No hard and fast line can be laid down as to the time of planting. They may be lifted with large balls when coming into bloom and replanted. From a garden point of view no time is so good as from the middle of October till the end of the year. Spring planting can be recommended where the soil is of a heavy nature and early planting cannot be done. Light soil should be made firm before planting, and in such, a mulch in spring is helpful. Another important point in planting is to keep the plants low down in the soil.

Those left in the seed-bed, if carefully lifted and planted in their permanent places in October, will bloom well in spring. J. CROOK.

ERIGERON PHILADELPHICUS.—This is a fine plant for the border, ranging in height from 1 foot to 2 feet. The flowers are pink and purple, and useful for cutting. If the plants are prevented from ripening seed the flowering period is prolonged often as much as two months. *Erigerons* succeed in any good, rich garden soil, and should be given a sunny position.—E. T. ELLIS, *Wetwood, Ecclesall Sheffield*.

LAVATERA OLBIA.

It is very likely the handsomer plants of the Mallow tribe are not quite enough used in gardens. They are very showy and very easily grown, and often very good in colour. This I put in my Heath garden, where it looked uncommonly well just at a time when the Heaths began to be less attractive.

W.

NOTES AND REPLIES.

Eyebright (*Euphrasia officinalis*).—I am curious to know if anyone has found this medicinal herb have the same effect as *Primula obconica* has on some people. I collect herbs for a newly-started herb-collecting and growing association in my

it could be the Eyebright. The doctor came again on the fourth day, when it was beginning to get better, and said it undoubtedly was Eyebright that had caused it. Even now, on the fifth day, there is a good deal of irritation, though the extreme redness and swelling have disappeared.—BOSMERE.

Watering in the open air.—When watering is necessary it should be really well done, that is, sufficient should be given to moisten the soil to the full depth to which it was dug or trenched. One such watering in the driest weather is sufficient to serve a whole week, and will keep the plants in luxuriant growth; but daily surface dribbles have a contrary effect, for, naturally enough, the roots of the plants

also looks very neat, but under bright sunshine soon shrinks up and requires renewing. Well-rotted stable manure, broken up very fine, or also sifted, is another good material—too good in a certain sense for some kinds of plants; and, therefore, its use should be limited to those kinds only that delight in rich food, amongst which are all the sub-tropicals, Dahlias, Violas, Verbenas, and Calceolarias. It would be better that all plants requiring a liberal amount of manure should be given it directly in the soil when the beds are being prepared by digging or trenching.

ROYAL HORTICULTURAL SOCIETY.

SEPTEMBER 12TH, 1916.

THE exhibition held on this date was one of the most attractive and extensive for some time past. With the ordinary fortnightly meeting was associated the annual exhibition of the National Dahlia Society. The Dahlia, indeed, was holding high festival, albeit we inclined to the view that certain types—the Pæony-flowered among them—were somewhat rougher than usual. It is, however, a garden rather than an exhibition flower, and, as such, not to be judged at close quarters. The singles and Pompons were distinctly good, the latter, though models of formality, attracting many. The stands of "Show" and "Fancy" sorts appeared to fascinate nobody. Coming sections, doubtless, are the "Star" and "Collarette," and these, with the finer "Decorative" and "Pæony-flowered" sorts, did not lack admirers. The exhibition Cactus varieties shown on boards attracted much less than those on stands, and the fact should not be lost sight of by the society in question. Some eighteen varieties were granted Awards of Merit. Apart from these there were beautiful displays of fruit, Carnations, Orchids, hardy flowers, shrubs, alpines, and Ferns.

HARDY FLOWERS.

In all probability the choicest thing in this department was the brilliant golden-orange-flowered *Oxalis lobata* shown by Mr. Clarence Elliott. Only an inch or two high and flowering naturally now and through October, it is one of the choicest things a rock garden could contain at the present time. It requires sun and warmth, the shilling-large flowers in sharp contrast to the almost olive-green of its leaves. *Senecio pulcher* stood out from all else in a group shown by Mr. W. Wells, junr. It is not a novelty, rather in the nature of a rarity or one whose peculiarities are insufficiently understood. Its uncommon colouring—purplish-magenta—when other composites, chiefly yellow-flowered, are plentiful in the garden, makes its presence as welcome as it is distinct. Hence the great sheaf of it was effective. *Verbesina Purpusi* is a new yellow-flowered composite from Mexico we hope to refer to again. The new Italian Aster, King George, and a great array of Delphiniums as fine as these are in summer were other things in the same group. In a somewhat comprehensive gathering of the best Tufted Pansies from Messrs. Carter Page and Co. none stood out so conspicuous as the blue-flowered W. H. Woodgate, which, if not new, is highly meritorious. As companions *Kittie Bell* (mauve), *Crimson Bedder*, and *Peace* (white) are desirable. Indispensables like *Archie Grant* and *Maggie Mott* were also on view. In a collection of alpines and shrubs arranged by Mr. G. Reuthe there were many things of importance and a few novelties. Quite in the front rank of the latter was *Rhododendron primulinum*, best described, per-

Group, of *Lavatera Olbia* at Gravetye.

neighbourhood in Suffolk, and was told I could find this herb in a large disused chalk-pit. I had never seen the plant before, and certainly never picked it, but there it was in quantity, and I picked a large basket of it and took it straight to the oast-house used for drying the herbs. From the moment of picking it my face began to burn in an unaccountable way, but I concluded it was the sun, it being a hot day. The next day my face was scarlet with an irritating rash. That day I went to another chalk-pit and picked more, and next morning was so bad I sent for my doctor. He thought it was the sun, but the irritation was maddening, and on the third morning my face was much swollen. I had begun to wonder if

will go in search of moisture, and if this is superficial, the roots are formed on the surface only. A thorough watering, when the plants are first put out, to settle the soil to the roots is all that is necessary till new roots are established. Then, if the weather continues dry, a soaking once a week is all that is needed to keep the plants in perfect condition. The heavy waterings here advised render it necessary to stir the soil with a small hoe or pointed stick a day or two after watering, but this would be rarely required were mulching more general. If applied as soon as the plants are put out in May, mulching saves a lot of labour. Cocoa-fibre refuse is the neatest. The next best material is decayed vegetable or leaf-soil. This, sifted,

haps, as a soft yellow counterpart—though larger of flower—of *R. intricatum*. It is a new addition from China, and a lovely plant withal. Far more imposing was the handsome lot of *Eucryphia cordifolia*, with remarkable bunches of white, brown-anthered, cupped flowers at the summit of leafy stems. The flowers, too, emit a subtle fragrance of May blossom. *Clethra arborea* afforded large terminal clusters of pendent white flowers, the pinky buds and calyces adding to the good effect. The flowers emit a spicy fragrance. Among hardy Heaths two novelties, *Erica cinerea atrorubens* and *E. c. rosea*, were conspicuous for colour alone, though but few flowers remained. *E. vulgaris* fl.-pl. is a plant of great charm, too, but not new. The rarely seen *Stobæa purpurea* was also noted, and the lovely new *Gentiana calycosa* among many things. *Berberidopsis corallina* was brilliant, and, near by, a mass in bloom of *Cyclamen hederæfolium* was most effective.

ROSES.

A collection was shown by the Rev. J. H. Pemberton, who has for some time been devoting attention to the raising of new perpetual-flowering cluster sorts. *Callisto*, a novelty of the moment, soft yellow with apricot-coloured buds, is charming. *Clytemnestra*, with a more pinky effect than usual, was very beautiful. Moonlight (semi-double white), Queen Alexandra (cupped pink and white single), and Daybreak (yellow buds and creamy flowers) were some in a beautiful lot.

CARNATIONS.

Only one collection was displayed, that coming from Messrs. Allwood Brothers. Undoubtedly the gem of the lot was Bishton Wonder, a pink-flowered variety of exceptional colour and size, surpassing the old Clove in rich perfume. We know nothing like it in the perpetual-flowering set. It is quite new; its fragrance will make it popular. White May Day is also a novelty with all the good attributes of the original, while Wivelsfield White, the most prolific white, and Salmon Enchantress still hold their own.

FERNS.

Some good things in these came from Messrs. H. B. May and Sons, *Nephrolepis* being in strong force. Of first importance was *N. Whitmaniana* compacta, *N. gracillima* and *N. Marshalli* compacta being others of note. All are more or less of densely plumose character, if differing in outline and details, and are among the most serviceable of this large race. *Davallia Mooreana*, *Cheilanthes elegans*, and *Asplenium marginatum* are distinct. In shrubby *Veronieas*, of which also a collection was staged, *La Perle* (of reddish-carmine tone) and *Lavinia* (royal purple) were the more conspicuous.

ORCHIDS.

Cattleya Venus variety *Victrix*, shown by Mr. Pantia Ralli, Ashted Park, and *C. V. Golden Queen* by Messrs. Charlesworth, each gained an Award of Merit. Both have yellow sepals and petals, and richly-coloured lip. Other choice things from Messrs. Charlesworth included the "Flower of the Gods" (*Disa grandiflora*), the golden-flowered *Lælio-Cattleya Thyone*, and *Cattleya Gaskelliana* alba. His Grace the Duke of Marlborough sent *Cattleyas* and *Lælio-Cattleyas* in variety, *C. Woodon-aurea* being choice and good. The finest thing in a group from Messrs. J. and A. MacBean was the pure white *Dendrobium Sanderæ*. One plant had pseudo-bulbs each nearly 4 feet long

and carried about sixty flowers. A cultural commendation was given. *D. Dearei*, also pure white, was very fine. The most charming and distinct novelty shown by Messrs. Armstrong and Brown was *Brasso-Cattleya Mme. Hye*. The *Brasso-Cattleyas* have usually large flowers, the huge lip widely expanded and heavily fringed. In the plants under review a small, compact flower is seen, all the parts being modified, the delicate shades of mauve rendering it all but unique. *Cattleya Snowdon* is a chaste and lovely white, and so, too, *C. Clæsiana alba*. Among the finer examples from Messrs. Sauder and Sons, *Cattleya Magali Sander* (pure white) stood out prominently. *C. Aeis*, *C. Lord Rothschild*, *C. R. Prowe* (very pure and beautiful), and *Lælio-Cattleya Henry Greenwood*, whose long, narrow sepals and brilliant crimson-purple lip and snow-white throat gave it an air of distinction, were also noted.

DAHLIAS.

Exigencies of space preclude our referring to the exhibition of Dahlias in detail. Generally, however, the competition was not keen, that creating wide-spread interest being the Cory Challenge Cup class for a group of decorative garden Dahlias on a table space 25 feet by 3 feet. Three imposing collections were staged, the challenge cup (value seventy-five guineas) being awarded to Messrs. Carter Page and Co. for a particularly good lot, representative of several sections of the flower. The pure white *Aphrodite* and the pink-flowered *Delice* were very conspicuous. Surpassing these, both in interest and imposing display, was the Gold Medal group from Mr. Reginald Cory, Duffryn, Cardiff, the donor of the cup. The group occupied a table across the whole of the western end of the hall and consisted entirely of varieties raised by the exhibitor, who takes the keenest interest in all that pertains to the flower. Needless to say, many good things were shown, the whole constituting a great attraction.

FRUIT.

There were two novelties shown in this section, and both are full of promise. *Tomato Best of All* (new strain) is one of them. Exceptional firmness of flesh, uniform and rich colour of the fruits, larger clusters and shorter-jointed habit of growth are among the good points claimed for the new-comer. The habit is of considerable importance, as the variety will be much better suited to pot cultivation. A fine lot of solid fruits was shown by Messrs. Sutton and Sons. The other fruit novelty was *Daniel's September Black Currant*, which gained an Award of Merit. Of this, gathered fruits in bunches and fruiting sprays were shown, all from the open. Needless to say, a September-fruiting *Black Currant* should be in great demand. The fruits shown were about the size of those of *Lee's Prolific*. Mr. J. A. Nix, Tilgate, Crawley (gardener, Mr. E. Neal), showed a superb lot of fruit, the *Grapes* very fine. *Muscat of Alexandria*, *Muscat Hamburg*, *Gros Maroc*, and *Appley Towers* were among those staged. *Peaches* and *Nectarines* were first-rate, as also a large tray of fruits of *Pear Durondeau*. A collection of several dozen varieties of *Apples*, together with *Damsons*, *Bullaces*, and *Crabs*, came from Messrs. Spooner and Sons. *Jacob's Seedling* was particularly well coloured, as also was *Worcester Pearmain*. *Wealthy*, *Stirling Castle*, *Pott's Seedling*, and *Norfolk Beauty* were others of note.

A complete list of the plants certificated and medals for groups will be found in our advertisement columns.

THE WEEK'S WORK.

OPEN-AIR GARDENING.

IN BLOOM SEPTEMBER 13TH.—*Ceanothus* (in variety), *Buddleias*, *Magnolia grandiflora*, *Rhus* (in variety), *Hardy Fuchsias* (in variety), *Clerodendron trichotomum*, *Hydrangea paniculata grandiflora*, *Veronicas* (in great variety), *Aloysia citriodora*, *Daphne Cneorum*, *Spartium junceum*, *Viburnum Tinus*, *Catalpa bignonioides*, *Clethras* (in variety), *Clematis* (many species and varieties), *Cistus* (in variety), *Helianthemums* (in variety), *Vaccinium Vitis-idaea*, *Oxalis floribunda*, *Omphalodes cappadocica*, *Mertensias*, *Linarias*, *Sedums*, *Androsacos* (in variety), *Dryas octopetala*, *Silenes*, *Gentiana asclepiadæa*, *Potentillas* (in variety), *Convolvulus mauritanicus*, *C. althoides*, *Nierembergia ricularis*, *Mesembryanthemums*, *Gypsophilas*, *Verbena venosa*, *Platystemon californicus*, *Pratia angulata*, *Scabiosa Parnassi*, *Plumbago Larpenzæ*, *Tufted Pansies* (in variety), *Antirrhinums* (in variety), *Pentstemons* (in great variety), *Calceolaria amplexicaulis*, *Cannas*, *Cosmos*, *Marguerites*, *Pelargoniums* (in variety), *Begonias*, *Verbenas*, *Petunias*, *Clarkias*, *Nemesias*, *Salpiglossis*, *Nigella*, *Lavateras*, *Hollyhocks*, *Salvias*, *Summer-flowering Chrysanthemums*, *Collinsias*, *Sweet Sultan*, *Scabious* (in variety), *Carnations* (in variety), *Herbaceous Phlox* (in variety), *Delphiniums*, *Montbretias* (in variety), *Liliums* (in variety), *Hyacinthus candicans*, *Gladiolus* (in variety), *Echinops*, *Bocconia cordata*, *Eryngiums*, *Helianthus*, *Erigerons*, *Achilleas*, *Sidalceas*, *Cimicifuga racemosa*, *Campanulas* (in variety), *Romneya Coulteri*, *Asters* (*Michaelmas Daisies*) (in great variety), *Tritomas* (in variety), *Dahlias* (in variety), *Acanthus Candelabrum*, *Chrysanthemum maximum* (in variety), *Agapanthus umbellatus*, *Thalictrums*, *Morina longifolia*, *Bergamot*, *Yuccas*, *Cyclamen hederæfolium*, *Colchicum autumnale*, *Ericas* (in variety), *Menziesias*, *Static* (in variety), *Astilbes* (in variety), *Lysimachia clethroides*, *Lythrum roseum*, *Epilobiums*, *Lobelia cardinalis*, *Pampas Grass*, *Nuphar*, *Water Lilies*, *Single Arrowhead*.

WORK OF THE WEEK.—Many varieties of Hybrid Tea Roses are again flowering freely. The ground about the plants is stirred as frequently as possible, not only to destroy weeds, but in order that the ground may become properly aerated. Rambling and climbing Roses, having practically finished flowering for the season, a general, almost final, pruning is being carried out, cutting out old wood with a free hand, relying on basal shoots solely where the wall or whatever the plants are trained to does not exceed in height what one may reasonably expect the young growths to cover in one season. Where walls, pillars, and pergolas are high a few two and three year old shoots are retained, cutting them back at irregular levels to a strong bud, thus encouraging the production of strong-flowering growths part of the way up, and which will eventually reach the summit. These, together with shoots from the base, will clothe the whole from bottom to top. I would emphasise the importance of pruning at the present time, for it not only relieves one from having to do it in the spring, but greatly assists in the ripening of the current year's growth by allowing free play for sunshine, light, and air, and thus to a certain extent ensuring plenty of bloom. A quantity of Darwin Tulips was planted during the week. Home-grown bulbs are first cleaned and sorted, rubbing off imperfect outer scales; these are planted rather closely together and about 4 inches deep. Cuttings of Pinks inserted in the summer are now well rooted, and will be transplanted to their flowering quarters forthwith. Pinks succeed best in a medium or light soil, and no rank manure should come into contact with the roots. The season has suited the hardy Fuchsias, and they are now a mass of bloom. Greater use might be made of these, as they grow well in almost any soil, and under all sorts of conditions. The plants may be increased by division, by root cuttings, and by cuttings.

F. W. GALLOP.

Lilford Hall, Oundle.

SOUTHERN COUNTIES.

Late Muscats.—In wet weather fire-heat is absolutely necessary, not only to maintain a suitable temperature but to allow for the admission of a certain amount of fresh air, or sufficient of it to prevent stagnation of the internal atmosphere and moisture condensing on the berries. As the berries are now colouring fast the observance of the foregoing simple, though important matters should have strict attention. Keeping the vinery clear of plants and covering open tanks for the time being, as well as watering the border when necessary on fine mornings, when full ventilation can be afforded, will also assist in simplifying matters in this direction. If the border is covered to a depth of 4 inches with dry litter it will serve to arrest moisture arising therefrom and prevent the atmosphere becoming charged with an undue degree of humidity. If the border is an outside one, or partly so, it should be covered with something of a waterproof nature to prevent its becoming saturated, as this is inimical to the long keeping of Muscats after they are ripe. Where the disease known as "spot" is troublesome the bunches should be scanned daily, cutting out all affected berries as soon as detected and burning them. This, if it does not act as a preventive, tends to keep contiguous berries from becoming affected.

Other late Grapes.—No effort should be spared in forwarding the ripening of late-keeping varieties of Grapes, such as Lady Downe's, Gros Colman, Mrs. Pince, Lady Hutt, etc., during the present month, particularly when the roots are in an outside border. In some localities such a border will, after the recent heavy rains, be quite moist enough for some time to come, and will therefore be best covered with something to shed off water and so avoid risk of the same becoming soddened. With an inside border the roots are more under control, and the colouring is not so liable to be arrested, as often occurs when the border is outside and the soil saturated by heavy autumnal rains. Fire-heat, as in the case of white Muscats, is very necessary, certainly at night if not by day, its employment in the last-named instance being governed, of course, by external weather conditions. Unless colouring is general stimulants may still be used when the border requires water.

General work in vineries.—The shortening hack to about half their length of laterals on Vines now clear of fruit, if not already done, should have immediate attention. Sub-laterals, if the premier leaves are still intact and in a healthy condition, should also be dispensed with. Where there has been an outbreak either of red-spider, mildew, or thrips, steps should be taken to effectually deal with such pests now that more drastic remedies can be employed. Another pest, and the worst of all to contend with, is "mealy-bug." This, too, can be dealt with in a more effectual manner after the Grapes are cut. Syringing with paraffin emulsion, and fuming the house two or three evenings in succession, are the means of killing off great numbers of the insects. Searching for and touching the insects with methylated spirit wherever they are found to be numerous or congregated together are, if tiresome, a very sure method of getting rid of them. Even if the Vines are clean a good syringing or hosing now and again is very beneficial. The adding to of borders in which Vines have been planted within the last two seasons can now be undertaken. In making these additions it is essential that the new portion be carefully connected with the old, which is best done by breaking down the face of the latter while the new portion is being built up.

Spring Cabbage.—The young plants raised from seed sown towards the latter end of August should, before they get too far advanced or drawn, be planted out. From the time of seed-sowing to the present, conditions have been favourable for free growth being made. Under existing circumstances planting out should be effected under advantageous conditions also, as the soil is thoroughly moist and warm. The plants should therefore get away quickly and become established before cold weather sets in. Varieties which form small hearts and turn in early, like Harbinger, may be planted from 1 foot to 15 inches apart each way. Larger-growing kinds need a

distance of 18 inches each way. If ground is not available for planting it is better to prick out the plants in rows 6 inches apart, with the rows standing 9 inches asunder, than for them to remain in the drills and become leggy. They can then be lifted with balls and planted later on when a plot has been got ready for them. In a general way spring Cabbage succeeds Strawberries, Onions, or Potatoes, but under existing conditions the work of preparation cannot always be undertaken when it should be. When planting does take place see that the surface is made firm and broken down to a fairly fine filth. In the case of pricked-out plants, planting should be done with a trowel.

Onions.—If by any chance there should not be a sufficiency of plants for setting out next spring, seed of such varieties as Lemon Rocca and White Leviathan may still be sown, doing so on a warm border. Exhibition varieties, such as Cranston's Excelsior and others, may also be raised outdoors now. This will obviate the necessity for doing so under glass next February. A. W.

MIDLAND COUNTIES.

Melons.—The latest batch has set a good crop of fruit. During sunny weather advantage is taken of the sun's heat to help the growth as much as possible by closing the house early in the afternoon with plenty of atmospheric moisture. Care must be exercised in the use of the syringe now that the days are shortening, and while having plenty of moisture in the house to counteract the effect of fire-heat, the foliage should be allowed to become dry before night. The roots require to be kept in a moist, but not sodden, condition.

Tomatoes.—Plants for fruiting in autumn and winter, and which were potted into 9-inch pots last month, have, at the base of the plants, set a quantity of fruit, which is swelling freely. Manure-water is afforded the plants once a week and the house ventilated by day and night. The plants are trained on the single-stem system, all lateral shoots being removed as soon as they appear. As soon as the top of the plant reaches its limit of space growth is stopped by pinching out the point. As the days will soon be short and dull it will be necessary to artificially fertilise the flowers or they will not set freely. A sharp tap on the trellis occasionally is usually sufficient to effect fertilisation, doing this when the sun is shining and the ventilators are open.

Begonia Gloire de Lorraine.—A batch of the more forward plants will now be allowed to bloom. As the flowers develop, overhead syringing is discontinued, but damping between the pots is done daily, as a dry atmosphere tends to encourage most pests. The house is ventilated freely on all favourable occasions, and when the plants are in full bloom a crack of air is left on all night to cause the air to circulate. The later-raised plants are kept growing freely, pinching out all bloom for the present in order that the plants may form a useful succession to the earlier batch. Very little shading will be required after this date. The house is closed early in the afternoon in order that the plants may get the benefit of the sun-heat.

Violets in frames.—These will now be transferred to their flowering quarters in order that they may become established before the winter sets in. Before lifting them see that they are thoroughly moist at the roots. The frames should face the south and be sheltered from east and north winds. The frames are partially filled with stable litter and leaves, treading the litter firmly or the plants will sink after they have been planted a few weeks. A layer of soil 8 inches to 9 inches deep is placed on the manure and leaves, and when the plants are in position they are just clear of the glass. A suitable compost consists of three parts good loam, one part leaf-soil, one part decayed manure, and a little silver sand. Allow ample room between the plants, and make them firm, keeping the crowns just above the level of the soil. For a time no water will be needed at the roots, but the foliage is sprayed on dry afternoons. The lights will be left off the frames for a few weeks if the weather is favourable.

Vegetables generally are very plentiful this year and of first-rate quality. Every precaution should be taken to guard the crops against early frosts, which may occur at any time now. Therefore, it is imperative to make the necessary provision for affording protection. French Beans which are bearing well should be protected in order that the crop, which might otherwise be lost in a single night, may be preserved for some considerable time to come. Cold frames containing Beans should now be kept closed, except in the hottest part of the day, when sufficient air should be admitted to keep the Beans from damping. Vegetable Marrows should also be protected.

Lettuces raised from seed sown in August are ready for transplanting into cold pits. The soil in these pits should be raised to within 15 inches of the glass and made moderately firm before the plants are put in. Where cold frames are available there need be little difficulty in maintaining a supply of salads throughout the greater part of the winter. Damping is most to be feared in Lettuces in pits during the winter, therefore sufficient space must be allowed between the plants. The lights should be left off the frames as long as the weather is favourable, but if wet weather occurs they should be replaced, allowing ventilation both at the top and bottom of the pit.

Endive should be planted in cold pits and treated in the same manner as recommended for Lettuce. The Batavian Endive is best for winter use, as it is not so readily affected by damp as the more tender sorts.

Herbs.—Where a constant supply of green herbs is required throughout the winter preparation must now be made to secure them. The best way is to set a pit, or part of one, aside for the purpose where fire-heat can be applied in cold weather. Mint, having been cut down a month ago in preparation for forcing, may now be lifted with a fork and the soil shaken from the roots. The plants should then be laid close together on a bed of leaves, over which has previously been placed a layer of leaf-soil, and covered to the depth of 2 inches with fine leaf-soil and well moistened with clear water applied at a temperature of 70 degs. to settle the soil amongst the roots. With a moderate bottom-heat young shoots will soon make their appearance, when abundance of air must be given to keep them from becoming drawn. Tarragon may be grown in the same pit. The plants should be cut over and placed in position without delay. This herb forces very easily, and a continuous supply can be easily maintained by placing a few clumps in moderate heat from time to time. Chives may be treated in the same way. If the plants have been cut over and placed on a gentle hotbed they will soon make fresh growth and continue to do so for some time. Further batches of roots may be placed in the bed as required throughout the winter. Marjoram may occupy one end of the same pit, but must be grown in pots and plenty of room given. Sweet Basil, the most tender of herbs, requires rather more heat, and should be grown in pots placed on a shelf near the glass in an atmospheric temperature of 65 degs. The last sowing of Chervil has been made under a south wall. This will keep its colour better during the winter than early-sown plants. F. W. G.

SCOTLAND.

Hardy-flower borders.—Anything which is noticeably shabby is slightly cut back, merely removing the flower-heads. A run through with the hoe disposes of seedling weeds, and does away with the necessity for hand-weeding when the dead stems are cut over in winter. The final display made by hardy plants is, in its way, the best of the year. Already the Kniphofias are on the point of blooming, large pieces of K. Uvaria carrying numerous spikes which are very telling. Daily additions are being made to the numbers of Asters in bloom, the latest noticed being A. Amellus bessarabicus, one of the best and most free-flowering, as well as one of the most attractive of the dwarf varieties. A border devoted prin-

cipally to blue flowers has been very good, and in spring seeds of *Nigella* Miss Jekyll were broadcasted through the intervals between the stools of the hardy plants. The season of the latter, with the exception of *Asters*, being practically over, the situation has been saved by the *Nigella*, which is now in full bloom, and which will endure until frost intervenes. *Pyrethrum uliginosum* (the Moon Daisy) is evidently earlier than usual, but this is not regretted, as in some years blooms are ruined by wet or cut over by frost. If any removals or alterations are proposed now is the time to take notes. It is a difficult matter to do this work satisfactorily when the plants have passed out of bloom.

Autumn-sown annuals.—Owing to the scarcity of certain kinds of bulbs, there will, no doubt, in many cases be a larger sowing than usual of hardy annuals in the course of the month. While annuals will do very well on even poor soil, yet, if an extra good display be wished for in spring, let the quarters be given a moderate dressing of well-rotted stable-manure and dug over. After allowing the ground to settle, and previous to sowing the seeds, it must be made firm by treading, rolling, or beating. To expect seedlings to survive a severe winter in loose soil is vain. A firm root-run makes the plants thrifty and short-jointed, and such plants may be relied upon to give a good account of themselves in spring. Seeds may be sown moderately thickly at this time, and when germination is fairly well advanced some thinning may be done. It is unwise, I think, to thin too severely in autumn. There are so many dangers of casualties among the seedlings during winter from frost, slugs, and vermin that the ultimate thinning may well be deferred until early spring. Properly treated, few things make such an excellent display as hardy annuals from September sowings, and while everyone has his particular favourites, yet a few which are especially valuable for this purpose may be named. These include *Saponaria calabrica*, *Silene pendula*, *Collinsia bicolor*, *Convolvulus minor* (especially the blue variety), *Lavatera trimestris*, *Candytuft* (white and pink), *Malope*, *Godetias*, *Clarkias*, and *Eschscholtzia californica*. *Mignonette*, unfortunately, cannot in every garden be relied upon from autumn sowings, and the same remark applies to *Poppies*.

Spring Onions raised in heat, having now completed their growth, have had their necks bent over to hasten the ripening. Without being in any way exceptional, the crop is a bulky one, the bulbs firm and hard, and likely to keep well. As there is yet growth in the case of sown-out Onions, they will be permitted to stand yet awhile.

Leeks.—The Leek quarter was cleaned and well hoed during the week, and afterwards some chemical manure was scattered along the lines and more soil drawn to the necks of the plants.

Celery.—A trench of red Celery which had become rather weedy was cleaned, the side growths removed from the plants, and a slight moulding up given. At the same time exhausted Lettuces and Turnips which were grown on the ridges of this particular trench were removed to the rot-heap.

Chervil.—This herb is not in great request during the winter, but to meet possible requirements a small sowing has been made in a warm and sheltered place, the position selected being close to a walk, so that the plants may be readily protected should severe weather follow.

Peas and Broad Beans are kept regularly picked. The yield of both has surpassed expectations, and the season will yet be prolonged for a time. French Beans, although later than usual in coming into use, are now bearing freely, the climbing varieties especially so.

Cabbages for spring cutting.—Seedlings from a recent sowing having now attained a suitable size, these have been pricked off into nursery beds. Plants from this sowing are generally of superior quality, and bolting is practically unknown. W. McCUFFOG.

Balmie Gardens, Kirkcudbright.

CORRESPONDENCE.

Questions.—*Queries and answers are inserted in GARDENING free of charge if correspondents follow these rules: All communications should be clearly written on one side of the paper only, and addressed to the EDITOR of GARDENING, 63, Lincoln's Inn Fields, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent each should be on a separate piece of paper, the name and address being added to each. As GARDENING has to be sent to press some days in advance of date, queries cannot always be replied to in the issue immediately following their receipt. We do not reply to queries by post.*

Naming plants.—*All who wish their plants to be rightly named should send fair examples of each—the stem, leaf, flower, or fruit. (Snippets of leaves and points of shoots are useless.) Not more than four plants should be sent in any one week by the same correspondent. Where more than one kind is sent they should be numbered. Of conifers the fruit should always be sent.*

Naming fruit.—*Several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruits for naming, these in many cases being unripe and otherwise poor. We can undertake to name only four varieties at a time.*

PLANTS AND FLOWERS.

Four good exhibition Roses (A Boy).—It is very difficult to confine oneself to such a small number, as there are so many good ones, the growth of which varies so throughout the country. The following are four good ones: A. K. Williams, Mrs. John Laing, Lady Ash-town, and Dean Hole.

Primulas unhealthy (Bournea).—The leaves of your Primulas have been attacked by red-spider and thrips caused by keeping the atmosphere and surroundings too hot and dry. The Chinese Primula dislikes a hot, dry atmosphere, and as soon as the plants are established in their flowering pots the best place for them is a cold frame, allowing them plenty of room, air, and light, with a slight shade during the hottest part of the day. An occasional syringing is very beneficial, this in the case of your plants being imperative so as to get rid of the thrips and red-spider. When the nights get cold they should be taken indoors, standing them on flower-pots and giving them a light position, keeping the surroundings cool by admitting fresh air when the weather outside warrants this.

FRUIT.

Pears cracked (Boyfield).—The cracked condition of the Pears you send is due to a fungus known as *Fusicladium prinum*. The remedy is to spray the tree with a wash containing sulphate of iron in addition to caustic soda, such as that designated Woburn wash. Do this as soon as the tree has been pruned and the soil beneath it cleared of rubbish. Then, before the buds burst, when the tree has flowered and the fruit has set, and again in from two to three weeks afterwards, spray with Woburn-Bordeaux mixture. Use both insecticides according to the directions sent with them.

VEGETABLES.

Indian Corn (A Boy).—If we could rely upon a very warm season, there would be but little difficulty in growing this. If given a little care at the start it can be had quite good even in our variable climate. In a favourable season it may be sown in the open, but better results are had by raising in a frame and planting out late in May. The best results are secured by sowing under glass in small pots, thinning to the strongest, and planting out in May in well-manured land, in shallow trenches. The Maize has to make its growth in a short season, hence the necessity of ample food and a liberal root-run. Few plants require more water at the roots in hot, dry weather. This can be given in the shape of liquid-manure, or, failing this, a

good plan is to mulch the plants liberally with rotten manure between the rows, watering freely when dry. Given an open, sunny position, growth will be rapid once the plants get a start.

SHORT REPLIES.

Thos. Burnett.—The reason of the failure of your plant to bloom is that the pot is too small for such a plant as you refer to. It ought to have a pot at the very least 8 inches in diameter. Had you given it some liquid-manure to assist the roots, which in the very small pot you mention are practically starved, we have no doubt that it would have flowered. —**D. G.**—The bulbs of Ailsa Craig Onion, if grown on deeply-trenched and well-manured ground, have, from a January sowing and end-of-April planting, been recorded as weighing over 3 lb. each. Any seedsman could supply seed of this variety of Onion. —**A. Raby.**—There is nothing wrong with the piece of Cactus you send. The rusty-looking appearance is, we think, due to the exposure in the open air. —**G. F. A.**—There is no need to use the two, one or the other only being necessary. Basic slag is suitable for all crops, except when grown on soils rich in lime. —**H. M. W.**—Your best plan will be to write to a seedsman and tell him the character of your soil, when he will send you the most suitable mixture.

NAMES OF PLANTS AND FRUITS.

Names of plants.—**E. C.**—*Bocconia cordata.* —**Link.**—Clematis bloom very much knocked about, but seems to be *Nellie Moser.* —**E. Clarke.**—It is a wholly different species, the blue one being *Echinops Ritro.*

Names of fruits.—**C. W. H.**—Plums: 1, Denbigh or Cox's Emperor; 2, Is, we think, a small fruit of Belgian Purple.

CATALOGUES RECEIVED.

BARR AND SONS, King-street, Covent Garden.—*Gold Medal Daffodils, 1916; List of Hyacinths, Tulips, Gladioli, Irises, etc.*

DOBIE AND CO., Edinburgh.—*List of Hyacinths, Tulips, Sweet Peas, Carnations, etc.*

W. DRUMMOND AND SONS, LTD., 57 and 58, Dawson-street, Dublin.—*List of Bulbs, 1916.*

F. GIFFORD, Montague Nursery, Hornchurch, Essex.—*Special List of Newer Delphiniums, Phloxes, etc.*

JAMES CARTER & Co., Raynes Park, London, S.W.—*List of Bulbs, 1916.*

Parcels sent to our office insufficiently stamped will, in future, be refused.

Bulb growers will oblige by sending early copies of their Lists and Catalogues to MANAGER, "Gardening Illustrated," 63, Lincoln's Inn Fields, London, W.C.

Guaranteed British Bulbs.

Free carriage and packing will be given to all orders of 10s. value when cash is sent with order. Smaller orders should have 6d. extra enclosed.

Daffodils.
Emperor, deep yellow, 9d. doz., 5s. 6d. 100.

BAD FLOWER GARDENING AT KEW.

I WENT to Kew early in September to see what the summer had left of the beauty of the flower garden, and saw a dismal sight. The large beds alongside the central walk showed some of the poorest and most ineffective plants in cultivation. Lantanas, dwarf, poorly-coloured Fuchsias, Ageratum without any sign of stem or leaf, Catmint of no beauty, and Pyrethrums. Far better have no beds along this central walk if so poorly filled as these, with plants of no grace or distinction. If there were a real flower garden in Kew there would be no need for flower beds here, and the kidney-shaped beds of shrubs might be enlarged and improved by the addition of the many noble plants that thrive best with shrubs.

Coming to the flower garden in between the Palm-house and pond the effect was wretched indeed, both in plants and general effect.

ERRORS AS TO PLANTS.—The aim seems to be the exclusion of every graceful or beautiful plant that does not conform to one mean standard—dwarfness. The whole thing is a survival of the worst time in flower gardening, the attempt to imitate a bad carpet of Victorian days, now abandoned by all with eyes for a real garden. Everything of the least distinction is ruled out, Delphiniums, long-blooming Roses, the Cardinal flowers of Eastern America, lovely tree Poppies of California, Clematis, Honeysuckle, and Jasmine. To attempt to make a flower garden by excluding all the most beautiful hardy flowers is an absurdity, and the failure complete.

ERRORS AS TO CLIMATE.—In our often cold summers the choice of a few South African plants to the exclusion of the really hardy and beautiful plants of the northern world is a disastrous mistake. The white Pelargoniums of the present flower garden at Kew are miserable, draggled things, no effect and no beauty close at hand. The first consideration in making a flower garden in our land would be the plants that enjoy the cool rains and storms, as many of the best plants do—not covering before the gales, as the tender plants do. Though the soil of Kew is warm and open, the very opposite of much of that north of London and in Sussex, it does not make much difference, the effect is wretched in cold summers.

WHAT TO DO FOR A REAL FLOWER GARDEN.—The whole of the space between the

Palm-house and the pond should be laid out as a real garden, with beds as simple as in a cottage garden. The present streaky beds are quite useless for growing or showing plants. There should be no Grass. Gravel or stone walks and stone edgings should be the rule. There is plenty of Grass in the place without using it in the flower garden. From the Palm-house towards the pond there should be a real pergola, giving shade in hot days. The pergola is one of the best things in the gardens of southern Europe, and even better for us because we can grow a greater variety of plants on it. It should be formed not by a gardener or a botanist, but by an architect, and built to last. There is no good example of a pergola at Kew. Throughout the country there are many wretched things made of wire and rustic sticks which begin to rot as soon as up. It would be a distinct gain to show a well-formed and well-covered pergola in the flower garden here.

A GREAT OMISSION.—The grace and beauty of water and waterside plants which might well be brought into the foreground are wanting almost wholly here. The best addition to our hardy plants ever made was the coloured hardy Water Lilies. The finest water one could desire for these is at Kew, in front of the flower garden. It is abandoned to the ducks, when it might be adorned with groups of every hardy water Lily. The ducks might well go to the Thames or to some other pool in the woods. This is a Royal botanic garden and not a place for waterfowl, which are the worst things one could have near plants. Kingfishers and other birds cross over my ponds without injuring the flowers, which, if left to the ducks, would vanish. It is most important on an island country to show all the beauty of the water and waterside plants that can reasonably be seen in a flower garden.

There is no example at Kew of a good mixed border with plants well chosen and artistically arranged, and such a border would help much as an example, but now almost every garden in the land is disfigured by ill-made mixed borders. The whole garden should be based not on the exclusion of every pretty plant as it is now, but it should show all the beautiful plants that flower in summer and early autumn.

CLIMBERS EXCLUDED.—To make a flower garden without climbers is absurd. All the noble climbers of the northern world

should be seen in this garden. The sombre Ivy forming a line all round the Palm-house should be replaced by the most beautiful of the evergreen and summer-leaving climbers of the north. Ivy being in every wood and on nearly every house is out of place here. In this way we might show the beauty of all climbing plants of the north. Dividing and shelter lines, too, rightly made in the flower garden itself, should show all the climbers that may grace a garden in our clime. W. R.

[No reflection is made in this article on the director or gardener. It is the system, stereotyped for long years, which is attacked. What we want is a director with courage to put a stop to this travesty of flower-gardening. Now, when there are fine examples of true flower-gardening, it is more than ever to be desired that the change should be effected.—Ed.]

NOTES OF THE WEEK.

Little Othello Dahlia.—A singularly bright plant and very effective. It is rather dwarfer in habit than most Dahlias, and worthy of extended use in the flower garden.

Delphinium grandiflorum and its varieties.—I have been much struck with the beauty of these of late. One, a very light and charming blue, pleased me much. A rich fine blue, it formed a most attractive bed at Kew in early September.—W.

Philesia buxifolia.—On June 1st nine flowers opened on one plant of Philesia buxifolia, and at the end of July there were seven more flowers on the same plant. I have grown the Philesia for at least sixteen years, and never before had a second lot of flowers. In 1912 I had more than twenty flowers in June.—E. CHARLES BUXTON, *Coed-Derw, Bettws-y-Coed.*

Thalictrum dipterocarpum.—I have seen many references to this plant of late. My experience of it may be of some use to your readers. I have grown it for four or five years in ordinary soil with indifferent success, the flower-spikes never reaching more than about 3½ feet in height. Last autumn I put a dozen roots in a clump about 3 feet in diameter in a border on the north side of a tall hedge. The soil had been made up for Ferns two or three years ago, and a quantity of rough forest peat dug in. The result has surprised me. This season the plants

have bloomed continuously for two months and have varied in height from 6 feet to 8 feet, the upper 3 feet or 4 feet being a mass of the beautiful and graceful flowers.—P. E. WALLIS, *East Grinstead*.

Caultheria trichophylla.—This has been a failure for the first time since 1898. There was a small crop of berries in June, but I felt certain of a good crop in August. Not half-a-dozen berries have ripened. There is still time for a third crop early in October, as was the case in 1913, but at present there are but few flowers.—E. CHARLES BUXTON, *Coed-Derw, Bettws-y-Coed*.

Bornmueller's Meadow Saffron.—I found a clump of *Colchicum Bornmuelleri* with some fully-open blooms in my garden on September 4th. It is one of the earliest and largest of the species, and has handsome Tulip-like flowers which open almost white and pass off to purple with a white zone at the base. *Colchicum Bornmuelleri* ranks practically with *C. speciosum* and *C. giganteum* in point of size, but is generally rather dwarfer.—DUMFRIES.

Prostanthera lasianthos, a native of Australia, is now at Rostrevor House some 13 feet high, and is a sheet of bloom. It is a handsome evergreen with sweet-smelling leaves, flowers, in closely-packed clusters, white, each the third of an inch across, with purple-marked throat. It was at first planted against a south wall, but it grew so vigorously that it was soon moved to a place under the shelter of some large Laurels, most of which have now been cut away, and those that remain serve to screen it from cold winds.—*Irish Gardening*.

Colchicum autumnale superbum.—Under this name a handsome Meadow Saffron was sent me from Holland some years ago to see if it was the same as one I grow as *C. veratrifolium*. It is not the same, but is a very ornamental *Colchicum*, superior in every way to the ordinary *C. autumnale*. The flowers are larger, of greater substance, and borne on much sturdier tubes. The colouring is also softer and more attractive, being a pretty pink with more delicate shading. It was first noted in flower this year on September 8th.—DUMFRIES.

Colchicum Bertoloni.—Under this name I have long had a small-flowered Meadow Saffron which blooms early. It comes nearer *C. autumnale*, the common Meadow Saffron, than any other I have, and does not appear to differ greatly from it. The flowers are a little bigger and appear some time before those of *C. autumnale*. This year, in a rather shaded position, *C. Bertoloni* opened a day or so after *C. Bornmuelleri*. The blooms are whitish with a tinge of purple. Its defect is its long tubes, which make the flowers liable to injury in bad weather.—S. ARNOTT.

Phloxes in a Scottish village.—There are few places in Scotland where gardening is more generally practised than in Moniaive, a charmingly situated village in Dumfriesshire and quite near the Maxwellton Braes of Robert Burns. A notable feature is the number of flowers grown in the front gardens. Some of these are mere fringes to the street, but the most is made of them. On a visit to Moniaive the other day I was struck with the extent to which the late-flowering Phloxes are grown in these front plots. Some of the best of the late Phloxes, though unnamed, appeared to be among them, and a good variety of colour was seen. A good white was frequently met with, these Phloxes helping greatly to give these street gardens brightness and interest.—S. ARNOTT.

Seedling Asters.—Another lesson as to the desirability of ruthlessly destroying seedling Michaelmas Daisies has just been learned. A few seedlings which escaped the hoe in the spring of last year were noticed when in bloom during the autumn. Certainly there was nothing new in the way of colour among them, but as they were of a neat, dwarf habit—about 15 inches or slightly less—it was thought that they might be useful in certain places where the taller Asters could not be accommodated. During the present season they have lost their dwarf habit, being between 3 feet and 4 feet in height, and they will, therefore, be discarded after they bloom.—W. McG., *Balmoe*.

The Ceanothus is one of the most beautiful of autumn-flowering shrubs. Specimens in these gardens that were flowering well in July are still objects of great beauty, and unless injured by frost will continue in bloom for some weeks to come. There are numerous varieties, of which *Gloire de Versailles* is still one of the best. This variety is quite hardy in this locality. In very cold districts it requires the shelter of a wall. This plant is seen at its best when grown in a group. Specimens grown in pots may be planted at almost any season, but the next few weeks are probably the best time of the whole year in which to plant. The ground should be well prepared by deep treuching and manuring.—F. W. GALLOP, *Lilford Hall, Oundle, Northants*.

Scabiosa pteroccephala.—This neat little rock plant is now (end of August) in full bloom, the pale mauve blossoms very pretty against the hoary foliage. It is of semi-prostrate habit and looks well in a sloping pocket in a sunny position on the rock garden, and is of quite easy cultivation in well-drained gritty soil. Its chief danger seems to be from winter wet, the unfavourable conditions of last winter proving too much for one or two of my plants. Most of them survived, and now look as healthy as ever. I think that in a London garden it is not only the damp that is harmful, but the soot clogs the pores of the leaves and does the mischief. It is a marvel to me how so many alpine plants seem indifferent to the uncongenial conditions of a London garden.—W. O.

Eucryphia pinnatifolia.—This beautiful shrub is described at p. 453 as "fairly hardy, though there are many places in the southern midlands where it grows well." It is, however, much hardier than this description might lead readers to suppose. The climate of Edinburgh is far from genial, but there is at present in the Royal Botanic Gardens there a fine group of half-a-dozen *Eucryphia* 7 feet or 8 feet high covered with blossom. Like so many southern Chilean shrubs, it relishes the humid atmosphere of our western seaboard, the finest specimens I have ever seen being at Pottaloch, in Argyllshire. *Eucryphia cordifolia* is less hardy than the other, but it is flowering well here in the open border, and has reached a height of 8 feet without any protection.—HERBERT MAXWELL, *Monreith*.

—This, which was recently referred to in GARDENING ILLUSTRATED as thriving so well in Kent, used to form a delightful feature on the basin-like slopes of the Coombe Wood nursery. One particularly fine specimen, raised, I believe, from seeds sent home by Richard Pearce, by whom it was introduced, was each season a mass of its charming blossoms. Its distinct character, as well as the fact that but few shrubs are in bloom when this is at its best, are great points in favour of this *Eucryphia*. True, in some districts it is

difficult to establish, but at Coombe Wood, where the first plants were raised in this country, it certainly gave one the impression of being quite at home. In its earlier stages this *Eucryphia* is benefited by a fair proportion of peat in the soil, while it very much resents lime in any form. It must not be allowed to get dry during the summer, and, in common with all Chilean shrubs, it appreciates a liberal amount of atmospheric moisture.—W. T.

The Cornish Heath (*Erica vagans*).—This is lovely in the rock garden now and is covered with flowers. It flourishes in my London garden in a bed made up of well-decayed leaf-mould with plenty of sand mixed with it and is very showy when in full bloom. Like most of the Heaths it can be easily propagated by pegging down the growths and sifting some sandy soil among them. After a few months the stems will be found to have emitted plenty of rootlets, and when these are sufficiently advanced the plants can readily be divided. As the rootlets are very fine care must be taken when moving that they do not suffer from being allowed to get dry.—W. O.

Pyrus Vilmorini.—This is one of the newer kinds of *Pyrus*, for it was only introduced to this country about eleven years ago, although it had been known in France some fifteen years before. Belonging to the *Sorbus*, or Mountain Ash, section of the genus, it is known as a small tree or sometimes as a bush with elegant pinnate leaves, peculiar by their winged mid-ribs and tiny, blue-green leaflets. The white flowers, borne in rather large heads in June, are succeeded by showy red fruits which ripen in August. Its native country is China, where it is said to grow up to 20 feet high. Here it is inclined to branch freely whilst small, and to form a bush rather than a tree, some attention to pruning being necessary in order to encourage it to add to its height. It might well be used as a lawn specimen in a position where a vigorous-growing subject would be out of place, and it is one of those species peculiarly adapted for small gardens. It should be given good loamy soil and be increased from seeds whenever possible. From its present appearance and behaviour it promises to be one of the most useful of the newer species of *Pyrus*.—D.

Tying up shoulders of Grape bunches.—The shouldering up of bunches of Grapes, referred to by "Kirk" on page 448, is often carried too far. No doubt by spreading out the bunches to their fullest extent they look much larger than they otherwise would do, but the bunches are far from pleasing when laid on the dish. I do not go so far as to say that no bunches should be shouldered, as in such varieties as *Barbarossa*, *Trebbiano*, and such-like shouldering must be practised if handsome bunches are to be obtained. Occasionally a few bunches of other kinds, such as *Muscat of Alexandria*, or extra large bunches of *Black Hamburgh* may be improved by a little judicious shouldering. What I like to see are nice tapering pyramidal bunches, all the ugly shoulders, if any, having been previously removed. It takes a lot of courage to remove portions of clusters of bunches, but growers who practise it never have any fear on this point, knowing full well that those portions which have been removed add neither to the symmetry of the bunches nor the look of the crop when finished. All the ugly shoulders should, of course, be removed just as the bunches are being formed, thereby throwing all the strength into the main bunch.—P. T.

TREES AND SHRUBS.

VIBURNUM DAVIDI.

This very distinct Viburnum was sent from China by Mr. E. H. Wilson about fourteen years ago. *Viburnum Davidi* will apparently never grow very tall, for, while increasing fairly rapidly in width, it grows slowly in height, some of the oldest plants in the country being at present less than 2 feet high. Its evergreen leaves are marked with three prominent veins, which run the whole length of the leaf. This distinct veining can be well seen in the accompanying illustration. The individual creamy-white flowers are small and borne in flattened heads, each about 3 inches across, during May and June, the inflorescences being very stiff and erect. They are followed by small fruits, which are blue when ripe. In China the fruits are said to be a very conspicuous feature, but so far, although borne regularly, they have not been seen

Part of a bush of Viburnum Davidi.

birds. It is very suitable for large and small gardens, and rarely fails to fruit freely.

CLOTHING BARE SURFACES UNDER TREES.

REPLY TO "ARBOR."

As regards the results obtainable from this kind of planting, a good deal depends upon the nature of the shade, its density, and duration—points which should be considered before deciding what to plant. In the case of evergreen trees it is of but little use to plant anything but Ivy to carpet the ground under them, and as much light and air as it is possible to secure should be allowed to reach it. In planting under deciduous trees there is much more prospect of securing satisfactory results, provided the branches do not come nearer than 6 feet to 8 feet of the ground. If they should come lower than that it is advisable to cut them off. Of all deciduous trees the Horse Chestnut is

the spring and summer receive as much water at the roots as will keep the soil about them moist. Where only one kind of plant is required there is nothing better than Box. Plants of this, about 2 feet high, that have been grown in an open position, are the best. They must be planted rather thickly, as they will not grow very fast. In such positions Box is more inclined to get bushy than to increase in height, unless drawn up by surrounding subjects. In most cases a mixture of evergreens will have the best effect. The following will succeed under trees as well as one could expect—viz., Aucuba, Euonymus, Laurustinus, Yew, Rhododendron ponticum, Berberis Aquifolium, Box, green Holly, Butcher's Broom, common Laurel, and Portugal Laurel. In order to secure a carpet of greenery under trees the St. John's Wort answers fairly well if the shade is not very dense. The most satisfactory plant for this purpose is the Irish Ivy. For this the ground should be prepared in the same manner as for evergreen shrubs; and, as growth is made, it should be pegged down until the surface is covered. Where it is not desirable to plant anything of an evergreen character under trees that stand in isolated positions on lawns the ground beneath them may be made to have a cheerful appearance in early spring, before the leaves expand, by planting the space with bulbs, such as the Winter Aconite, Snowdrop, and Crocus.

FRUIT.

WARTS ON VINE-LEAVES.

COMPLAINTS come frequently from those who have not had much experience in Grape culture about the prevalence of warty-like excrescences upon the under sides of the leaves. This is the effect of one of the errors—too much moisture—in the treatment of Vines which amateurs commit. Especially in the case of young Vines is it more noticeable. Vines which have their foliage covered on the under side with warts cannot perfect a crop of Grapes so well as those which have their leaves free of such unnatural excrescences. This defect in growth is the outcome of too much moisture upon the leaves and atmospherically. In the latter form the mischief is most generally committed, although in conjunction with an insufficient supply of fresh air. Amongst cultivators generally it is a rule to damp the surface of the borders, paths, walls, and stages, if there be any inside the house, twice daily, and in some instances oftener. This treatment is all very well when judiciously carried out—that is, when the days are bright, so that an abundance of air can be admitted to the house without unduly cooling the temperature; but loading the inside of the house with moisture when the outside elements do not admit of sufficient fresh air being admitted causes the formation of the warts. In the case of new vineries, or even old ones, where the Vines have just been planted, many persons make it the rule to thoroughly drench the foliage twice daily during the time growth is active. This treatment may be correct when the weather is hot and the outside atmosphere dry, but when the atmosphere is loaded with moisture, and but little of the sun's power felt, then the daily syringing twice, or even once, is a mistake. Grape-growers who are year after year successful, study the appearance of the weather daily before determining the treatment the Vines shall receive for that day, as upon this point depends much of their success. A superabundant quantity of atmospheric mois-

at their best here. It thrives in good loamy soil to which a little leaf-mould has been added, but should be given a position sheltered from cold winds. D.

The American Mountain Ash (*Pyrus americana*).—Lovers of trees that bear brightly-coloured fruits would do well to make a note of this species, for its fruits are in every way as ornamental as those of our native Rowan or Mountain Ash, and, if anything, they are borne in larger clusters. The tree is widely distributed in eastern North America, and was grown in the British Isles as long ago as 1782. It never grows into a large tree, for its average height in America is given as 15 feet to 25 feet, and in this country it does not attain the larger size very quickly. As a rule, it is more pyramidal and denser in habit than the British tree, whilst it has much larger buds, which have sticky scales. The white flowers are produced in dense heads in May, and the coral-red fruits are ripe in August, remaining on the trees for a considerable time if protected from

the most injurious to anything growing under it. The Beech, the Elm, and Sycamore do not seriously affect undergrowth more than might be expected from the dense canopy of foliage with which they are furnished in summer.

In dealing with spaces under deciduous trees which have attained a large size, and filled the soil, even to near the surface, with roots, it will be necessary to make the soil as suitable as possible for the reception of the plants to be put under them. It will do no injury to the trees if the surface is broken up from 4 inches to 6 inches deep. When this is done, some fresh earth should be mixed with the surface soil, for it is necessary to give the undergrowth a bit of good soil in which to start. The trees, too, will derive benefit from the new soil. Once the undergrowth gets hold of the soil it will take care of itself as well as the circumstances under which it is placed will allow. The best time to plant evergreens under trees is, doubtless, early in October; if the work is done later the plants should all through

ture inside anyinery must be avoided. Moisture is necessary for the life and success of the Vines in perfecting their crop of fruit, but it should be given in such a manner as to be easily balanced by a judicious supply of fresh air.

The first thing to do when Vine-leaves are affected with warts is to check the supply of moisture in the air by damping down the borders only when the weather is bright, and this but once daily, preferring the afternoon at the time of closing the house. Air should be admitted very early in the morning, when the temperature reaches 70 degs. When the temperature is allowed to rise to 80 degs. before any air is given, the air in the house becomes stagnant, and is not conducive to a healthy growth of the Vines. The pores of the leaves become so gorged with an excess of moisture that assimilation is hindered to a certain extent, the result being warty foliage. If the atmosphere outside is loaded with moisture it is the height of folly to do likewise in theinery. By equalising the supply of moisture and heat in theinery—both very necessary matters in Grape culture—Vines affected with warty foliage can be cleared of these excrescences in the future growth. It is not possible, perhaps, to rid the present leaves of the warts when once thoroughly affected, but the after growth can be made perfect by a judicious application of air to the house, aided by the proper regulation of moisture.

LIFTING PEACH-TREES.

REPLY TO "INQUIRER."

EARLY lifting of trees is not favoured by some, but it is useless to wait for the leaves to fall if the best results are expected next season. No matter how carefully one plants Peach or Nectarine trees, with good culture gross wood results, and this grossness is better counteracted by lifting than any other plan—that is, if due attention is paid to extension. In good loam the trees invariably run to wood, and as one is anxious to fill a large space as early as possible, a check during the growth of the trees is not given by stopping. In such cases lifting may be described as the remedy. By proceeding cautiously there need be no fear as to loss of crop, and the health of the tree will be assured for the next four or five years. If care is taken to preserve the fibrous roots no harm will follow. When lifting, care should be taken to keep at a good distance from the trees, and in the case of Peach-trees in early houses lifting should be done early in September. It is a very good plan to damp the lifted trees overhead in the evening, as this keeps the buds plump and enables forcing to be done more readily the next season. With large trees it is not necessary to remove every particle of soil. Allow that adhering to the fibrous roots to remain, provided the weight does not break the latter. The preservation of fibrous roots is an easy matter if room is allowed at the start to get round them. All large roots may be cut clean off at a fair distance from the tree, and if the roots are inclined to descend, planting higher is beneficial. Manures of any kind should be omitted, good turfy loam well rammed or trodden being essential, and in clayey soil some mortar, brick rubble, or road scrapings is a valuable addition.

By this early lifting, severe cutting back, often the cause of canker later on, is avoided, and the trees can be forced the next season if not subjected to excessive night temperatures at the start. In the case of trees on open walls and that are required to fill up gaps, early lifting is advisable, as by so doing the root action

continues so long as the leaves remain, if these are assisted by frequent dampings to preserve vitality and encourage new root growth. After lifting no tying should be done till the trees have well settled down.

NEGLECTED PEAR-TREES.

AGAINST the house are some large Pear-trees, none of which are less than twenty-five years old, and some are very much older. The judicious pruning of these has for years been neglected, in consequence of which they required a lot of hard pruning, especially so, one very old tree, which has not borne fruit for several years now. The fruit-bearing shoots from the main side branches of this tree had formed very large gnarled and knotted round ends, which gave innumerable small shoots bearing a lot of leaf, but no fruit or blossom. In February last I cut out some twenty of the largest of these knotted ends, leaving where I could an inch or two of the branches (which were here $\frac{3}{4}$ inch to 1 inch in diameter) where they joined on to the main side branches. In other instances I cut away these branches close to the branch from which it sprang. The other fruit-bearing shoots on the tree I also pruned back as much as I dared as I was afraid of doing too much in one year. Again, towards the end of July, I pruned back all the new shoots, leaving five leaves to each shoot, which will have to be pruned back eventually to two. My difficulty now is that the shoots which I have trimmed back to five leaves have shot out again in a wonderful manner, forming a new shoot from the topmost bud, and are now some 18 inches to 2 feet long (new since July) on top of the first shoots of this year. I should be much obliged if you would kindly let me know if I should now prune back the new shoots once more or should they be left till February again? If they are to be pruned once more, should I prune them right back to within two leaves of this year's first new growth (where eventually they will have to be pruned) or only prune a portion (if so, how much?) of this year's second growth, leaving the final pruning to within two leaves of this year's first growth till February next? The chief offender in the way of long shoots is the very old tree from which I cut such a number of big, round, gnarled clumps. I could have cut away as many more of such growths with advantage, but I was afraid of killing the tree if I did it all at once. Ought this to be treated the same way next year? From where I cut away each clump some five or six new shoots have sprung out, which are amongst those that have already been pruned back and require another pruning. They are thin growths, however, and several of them will have to be cut out next February so as only to leave two shoots, as the tree has gone very much to wood.—F. H. HANCOCK (Colouel).

[The secondary growths or the young shoots you refer to in your note should be cut back to one bud without further delay. The pruning away of the remaining portion, together with the piece of wood on the first growths, which are now spurs, below them, can then be done any time towards the end of October or early in November. This would be a far better course to pursue than waiting till February next, as not only will the wounds heal before winter sets in, but the lowermost buds, or some of them, will plump up considerably during the winter, and in course of time, say during next summer, will become transformed into flower-buds. We would also advise you to leave the spurs longer than you propose doing, as, seeing the trees make such vigorous growth, it is quite possible that both buds, if you do shorten them as intimated, will start into growth and jeopardise all possible chances there may be of obtaining a certain number of fruit-buds on the spurs next season. If you cut these spurs back to the fourth bud or leaf, as advised, you will find that one, or at the most two, only of the buds will start into growth next spring, while the remaining two below them will be gradually transformed, as has already been

mentioned, into flower-buds. Provided that summer and autumn pruning, especially the former, is conducted on the same principles next year, a good quantity of these same buds should result the following year. With regard to the groups of shoots produced as a result of shortening back of subsidiary branches, you may cut clean out all that are not required at once. If any of these are wanted for extension leave them, if not very vigorous, about one-third their total length when shortening them. You have acted quite right in not doing the requisite amount of branch-thinning in one season. This is best spread over two, and in the case of very neglected trees three, seasons.

When sending queries please write on one side of the paper only.]

Diseased Peach foliage (P.).—The Peach-leaves sent show evidence of a severe attack of red-spider, which has sucked the sap from the leaves, and left them in the condition yours are. Red-spider is a most minute insect, which fastens on the undersides of the leaves, and so exists on them. It is too late, we fear, to do much good now, except that you can give the trees a good washing with very strong soapy water. By forcing that on to the trees most of the brown leafage would fall. That should be at once gathered up and burnt. It would do your trees great good, no doubt, if you could, so soon as the leaves have fallen, take off all the soil down to the roots, replace it with some fresh, to which are added good loam, old mortar refuse, and a half-pint to 3 bushels of basic slag. That should cause the trees to make new surface roots, and if that were so, you would soon see the effect in more healthy growth. But as the wall and wood may still harbour the insects or eggs, you had better also, so soon as the soil renovation has been done, have the trees sprayed with the caustic soda and potash solution, giving them a second spraying in January. That should destroy all insect pests. It is very possible that the glass coping, which, we assume, projects somewhat, keeps the trees too dry. Better remove the glass coping entirely.

Renovation of Vine and Peach borders.

—This can now be undertaken in all cases where the crops have been cleared, and when such a measure is from any cause deemed necessary. Such operations require to be carried out with promptitude, therefore everything that will be wanted for the purpose should be in readiness beforehand. Whether the lifting is to be of a partial or total character the same care must be exercised in the preservation of the roots as they are laid bare and liberated from the soil. Damp Moss is as good as anything to cover them with when they are turned back and laid out in wet mats, and which should be occasionally sprinkled with water. Shading of the roof, both during and for a time after lifting has been completed, tends to prevent the foliage becoming too much distressed, while an occasional syringing of the latter will have the same effect. This, with keeping the structure partly closed for a few days, will help to tide the Vines or trees over such a trying ordeal, and at the same time induce the roots to quickly push out new fibres into the fresh compost. Top-dressing in connection with both inner and outer borders, where the trees or Vines, as the case may be, are resting, may now have attention. With the compost in readiness to put on, the work can be quickly accomplished, as it can be spread directly the old and inert surface soil has been removed to a depth of 2 inches or 3 inches, or as circumstances may demand.—G. P. K.

PLANTS AND FLOWERS.

ROCK, ALPINE, BOG, FERN, AND WATER GARDENS.

SILENE ALPESTRIS.

THE *Silenes* are a rather numerous lot, but the best of them, so far, is that shown here. It may be grown as an edging plant, and it is very free in all conditions, but I never saw it quite so happy as among the rocks at Friar Park, raised out of the way of competitors. Given the gritty soil it needs it is a bright rock plant.—W.

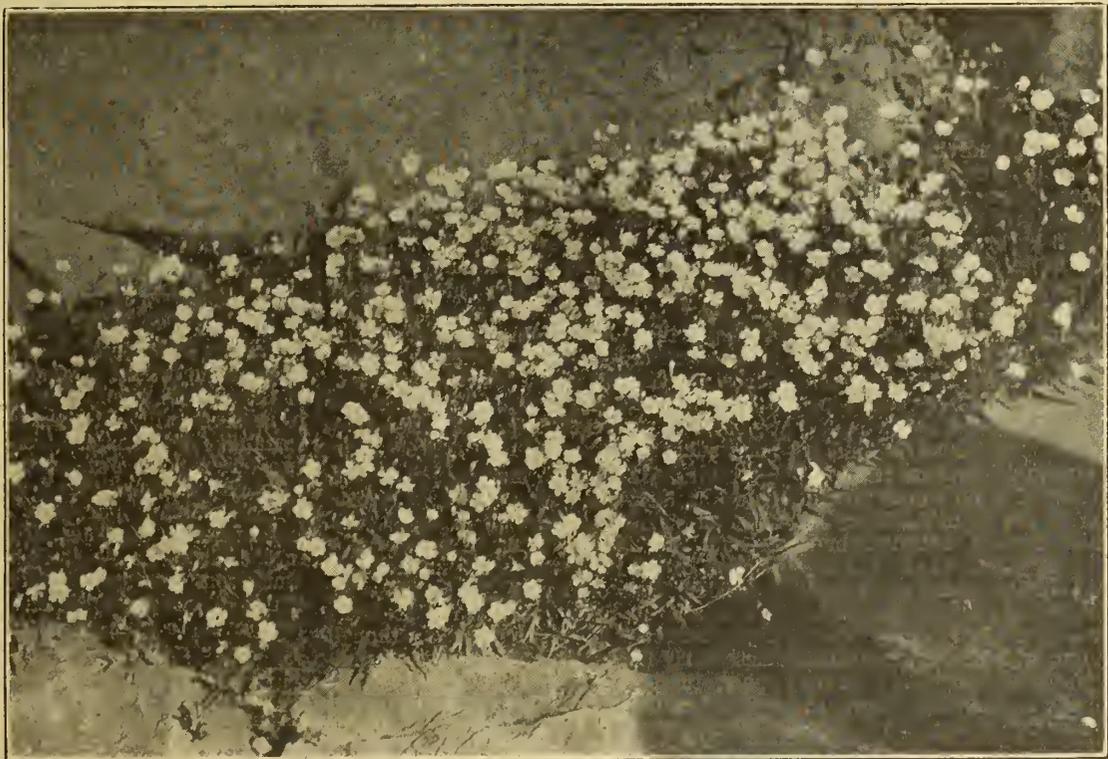

SAXIFRAGA OPPOSITIFOLIA.

It is curious and interesting that no two correspondents who have recently given their experience in reference to this valued group of alpiners agree as to their requirements, save, perhaps, in the matter of limestone, which may or may not be essential. The thing to do in such a case is to try and discover what suits

full exposure, while a combination of the two is almost sure to end in failure. Mr. Stuart Hogg pins not a little faith to the rock under which some of his plants root. Probably also the shade given by the rock assists not a little. His other group, flowering less freely, may, with mulching and moisture, give a far better account of itself, since all this tribe root in their onward course into cool or moist soils, and not less well into pure sand if moist and at, or below, ground level. This fact agrees with the view of Mr. Rogers that "it does not need lime." These notwithstanding, there is still the proof that lime is not distasteful to these plants.

Too frequently, perhaps, in recounting our failures and successes with plants, we are apt to regard them all too superficially, not taking into sufficient account the differences of locality, soils, altitude, rainfall, and other things which, unknown to us, must be playing a more or less important part one way or another. Surely something hinges even on the nature of

will be, for a further planting a little later. At Wisley, in the rock garden, there is a 6 feet long group a yard in width at the widest part. This is of the same mat-like growth and rooting as the group referred to above, and both are in a cool, sheltered position. Mr. Cornhill should see the Wisley example and note its position. The free-rooting and free extension of the rhizomes in this plant are proofs of its success, and as it invariably behaves thus when in cool or even moist surroundings there should be little difficulty in accommodating it. The example Mr. Cornhill "placed in a sunny position" was wrongly planted, and if dry also, as is the more likely, so much the worse. Why the "well-rooted pieces" also failed is not clear, and Mr. Cornhill gives no clue as to their subsequent treatment. Of this I am pretty certain, however, that had they been detached in September or thereabouts, firmly potted in sandy loam and leaf-mould, and given cold-frame treatment for a time, all would

Silene alpestris in the rock garden at Friar Park.

individual localities and then stick to it. The hundreds of plants in small pots that each spring are seen at Vincent-square would almost go to prove that frequent propagation—intensive propagation—plays an important part, since nothing could produce results more prodigal of flowering than these young plants. On the other hand Mr. Stuart Hogg and Mr. R. L. Reuth both get excellent results from examples not periodically divided, and certainly a 5-foot wide patch is something to boast of when in flower.

When growing quantities of the several varieties in pots in plunging beds it was frequently observed that the plants appeared to prefer the sand which constituted the plunging material to the soil in the pots, the escapes into the sand assuming a greater vigour and flowering in proportion. At the same time I know of instances where, in rather stiff, cool loam, on level ground over the red sandstone, the plant is a complete success. I prefer a cool rooting medium for the plants as opposed to one of dryness or

the water artificially applied, and which to some extent might be solved by the use of rain-water for some and the ordinary supply for others. The plant, happily, is not of an exacting nature, while its success in diverse localities and conditions should tempt many to grow it for its hardiness and abundant, as well as early, flowering. E. H. JENKINS.

NOTES AND REPLIES.

Ourisia coccinea.—In a note in a recent issue anent this fine plant I alluded to a planting I made of it a year ago, this comprising freshly-purchased stock in addition to that existing. That colony is now fully a yard square and so vigorous that, in the first week of September, it was flowering as freely almost as in June-July. Better still, and not content with matting the entire surface named, there were seen issuing on all sides numbers of the extending rhizomes bristling with root-fibres, each varying from 2 inches to 4 inches in length. Of such, a score or two might readily have been detached, and probably

have been well. Cool conditions at such a time are essential to success, the opposite invariably courting failure.—E. H. JENKINS.

The Mountain Avens (*Dryas octopetala*).—For continuous blooming this is hard to beat. It started to flower in May, and has gone on producing its lovely white Anemone-like blooms at intervals ever since. I think it is one of the choicest alpiners for the rock garden, its foliage, like little crinkled Oak leaves, being almost as charming as its flowers. It does quite well in a town garden.—N. L.

Silene sibirica.—Although only an annual, this species is very useful for the rock garden, as it sows itself about and comes up each year. I have one form with crimson flowers, and another with very pale pink, and both are beautiful. It only grows about 8 inches or 10 inches high, and is of quite neat habit, carrying its flowers in a close head.—W. O.

"The English Flower Garden and Home Grounds."—New Edition, 12th, revised, with descriptions of all the best plants, trees, and shrubs, their culture and arrangement, illustrated on wood. CHRYSANTHEMUMS.

SEASONABLE NOTES.

Now that the buds have appeared freely every care must be taken that their development shall progress unhindered. A check of any kind at this time will manifest itself in irregular bud development, and this will be most pronounced when the florets unfold later on. The buds that have been developing for the past month or six weeks are known as crown-buds, which usually give the better and larger flowers, and for exhibition, blooms resulting from any other type of bud are of little value. Most of the blooms that one sees at the "National" and other large Chrysanthemum shows are produced from what are known as second crown-buds, which not only yield large, deeply-built flowers of even form and beautiful colour, but their quality generally is better than that of those resulting from a first crown bud selection. All too frequently first crown buds produce blooms that are rather coarse, and usually their colour leaves much to be desired. Readers who are unfamiliar with the character of growth of the Chrysanthemum would, therefore, be well advised to retain all buds as they are now developed. Crown buds vary somewhat in their character. First and second crown buds are formed individually in the points of the shoots, and they are surrounded by short, fresh, young growths. These young shoots are very brittle, and should be removed by breaking them out, leaving the bud quite alone at the apex of the shoot. The bud is then secured or retained. From this point plants that have their buds retained should be grown on without a check. During the next week or two plants that have not had their crown buds retained will be producing their

TERMINAL BUDS. This kind of bud is described as "terminal" because it marks the termination of the plant's growth, and from this point in the plant's history no further growth is made. Terminal buds are developed in clusters of varying density. Some clusters contain quite a number of buds, while others have comparatively few. Terminal buds, when partly thinned out, will produce beautiful blossoms in sprays, so useful for many forms of decoration. Rather more interesting and pleasing, however, are those sprays of blossoms that are the result of clusters of these terminal buds reduced to about three good plump buds on each spray. If the buds be removed so as to leave the three set well apart, the blooms will open in charming fashion and give sprays of the most beautiful character in the late autumn and early winter. Plants treated in this manner usually develop into large and handsome specimens that for conservatory decoration and providing cut flowers cannot be excelled. In some gardens there is a great desire to develop fairly large blooms even from terminal buds, and this can be very easily brought about by retaining the largest and best looking bud and removing all the others in the cluster. I have a great liking for the flowers produced in this way. As a rule, on well-grown plants it is possible to get from twelve to eighteen blooms, each some 6 inches or more in diameter, and such plants have their uses in the greenhouse or conservatory, and as cut flowers they are invaluable. Colour is usually of the best in flowers developed from terminal buds, and the form of the blooms is also good.

The moister weather of late has caused the buds to develop kindly. Usually at this period excessive heat has induced

many of the buds to fail or go blind, but no such trouble confronts the grower at the present time. Growers should without delay see to the shoots being securely tied to the stakes. Neglect of this will assuredly result in the loss of valuable shoots, and when one remembers how many blossoms a single shoot of a decorative variety may carry in embryo the importance of carefully staking and tying the plants should be obvious. The growths should be tied out in such a manner that both sun and air may exercise their ripening influences. Unripened growth seldom produces satisfactory flowers. Should the plants be crowded in their standing ground thin out the plants in the rows, as they will benefit immensely by so doing. Keep the standing ground free from weeds and also see that weeds are not allowed to develop in the surface soil of the pots. Feeding of the plants should be attended to, being careful that the liquid manure is not given too strong. E. G.

VEGETABLES.

THE AUTUMN VEGETABLE SUPPLY.

The month of September reminds us of the approach of autumn. In many gardens where a little forethought has not been brought to bear there is often a very serious falling off of seasonable vegetables at a time when they can ill be spared, and it is very difficult to keep up an ordinary supply without encroaching upon those reserved for the colder season. With a fine autumn some of the ordinary summer vegetables will keep a long time in good condition and prove very welcome. Amongst these serviceable late crops may be mentioned French and Runner Beans, Globe Artichokes, late Peas, Cauliflowers, and Vegetable Marrows. All these are useful autumn vegetables, and when they fail suddenly they are much missed. The

RUNNER BEAN is a most useful vegetable for autumn, and as long as frosts keep off, or can be kept off, a supply can be had. A slight covering thrown over a portion of the crop upon the likelihood of a sudden frost occurring may perhaps be the means of their being saved for perhaps three or four weeks longer. Although these early frosts often come upon us suddenly, there is generally sufficient warning to enable a covering to be placed over. A heavy covering is not needed, a piece of tiffany being sufficient to ward off a moderate frost. Certainly this may not occur until the end of the month, if even then, but it is always best to be prepared. In the case of

FRENCH BEANS, frames are the best protectors, as these are easily placed in position, and the glass covering affords additional warmth—that is, where the rows have been arranged for the purpose. Covering with mats, or even waterproof canvas, will ward off a lot of frost, and should certainly be practised where a supply has to be maintained as long as possible. With late French Beans it is also very advantageous if the earliest opportunity is taken to place small spray sticks along each side of the rows, so as to allow as much direct light and sunshine as possible. By doing this and keeping the pods closely picked a good supply may be maintained until comparatively late in the season. Very often the latter part of September and the early days of October are very warm and bright, but in the case of French Beans it is not safe to leave them uncovered after the end of the month, and very often they need it earlier.

VEGETABLE MARROWS succumb to even a moderate frost, and although it would be a difficult matter to protect plants

covering a large surface, it is often easy enough to protect the best part of a plant or two either by mats, to be kept off the tops with suitable supports, or, what is better, a spare frame. At any rate, it is much the wisest if it can be arranged to protect even a plant or two, so as to be prepared against an emergency. In many gardens, especially those of a small size, such crops as Runner and French Beans with Vegetable Marrows are about all there is to rely upon, so in these cases it will be most advantageous to have some means of protection, or, at any rate, to be prepared in case of a sudden visitation.

GLOBE ARTICHOKEs also well repay a little extra attention at this season. At this time there is generally a quantity of smaller late heads showing, besides those from this season's planted suckers. If these can be secured from injury they will be found very acceptable. All that is needed is to place a few strong sticks around those it is intended to protect, so that a mat can be thrown over them upon the likelihood of a frost occurring. Old heads and stems which are still attached to the plants should be removed, as these, if allowed to remain, only draw the support from the later and succession heads.

VEITCH'S AUTUMN BROCCOLI is generally tolerably safe up till the end of the month, but after that it is best either to draw the tops together and tie them with a piece of matting, or have leaves laid over them, at least those that are showing heads. This is generally sufficient to ward off a moderate frost.

NOTES AND REPLIES.

French Beans.—If these are required through the winter a start should be made at the present time. The number of pots to be sown will, of course, depend on the demand. If this is of a continuous nature two dozen pots sown every ten days or a fortnight will maintain a sufficient supply for all ordinary purposes. Pots 7 inches or 8 inches in diameter, filled with a mixture of loam, leaf-mould, and a little old Mushroom manure, should be filled to within 2 inches of the rim, and in them sow seven to nine seeds, the latter number if the seed is old. These, when they germinate, should be thinned down to five, leaving, as a matter of course, the strongest. For the present the plants may be raised in a slightly heated pit, but as autumn advances a warmer place must be found for them. To grow them successfully after this stage is reached French Beans must have a light position and a temperature ranging between 65 degs. and 70 degs.—M. B.

Cucumber Lockie's Perfection.—After having grown many sorts I have come to regard this as one of the best for private use. True, it is neither a long fruit nor a new kind. I am growing it in a frame on a bed of leaves. When planted there was only about a peck of soil to each plant to start it, and this was of a light sandy nature from a fowl-run. This was put on early in June, when annuals were taken out. During the cold time their progress was slow, but when the weather was warmer they were damped over daily. This is the only water they have had. Nice fruits were cut early in August, and now—the end of September—the plants are bearing freely.—DORSET.

Mustard and Cress are sown in boxes as required. It is advisable to sow Cress about forty-eight hours in advance of Mustard on each occasion, the seeds of the former taking longer to germinate.

Lettuce.—Continue to transplant seedlings as they become large enough, and later they will need to be again transplanted into frames for the winter. The final sowing of Lettuces will now be made.

OUTDOOR PLANTS.

HARTLAND'S GOAT'S RUE

(*GALEGA OFFICINALIS HARTLANDI*).

I HAVE long known and admired in a mild way the Goat's Rues, but never knew how fine this was until I put it in my mixed border, where I was delighted with its beautiful midsummer effect. The illustration gives no idea of its delicate colour and fine free habit. W.

PLANTS FOR THE FLOWER GARDEN.

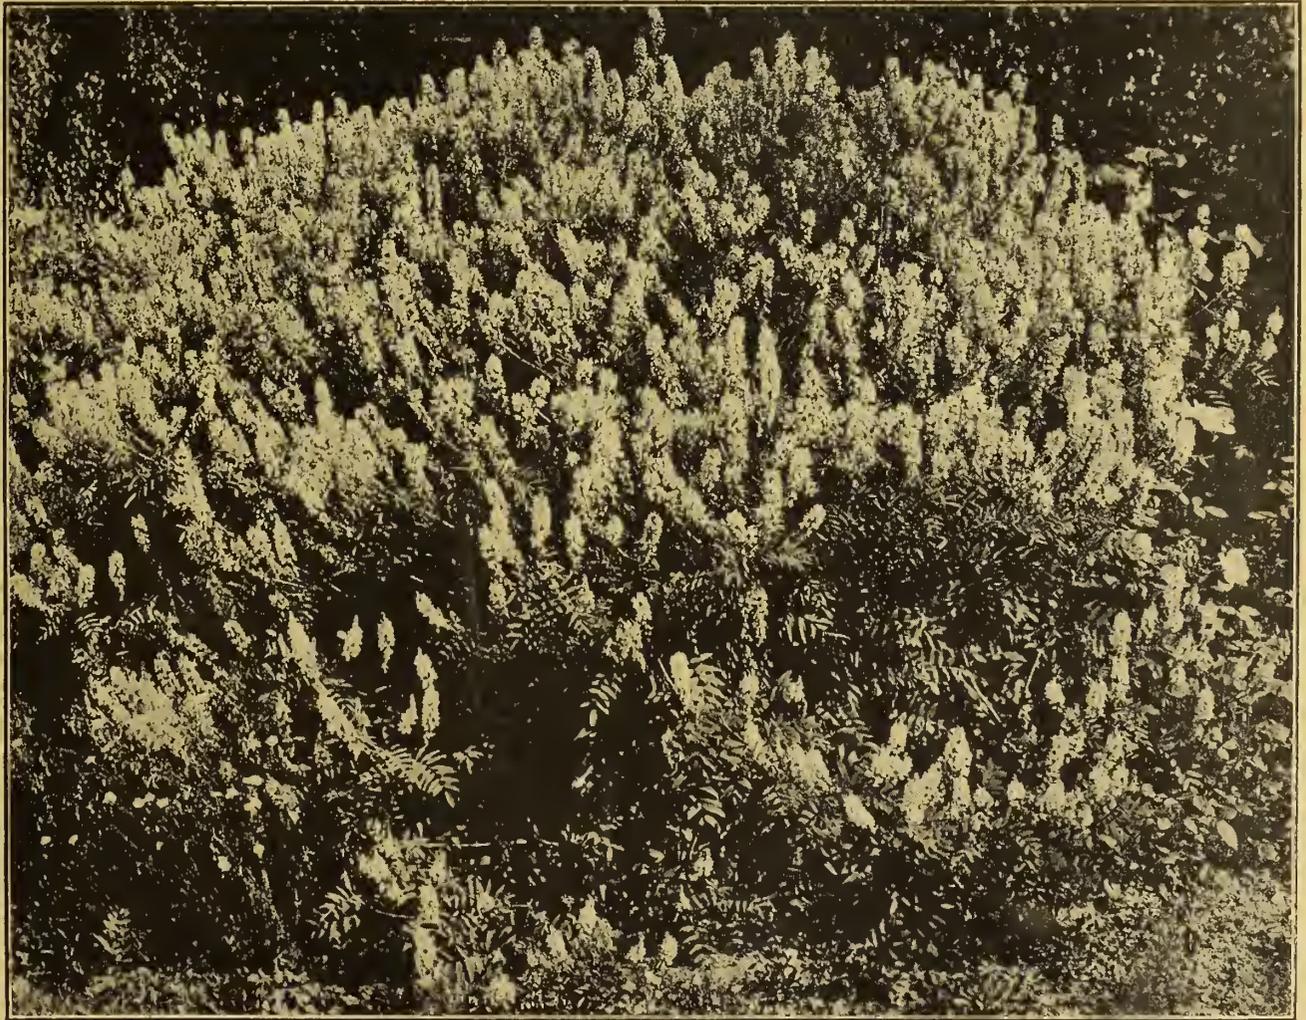

THE usual autumn work among the cuttings has, in the course of the week, claimed attention. It is not intended, during the present season, to put in such large quantities as has hitherto been the

tory from spring-sown seeds, so the practice of saving stock plants over winter has, for the present, been discontinued. Of course, the double Lobelia, Kathleen Mallard, cannot be propagated save by cuttings, so that a few plants of this variety must necessarily be kept. Although earlier than is absolutely necessary, in order to get the work finished, cuttings of the hardier things, like Tufted Pansies, Calceolarias, Pentstemons, and Marguerites, are being got in. These and such-like plants do quite well in beds in cold-frames, and may be put in comparatively thickly. KIRK.

LILIES IN 1916.

I KNOW not how Lily growers may have fared in Ireland this year, but in the

Sargentæ is following suit, and *L. Humboldti* has been overwhelmed; even the new and free-growing Lily, which I do not know whether to call *sutchucense*, *pseudotigrinum Biondi*, or *Wilmottæ*, has been overtaken just as the first blooms opened. Early-flowering species—namely, *L. umbellatum*, *L. pyrenaicum*, *L. Martagon*, *L. monadelphum*, and *L. pomponium*—escaped the contagion, though *L. Hansoni* suffered badly. *L. canadense* is perfectly healthy, but many groups of *pardalinum* have been affected. *L. testaceum* is good in parts, like the curate's egg, and so are its reputed parents, *L. candidum* and *L. chalconicum*. The excessive wet of last winter has destroyed many established bulbs. Gone is the peerless *L. Browni* from a bank which it graced for three

Galega officinalis Hartlandi at Gravetye; July.

case, but, at the same time, a sufficient number will be taken so that, if occasion arises, the stock may be increased by topping the plants in spring. Such things as Zonal Pelargoniums are put thickly into boxes which are made of a uniform size, so that when they are put into the pits in which they will be wintered no space will be wasted. Scented-leaved Pelargoniums are favourites, and are grown to some extent, so that, in the case of these, no diminution of numbers is practicable. For these, and similar cuttings, a light mixture is used, the soil is made fairly firm, and about 1/2 inch of sea-sand is placed on the surface. Meantime, the boxes are placed on a gravel walk in a well-exposed situation. Such things as *Ageratum* and *Lobelias*, which were at one time propagated from cuttings, are equally satisfac-

south of England and in the west of Scotland the present season has proved disastrous to their favourite genus. The summers of 1914 and 1915 were so favourable to the development of growth and blossom that we were deluded into the belief that means had been devised for averting or successfully combating the direst enemy of the race—*Botrytis cinerea*. But this year the most assiduous care has failed not only to prevent, but even to mitigate, the ravages of that fungus, and, most serious of all, species which we fondly imagined to be immune from its attacks have either succumbed or been badly disfigured. For instance, the splendid *Lilium regale*, after making excellent growth, and coming to the point of flowering, suddenly developed the fell blotches, and the blooms have been ruined. *L.*

consecutive seasons; *L. philadelphicum* has sent up but a few weakly, flowerless stems, and *L. auratum* has put in a very irregular appearance, except where the bulbs are protected by the roots of trees or shrubs.

It is a relief to turn from this dismal catalogue to contemplate the irrepressible vigour of *L. giganteum*, which only asks for liberal nourishment and cool quarters to defy disease and such enemies as mice and rabbits. The disappointment experienced by many persons in a first attempt to cultivate this—the easiest of all Lilies—arises from the dried-up condition in which purchased bulbs are generally received. No Lily is more easily transplanted when fresh, and the profusion with which the flowering bulb pro-

duces both seeds and offsets ought to ensure this fine species being grown far more commonly than it is.—HERBERT MAXWELL, in *Irish Gardening*.

SOME SUMMER-FLOWERING GENTIANAS.

G. ANDREWSII, a North American plant, remarkable for its blue flowers, which seldom open wide, produced in clusters on leafy stems about 18 inches high.

G. ASCLEPIADEA, one of the most robust, growing and flowering for many years, and forming large tufts. During the latter part of July and August the long, leafy stems, covered for the greater part of their length with beautiful blue flowers, reach a height of over 2 feet. If the ground is left undisturbed, self-sown seedlings come up freely round about the old plants, and soon a large colony is formed.

G. DECUMBENS forms rosettes of long, strap-shaped leaves, and produces decumbent branching stems 1 foot long, bearing at their tips clusters of blue flowers in July. The variety *mongolica* has mauve-coloured flowers. Both do well in deep rich loam in all but the hotter places in the rock garden.

G. FREYNIANA, a recent introduction, resembles the better-known *G. septemfida*, but is less erect in habit, and has larger flowers, more inflated towards the throat, while the fringed crest of the corolla is less prominent. The beautiful dark-blue flowers, with a paler throat, are produced in closely-packed clusters in July and August.

G. KURROO has the habit of *G. decumbens*, and is one of the most charming, its azure-blue flowers sprinkled with white spots near the throat developing in August and September. A sharp look-out must be kept in order to preserve it from slugs.

G. LAGODECHIANA, a recent introduction, grows in moist, stony soil at an elevation of over 7,000 feet near to the small town of Lagodechi, in the Eastern Caucasus. It is of prostrate habit, with ascending stems 6 inches or more long, each bearing from two to four short stalked, dark-blue spotted flowers in the axils of the upper leaves. They are nearly 2 inches across. The plant grows freely in well-drained, moist soil in a situation not too sunny.

G. ORNATA grows wild in the Himalayas and in Western China, and is extremely variable. The typical plant is of tufted habit, with narrow, fleshy leaves, many decumbent stems about 6 inches long, and each bears in September a solitary terminal flower of a charming turquoise-blue colour, marked on the outside with dull purple and buff-coloured stripes. It grows well in a cool, moist position.

G. PNEUMONANTHE is our little native Gentian, being found on boggy moorland in many parts of this country. It is about 6 inches high, bears deep-blue flowers in August, and is easy to grow in moist, well-drained soil.

G. PRZEWALSKII is a beautiful Chinese species in the way of *G. decumbens*, with more freely-branching stems bearing larger, lighter blue flowers in August.

G. SCABRA, a native of Japan and China, introduced about sixty years ago, has leafy stems, about 2 feet high, and is one of the latest to flower. Its flowers are dark blue with paler spots inside the tube.

G. SEPTEMFIDA is one of the earliest of this set, as it produces its bright blue flowers in June. It is variable, the stems ranging in height from a few inches up to 1 foot, with terminal clusters of lasting rich blue flowers.—*Field*.

CHRYSANTHEMUM FRUTESCENS.

(REPLY TO "PARIS DAISIES.")

Your experience as to the relative size of Paris Daisy blooms produced by plants grown in pots and in the open ground does not surprise me. The size of blooms produced by the London market growers in quite small pots would be a revelation to those who are only acquainted with this flower as grown in the ordinary way, either in pots or in the open ground. The market man brings his plants along quickly from autumn-struck cuttings, gets them into 6-inch pots in early spring, and as soon as the pots are full of roots and the buds are well formed starts feeding, so that the flowers are highly nourished from their infancy. When I first saw plants grown in this way I thought they were a new improved variety, for the blooms were quite the size of those of the Ox-eye Daisy of the meadows. Later on I found that I was mistaken, and that culture was responsible for the abnormal size of the flowers. I do not believe that it is possible to obtain blooms of such quality from plants in the open ground. I have just been looking at my plants. They are healthy and vigorous, but the flowers are only half the size that I have had them in pots.

The Paris Daisy is, naturally, very free of growth, and if the plants are well fed they make very rampant growth and in a damp time make foliage out of all proportion to the amount of flowers they produce. Your suggestion to sink plants in pots in the ground is, I should say, a very good one, and you would do well to give this plan a trial. I should not be surprised if you obtained blooms equal in quality to those furnished by plants in the Seakale-pots. I would try 6-inch or 7-inch pots as well as the larger receptacles. In the course of time roots will come out from the drainage-holes. The progress of these must be checked by twisting the pots round two or three times, otherwise they will begin to make rank growth. When *Etoile d'Or*, the yellow-flowered kind, came out some years ago I grew it in pots in a sunny greenhouse, and I have never seen such blooms since. I got the plants early in the year into 7-inch pots, and as soon as they became root-bound and flower-buds were forming freely I gave them weak guano-water frequently. Those plants were a mass of bloom. The colour of the flowers was very bright, and they were very large. One effect of so liberally feeding the mass of active fibres was that some of the blooms formed extra florets and became, to a certain extent, semi-double. I have often thought that I missed a chance then. I ought to have saved seeds from these blooms, and might have got a double yellow variety. As regards big specimens for exhibition some of the old plants could be kept and would probably do very well, but in the future I should propagate in early spring and grow the plants in the open air, picking off the flowers. They would come into 6-inch pots and would have a quantity of growths, and be in fine time for putting into 8-inch pots the following April. The leaves sent appear to be those of *C. frutescens*; the variety I have, under the name of *Halleri*, has narrower leaves, is more compact of growth, and produces more blooms in proportion to the size of the plants.

J. CORNHILL.

NOTES AND REPLIES.

Dividing-line in garden.—As a regular reader of your paper, I should be obliged if you would give me your advice. I have a very old Laurel hedge, about 7 feet high and about 4 feet wide, dividing flower garden from kitchen garden. It runs from north to south.

A narrow border, very damp and sour in winter, and very dry and caked in summer, getting very little sun, is on the east side of hedge. On west side, rows of Raspberry canes from north to south. The south end of border is much shaded by trees that cannot be removed. I am anxious to improve border, at least possible expense, and also to do away with the waste of room owing to width of hedge. Laurels are too old to be clipped back, as it would leave no green at all. Some shelter is necessary as well as screen between gardens. Would a strong Oak trellis, with posts, give sufficient shelter and support Roses and Clematis east side, and small cordon fruits or Loganberry on west side, or must I have palings? If the latter, where had I best procure them, and of what wood, and should they be creosoted all over, or will this harm plants?—*Mrs. A. L. PALMES.*

[*Get a woodman to cut down and burn the Evergreen Cherry (commonly and wrongly called the Laurel). Trench and well manure the ground, and plant a Holly hedge, using seedlings of the wild Holly. The Oak fence is a good idea, if Oak be plentiful in your district. Jarrah—an Australian wood—is said to make an enduring fence, but we have no experience of it. We prefer an Oak post and rail fence to the Oak palings, which are costly and not so fine in effect as the open trellis.*—*Ed.*]

Lilium Browni.—The illustration of this Lily in *GARDENING ILLUSTRATED* for August 19th shows what a fine plant it is when in a flourishing condition, but unfortunately it cannot always be depended upon. The plant shown is what must be regarded as *Lilium Browni* (true), that is to say the form so long grown in Holland under the above name. We are told by most authorities that *Lilium Browni* is a native of China, which may be correct, but at the same time the form so long known in cultivation does not appear to have been discovered by any of the recent collectors. Mr. Grove, in his book on Lilies, while giving the native country of *L. Browni* as Western China, states that *L. Browni* of gardens is not the same as the typical plant from Western China. Why this latter, of comparatively recent introduction, should be regarded as the type when *L. Browni* as grown in gardens made its appearance about 1830 I cannot understand. Undoubtedly there are several forms more or less closely resembling each other, and whose nomenclature is in a confused state. A. Grove, in *GARDENING ILLUSTRATED* (page 433), says that the true name of *L. odorum* is *L. japonicum colchesterense*. How this comes about I fail to see, for surely it is more nearly related to *L. Browni* or *longiflorum* than it is to *L. japonicum*, which is so generally known as *L. Krameri*. If priority of name stands for anything, *odorum* should be allowed to remain, for it is certainly far more widely removed from *L. japonicum* than is *L. rubellum*, which, on its introduction, was at once assigned specific rank. It may be said that the name of *odorum* is an inappropriate one, as there are many others equally fragrant, but the same argument might be brought forward for changing the name of *L. longiflorum*, which in length of flower is greatly surpassed by the more recently introduced *Lilium neilgherrense*.—*W. T.*

The Cup Plant (*Silphium perfoliatum*).—I saw a fine plant of this the other day in the interesting garden of Mr. J. A. Mather, Hastings Hall, Moniaive. Mrs. Mather is a devoted flower-lover, and, in consequence, many plants not met with every day are to be seen at Hastings Hall. *S. perfoliatum*, as seen there, was handsome, though, maybe, a little coarse. It

was fully the maximum height generally mentioned of 8 feet, and was a big bush bearing a number of its yellow Sunflower-like blooms on stout stems. *S. perfoliatum* is best in the wild garden or an odd corner where its bold habit will be seen to advantage.—S. ARNOTT.

GARDEN PATHS.

THERE is often something incongruous in the stiff Grass edgings of flower-garden paths, and this incongruity is specially emphasised by narrow strips of Grass which are intended to define a break between the garden path proper and any shrub plantations near. It is conceivable when a sharp rise in the ground behind necessitates a raised boundary of Grass to prevent soil being washed down over the path by rain-storms, but for no other reason ought Grass ribbons to be tolerated. They are obviously artificial; they do not improve surroundings; while

tration shows one of the many forms which may be adopted. When the path and steps were first made the edgings were formed by stiff, unnatural Grass lines, but now, by the introduction of various plants and the elimination of the Grass edging, a break has been obtained accompanied by fragrance and colour. It is also a curious fact that when plantations are carefully planned, in proper proportions to the surroundings, the result is never objectionable even when the plants are at rest. At their best they call for admiration; but when their beauty has faded they melt into the general surroundings of their environment.

Avenues and long walks are generally constructed in parallel straight lines of trees. Surely this method can be improved upon by means of breaks introduced by copying a natural design. Groups of the larger trees, not necessarily planted exactly so many feet from each other and from the edges of the avenue,

propagation and planting of the many different things to be found in hardy borders will rest with the demand. There are special favourites in most places both for the border display and for cutting, and these should be strengthened accordingly. If bulbs are grown on the general border it is not too late to suggest that their whereabouts should be marked with durable pegs before the autumnal alterations are put in hand. With the great wealth of hardy plants at our disposal we do not think, however, it is advisable to plant bulbs on the ordinary border, especially as there are few places where they cannot be naturalised on Grass either on a large or small scale.

The Basil-leaved Soapwort.—*Saponaria ocyroides* in autumn is always acceptable. The flowers vary much in colour from seed, but a deep rose-coloured form I have is again delightful, trailing over a sloping gravel bank and freely spangled with its bright flowers. *S. ocyroides* likes a dry position, and should not be too much exposed to cold winds in winter. I have frequently seen it go off in such places, but, happily, young seedlings often survive when older plants die, and in quite a number of gardens self-sown seedlings appear in considerable numbers.—S. ARNOTT.

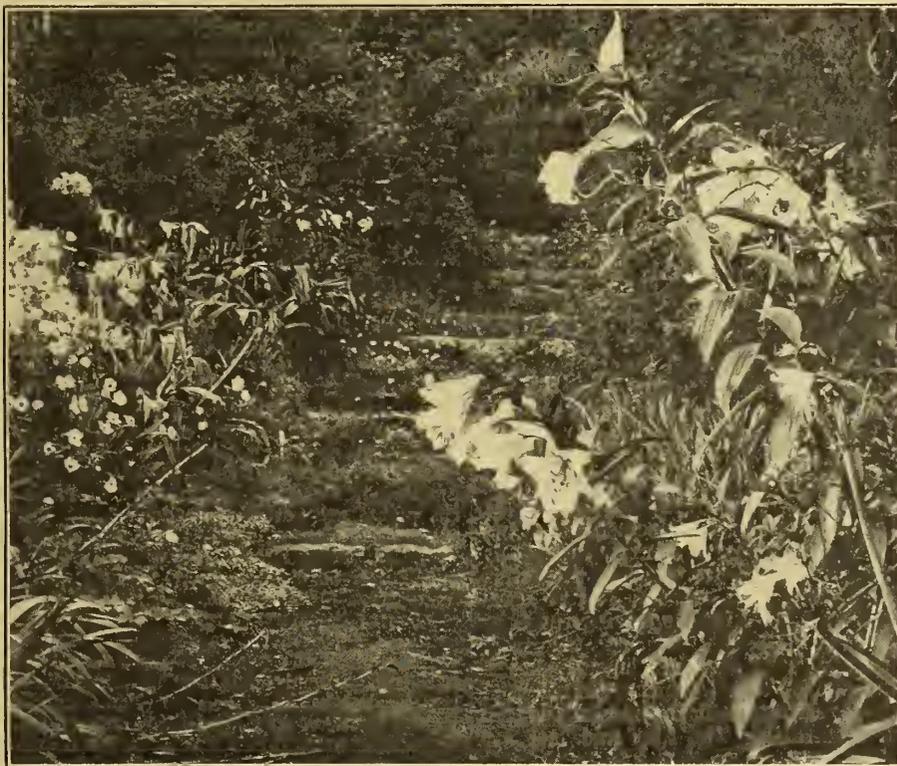

NATIONAL ROSE SOCIETY'S
AUTUMN SHOW.

SEPTEMBER 19TH, 1916.

THE holding of an autumn exhibition a year or two ago by the above-named Society obviously met a great want, and every year the event is marked by increased popularity. Before its coming the beauty of the Rose in autumn was lost to all but professional men and a few enthusiastic amateurs, the greater public knowing little about it. Its wealth and variety were, therefore, when seen, in the nature of a revelation, giving, as a result, a new impetus to the cultivation of the Rose. In this way the Society has done useful work, and gardens are richer and more beautiful because of it. The exhibition recently held, if not the best of the series so far—we thought that of last year of higher flower excellence—proved, to some extent, the exceeding wealth of the Rose at this season. Finer individual flowers, as just hinted, we have seen before, though never finer groups or banks. After all, the excellence or otherwise of an exhibition of this nature is very much at the mercy of the weather on the days—and nights—immediately preceding the show. These were, this season, by no means congenial to the development of the flower, hence such excellence as the show provided, and not a little its extent, came as a pleasant surprise.

The outstanding novelty of the occasion was the "Gold medal" "H.T." Christine shown by Messrs. S. MacGredy and Son, Portadown. Large and shapely, and of the richest orange-gold, it attracted everybody, its firm, glossy foliage and short-necked flowers being other points of importance. It is possessed of but a delicate tea perfume. Baldwin (H.T.), from the same source, is a smaller flower of deep apricot tone. It gained a certificate of merit. A like award was given Blush Queen "H.T.," shown by Messrs. Frank Cant and Co. It is of large size and very full. A single pink-flowered H.T., Mrs. Chas. E. Salmon, was also staged by Messrs. F. Cant and Co. It is attractive and free, but gained no award. Following are some particulars of the exhibits:—

Only one exhibitor, Messrs. D. Prior and Son, staged in the Nurserymen's Class for thirty-six distinct varieties. Of exhibition Roses such notables as William Shean, Lyon Rose, Candeur Lyonnaise (handsome white), Princess M. Mertchersky (a lovely pink selected for the silver medal), George

A garden path.

they only create unnecessary labour in mowing; as, in the majority of cases, these ribbons are made too narrow to admit of the use of a mowing-machine. In other words they constitute an objectionable feature and are a nuisance to the labourer who is supposed to keep them in order. Then, if paths are made sufficiently wide, in long paths at least 10 feet in breadth, the shrub or flower plantations which define them can form their own groups and curves, often erratic but always pleasing when the vegetation encroaches upon the sides of the path with reasonable irregularity thereby avoiding or breaking the two parallel lines formed by the Grass.

When observing long woodland paths we shall find that there is never any suggestion of regular parallel lines. On the contrary, they wander on sometimes broad and sometimes narrow, but always natural. Therefore the sides of our paths often require attention and thought, and their appearance can be easily modified and improved. The accompanying illus-

interspersed with smaller groups of shrubs planted irregularly, and not in circular beds, thereby defining shapes which should not be emphasised might be formed.

R. H. BEAMISH.

Hardy plants.—It is a good plan to note down in early autumn any alterations that are contemplated with hardy plants either on the mixed border or in separate beds. In the former case especially alterations are often necessary. The acquisition of superior varieties to those already in hand will lead to the removal of the one in favour of the other, whilst with new species mistakes are occasionally made in the positions originally assigned them in the matter of situation, in their relative heights in connection with other things, and the vigour of growth. The height can in many cases be regulated by stopping or pegging, but vigour is not to be denied, and strong-growing plants, if planted too closely to weaker brethren, are apt to interfere with the well-being of the latter. The question of increased

Dickson and Nerissa (cream) were remarked. The collection well merited and was awarded first prize. For eighteen blooms, like conditions, there were five exhibitors, the leading lot being presented by Mr. George Longley, whose H. V. Machin, Maman Cochet, and Charles J. Graham were good, the entire set very fresh-looking and clean. In the exhibition Tea and Noisette section Mr. Longley again took the premier award, five again staging collections. Alexander Hill Gray, W. R. Smith, and Mrs. Foley Hobbs (the last particularly good) were among the best. Messrs. Prior were second, the pick of their set being Mrs. Dudley Cross and Molly Sharman Crawford. In the class for twelve perpetual-flowering decorative Roses in vases the competition was keen, Mr. John Mattock taking first place and showing good-coloured flowers of Marquise de Sinety (golden-orange), Mrs. A. Hammond (pale pink), Ophelia (flesh and pink, shapely and very beautiful), and Mrs. G. Reid (cream and blush). Apart from good, well set-up flowers this exhibitor's produce appealed by reason of distinct naming, as great a help to visitors as to the Press, who usually have not too much time at disposal. Mr. George Longley was second, his vases of Alexander Hill Gray (cream-yellow) and Rayon d'Or being very fine. Mr. Elisha Hicks was third, his most notable variety, the single crimson Princess Mary, which is also delightfully fragrant. White Roses were chiefly shown in the single basket class for twelve blooms, one variety, these being Frau Karl Druschki and Candeur Lyonnaise, from Messrs. D. Prior and Son and Mr. Elisha Hicks, who took first and second prizes in that order. There was no competition in the class for nine baskets of Roses, which make so sumptuous a feast at the summer show, and only one exhibitor, Mr. Elisha J. Hicks, staged in that for five baskets. His lot comprised Joanna Bridge (a huge semi-double cream), Princess Mary (single crimson), Mrs. Dunlop Best (apricot), and those ever-popular varieties, Lady Hillingdon and Ophelia. The first prize was deservedly awarded.

The class for twenty-four distinct varieties of decorative Roses, not exceeding seven stems of each variety, brought two capital collections, the leading prize going to Mr. John Mattock for a most effective display. All were well set up in vases. Lady Pirrie (a lovely rose), Mrs. H. Stevens (a chaste and pure white), Old Gold, Trier (a cluster variety of great charm), Marquise de Sinety, Rayon d'Or (rich gold), and Louisa C. Breslau were some of the best examples. Messrs. F. Cant and Co., who were second, also showed Rayon d'Or, Lady Pirrie, and Old Gold, together with Carrie (a charming peach and cream combination), La Tosca, A. R. Goodwin, and Mrs. Alfred Tate.

GROUPS OF ROSES.

These were arranged on the floor at the western end of the Hall, and constituted a great attraction. Four exhibitors competed, the space allowed being 150 square feet. The first prize went to Messrs. George Paul and Son for an admirable lot in which many first-rate sorts were seen to advantage. Miss Alice de Rothschild (soft yellow), Ophelia, Lady Hillingdon, Mme. E. Herriot, Rayon d'Or (in splendid form), Mme. Jules Bouche (a creamy-white of exquisite form), Mrs. Edward Powell (rich scarlet, regarded as mildew-proof), Old Gold, Queen of the Musks (very pretty white), M. Jean Dupuy, and Constance (golden-yellow, an improved Rayon d'Or) were among those of outstanding merit. Messrs. Hobbies

were second, showing a considerable variety under a canopy of weeping standard Polyantha sorts. Mrs. Andrew Carnegie (very fine white), Pharisæer, Snow Queen, H. E. Richardson (rich red), Arthur Munt (ivory-white), and Lieutenant Chauré (very good red) were among many things. Mr. C. Turner, who was third, associated sprays of red-leaved Acers in vases with his flowers, the whole presenting a very pleasing effect. The representative groups of Roses arranged on tabling also constituted a good feature. In one of these (space allowed, 18 feet by 6 feet) three collections were staged, the Rev. J. H. Pemberton being placed first with an attractive exhibit, many of which were raised by him. Moonlight, Callisto, Danae, Clytemnestra, Daybreak (a pale Callisto), and Queen Alexandra (single white, which formed the centre) were the chief. Others included Comtesse du Cayla, Mme. Jules Bouche, Rayon d'Or, and Lady Pirrie. Messrs. W. and J. Brown were given second place, and we were not alone in the opinion that it was a long way first. In great variety and well displayed, it was decidedly the more "representative," a point upon which the schedule lays not a little stress. Prominent varieties in a large array included Lady Pirrie, Souvenir de G. Prat, Duchess of Wellington (rich yellow), the pure white Mrs. H. Stevens, and General MacArthur. As an exhibit of cut Roses it was the most representative in the whole show. On a space 20 feet by 4 feet there were also three exhibitors. In this class Messrs. B. R. Cant and Sons were well to the fore, staging such excellent sorts as Edu. Meyer, Harry Kirk, Lady Hillingdon, Irish Fireflame, General MacArthur, and Chrissie Mackellar. This firm alone staged in the class for thirty-six varieties, all classes of Roses being allowed. Here were seen such good sorts as Mrs. Foley Hobbs, Melody, British Queen (perhaps the finest white Rose grown), Lady Hillingdon, Earlate (a cluster sort of rich red colouring), Sunburst, and many others. Rose hips were a less attraction than we have seen on some former occasions, Mr. J. C. Allgrove having the finer exhibit and gaining first prize. The most meritorious were those having urn-shaped fruits, and of these, fruiting branches of Rosa Moyesi, R. setipoda, and R. Fargesii were remarked. The first and last are the most handsome, that last named the most brilliant in colour, the hips also freely spined. All are scarlet-fruited and distinct from each other. In the second prize lot, from Messrs. B. R. Cant, the variety Sheilagh Wilson, with big clusters of green hips was one of the most distinct.

LADIES' CLASSES.

The dinner-table decoration of cut Roses was a chief attraction, some ten tables being arranged with, for the most part, admirable taste and skill. The outstanding exhibit of them all, however, was that arranged by Mrs. L. Colston Hale, Warminster, who, with a delightful harmony in rose-pink and yellow—the former very sparsely employed—easily secured first prize. The varieties were Isobel (single rose-pink) and Golden Emblem, and we have but rarely seen anything so good or artistically done. Mrs. Tisdall, Woodford Green, with a handsome arrangement of Ophelia and sprays of Rosa rubrifolia, was second, and Mrs. A. C. Brown, Reigate, with a good table of Lady Hillingdon, third. An extra prize was awarded Mrs. Courtenay Page for her table, this lady securing first prize for a bowl of Roses, using Old Gold and foliage with considerable skill.

THE WEEK'S WORK.

OPEN-AIR GARDENING.

IN BLOOM SEPTEMBER 20TH.—*Abelia rupestris*, *Hardy Fuchsias* (in variety), *Magnolia grandiflora*, *Desmodium penduliflorum*, *Buddleia variabilis magnifica*, *Ceanothus* (in variety), *Calycanthus floridus*, *Wistarias*, *Clematises*, *Roses*, *Viburnum Tinus*, *V. coriaceum*, *Hydrangeas*, *Polygonums* (in variety), *Spartium junceum*, *Gyneriums* (Pampas Grass), *Veronicas* (in variety), *Astilbes*, *Hypericums*, *Rhus*, *Sambucus canadensis*, *Liliums*, *Tritomas* (in variety), *Gladiolus* (in variety), *Hyacinthus candicans*, *Asters* (*Michaelmas Daisies*) (in great variety), *Delphiniums*, *Enotheras* (in variety), *Helichrysums*, *Heleniums*, *Tree Lupins*, *Anemone japonica* (in variety), *Erigerons*, *Montbretias* (in variety), *Achilleas*, *Echinops*, *Lobelia cardinalis*, *Lavateras*, *Statice* (in variety), *Hollyhocks*, *Sidalceas*, *Linums*, *Coreopsis grandiflora*, *Dahlias*, *Thalictrums*, *Geums*, *Linarias*, *Verbena venosa*, *Francoas*, *Potentillas*, *Agapanthus umbellatus*, *Belladonna Lilies*, *Colchicum autumnale*, *Cyclamen hederifolium*, *Aquilegias*, *Pyrethrums*, *Pentstemons* (in variety), *East Lothian Stocks*, *Antirrhinums*, *Sweet Sultan*, *Nepeta Mussini*, *Salvias* (in variety), *Begonias*, *Cannas*, *Calceolaria amplexicaulis*, *Ageratums*, *Gazania splendens*, *Tufted Pansies* (in variety), *Carnations*, *Early-flowering Chrysanthemums*, *Annual Delphiniums*, *Scabious* (in variety), *Salpiglossis*, *Nigella*, *Anchusa Opal*, *Plumbago Larpentæ*, *Sedum spectabile*, *S. Sieboldi*, *Mesembryanthemums*, *Antirrhinum Asarina*, *Gysophylas*, *Tunica Saxifraga*, *Silenes* (in variety), *Clematis* (in variety), *Roses* (in variety), *Sweet Peas*, *Mignonette*, *Genista tinctoria*, *Clerodendron trichotomum*, *Cistus*, *Daphne Cneorum*, *Convulvulus mauritanicus*.

WORK OF THE WEEK.—A batch of the Poppy Anemone (*A. coronaria*) was planted during the week; another batch will be put in during October. By successive plantings the flowering season is considerably prolonged. The Poppy Anemone delights in a rich loam, with which has been intermixed well-rotted manure. If the soil is heavy, plenty of sharp sand should be mixed with it. *Belladonna Lilies* are now in their full beauty. Unfortunately, the plants are not perfectly hardy, but they succeed out-of-doors here at the foot of a warm wall. The bulbs resent frequent disturbance, but if it is required to increase the stock or make fresh plantings they may be taken up as soon as the flowers are over and replanted at about 1 foot apart (according to the size of the bulbs) in a rich, yet light sandy soil free from animal manures. Stimulants are best applied in the form of liquid-manure while the leaves and growth are active. The herbaceous borders now need a thorough overhauling, as a great many of the plants have finished flowering. All untidy flower-growths wherever possible should be removed. I do not advocate the too-early removal of all the old flowers, preferring to allow them to wither naturally. The rock garden requires frequent attention, cutting back any of the stronger-growing plants which have grown out of bounds, and top-dressing any that require it with suitable soil. F. W. GALLOR.

Lilford Hall Gardens, Oundle, Northants.

SOUTHERN COUNTIES.

Pot Strawberries.—As the pots are now full of roots, feeding with liquid manure or guano may be commenced. If judiciously applied, beneficial results in the shape of bold, strong crowns will follow. Runners and weeds must be persistently removed, and if the plants have a tendency to produce more than one crown, or a smaller one on either side of the main crown, these should be removed. When duplicate crowns are produced, as sometimes happens, take the weaker away. Rearrange and give the plants more space if necessary, and when heavy rains occur and the soil is moist enough, lay the pots on their sides till the weather clears. Evening syringing is now unnecessary, as the foliage invariably becomes abundantly bedewed during the night. On very hot days a good syringing about mid-day is beneficial.

Apricots.—The present is a good time to perform what pruning is necessary, instead of leaving it until winter. Spur-pruning may also be undertaken with far better results, as the pruner can see where the spurs are congested, and thinning is necessary more readily now when the trees are clothed with foliage than when bare. Another advantage gained is the fact that the wounds heal very quickly now, therefore gumming has not to be feared, as is the case when severe frost occurs directly after pruning in winter. In pruning, spurs which have grown out or project a long distance from the face of the wall should wherever they can be spared be removed first. After they are out of the way, the others can be more readily dealt with. The wood in spurs which are to be retained should, if crowded, be thinned out also. If given annual attention, the wood of Apricot trees can easily be kept close to the wall, and obtain the full benefit which the latter affords.

Apples and Pears.—The crops of both being anything but plentiful, the greatest care has now to be taken to preserve such fruits as the trees are carrying of maincrop and late varieties from birds. The "tit" family is the worst culprit in regard to Pears, but thrushes, starlings, and blackbirds work an incalculable amount of mischief amongst Apples when they begin to ripen and are full of juice, unless scared away by being shot at, etc., in all cases where it is impossible to enclose the tree with nets. Early maturing varieties of the codlin race of Apples may be kept for some little time after gathering if placed at the coolest end of the fruit-room. The same holds good with regard to Pears, such as Beurré Giffard, Beurré d'Amanlis, and Summer Beurré d'Arenberg. With regard to dessert Apples, Worcester Pearmain, though but second rate in regard to flavour, will in this season of scarcity prove valuable. This, fortunately, will keep in good condition for some time if not gathered before the fruits arrive at maturity. Nets should now be taken off Gooseberry and Currant quarters, dried, and if not further required folded up and stored away.

Indian Azaleas.—Should showery or very wet weather continue these will be the better for being taken in under cover, as too much moisture is injurious to the roots. A light, cool, and airy house must be accorded them if the flowering period has to be retarded as much as possible. In any case, it is best to place them in such a structure taking out the plants for forcing as wanted, beginning with the earliest varieties. Pick off dead leaves. Scrub the pots, and if there is the least suspicion of thrips on the foliage dip the plants in an insecticide, and syringe or dip them in clean water half an hour or so afterwards.

Camellias.—These, too, must be housed shortly. Although they do not suffer to the same extent from an excess of moisture as do Azaleas, too much of it might cause the buds to drop. If time admits, these should be well cleaned beforehand, especially if affected with white scale and smut on the foliage. A cool place is necessary for these; in fact, Camellias do very well in a structure facing north.

Chrysanthemums.—The earliest-flowering varieties should now be under cover and in many instances coming into bloom. The remainder—late-flowering kinds excepted—should now be taken in and arranged in Peach-houses and vineries when other and more suitable structures are non-existent, allowing as much space between the plants as is possible under the circumstances.

Schizanthus.—Seed of the varieties Wisetonensis and the large-flowered hybrids should be sown without delay, if the matter has not yet had attention. This sowing will supply plants for flowering in April and May next.

Bulbs for forcing.—Bulbs of such subjects as are under existing conditions obtainable should be potted or boxed in the usual way, and, after watering, plunged in Cocoa fibre or leaf-mould, where they should remain until they become well rooted. For early flowering, plunging in a frame or in a shed will expedite the rooting. The pots or boxes should in all cases be covered with at least 6 inches of the plunging material. A. W.

MIDLAND COUNTIES.

Fruit-trees in pots.—The present is a good time to look over pot fruit-trees. Any old unsatisfactory trees should be discarded. All pot-trees should be repotted annually. This necessitates a considerable reduction of the mass of soil and roots, so that they may be replaced in the same size pots, except in the case of young trees in small pots, which may have a size larger. Lime is a very necessary constituent in the culture of all stone fruits, so that a good percentage of old mortar-rubble should be mixed with the potting material, with a good sprinkling of wood-ashes, soot, and crushed bones. The trees must be placed in their new pots as quickly as possible after the roots have been disturbed. Pot firmly, taking care that the space between the ball and the side of the pot is quite filled with soil, using a very thin ramming-stick for this purpose. When potting is finished stand the trees, if possible, in a position sheltered from cutting winds. Thoroughly soak the soil with clear water, and syringe the trees two or three times a day during fine weather. Any pruning necessary should be done now, but if the trees have been attended to in the matter of disbudding and pinching during the summer, very little will be required.

Gathering fruits.—Most of the early varieties of Apples and Pears have been gathered. Later varieties are receiving attention as they become ready. Fine dry days are taken advantage of, as on no account must the fruits be gathered when damp. Every care should be taken not to bruise the fruits or gather them before they are ripe, or the colour and flavour will be impaired, and late varieties will not keep so well. Keep the fruit-room dark, opening the ventilators occasionally to carry off excessive moisture.

Pelargoniums of the show and fancy sections, cut back and started into growth as advised, are ready for shaking out and re-potting. Place them near the glass in a pit or frame, and keep close for a few days, shading from the sun if the growth flag. Scented-leaved varieties should now be housed, and, if not already done, put in cuttings to provide a stock of plants for next summer. Shoots of several of the varieties are useful for arranging with cut flowers.

Lilium auratum and L. speciosum are stood outside after flowering, allowing the stems to die down gradually and the bulbs to ripen, after which they will be potted up, using pots according to the size of the bulbs.

Late Peas.—The conditions at the time of writing promise a good supply of these for some time to come. The varieties Autocrat and Gladstone are doing remarkably well, and those in sheltered positions should continue to bear for several weeks. It is advisable to thin out the growths where they are very thick, and to pinch out the points of the leading shoots, while it will be of great assistance if the roots can be afforded copious supplies of liquid manure.

Cabbage.—Continue to plant as ground becomes vacant, and ply the hoe between those already planted.

Globe Artichokes should have all decayed leaves and old flower-stems removed and generally be made tidy. They frequently develop a good crop of their inflorescences during September, and these, provided they are uninjured by frost, are generally of excellent quality. The heads should be cut as soon as they are of a suitable size, whether required for immediate use or not. If the stalks are inserted in water and stood in a cool place, they will keep good for a considerable time. The finer varieties of Globe Artichokes are more tender than the coarser kinds, therefore from the best plants good suckers should be selected, at this season, potted up into 7-inch pots, and wintered in cold frames. If these are planted out early the following spring in rich soil they will produce a good crop of heads during the autumn.

Potatoes.—The whole of the Potato crop is now ready for lifting. Tubers intended for seed should be stored in trays in a cool, airy shed. Those intended for cooking will be placed in a pit after being well sorted. The

top of the pit should not be covered with soil for a week or two—till the surplus moisture has evaporated.

Cucumbers just beginning to bear will, under suitable conditions continue to give a supply to the end of the year. The growths must be well thinned out and only moderately cropped, removing each fruit as soon as it has reached a serviceable size. Be careful in the application of water to the roots and foliage of the plants. Another batch will now be planted to provide a crop for winter and spring supplies, using fresh turfy loam with a little leaf-mould and sand added. Allow the plants to grow well up the trellis before pinching or allowing fruits to form, after which they should be cropped lightly. Maintain a night temperature of 68 degs. to 70 degs., and a moist atmosphere. Syringe the foliage only on bright days. F. W. GALLOP.

SCOTLAND.

Potting having fallen somewhat into arrears was attended to in the early part of the week. A good batch of Gesneras, hitherto grown in 5-inch pots, three plants in a pot, were broken up and repotted singly into 5-inch pots. These will make serviceable stuff in December and January. The earliest batch is on the point of blooming—rather earlier than was desired, but they can be no longer delayed. *Libonia floribunda* has been moved from 5-inch to 7-inch pots. *Schizanthus Wisetonensis* for winter blooming is now in the flowering-pots, those 6 inches in diameter being quite large enough. Late-struck pieces of *Salvia rutilans* have gone into 5-inch pots. This variety is, I think, more useful in pots of this size than when grown in 10-inch pots. *Primula obconica*, *P. verticillata*, *P. einsensie*, and *P. malacoides* will bloom well in spring in 5-inch and 6-inch pots. So will *Alonsoa Wascowiczii* and *A. incisifolia*, the latter requiring some pinching to reduce the plants to a symmetrical shape. By way of a change, some plants of *Nicotiana glauca* will be grown. These are now in 5-inch pots, but will ultimately bloom in those 7 inches in diameter. I saw some plants of this last spring in 10-inch pots, and very handsome they were, being, however, two years old. I had not previously thought that the Tobacco plant would have succeeded for a second year, but the point is worth remembering. Arum Lilies were potted up. These, of course, may be had in bloom as desired, the time of blooming depending upon the temperature to which the plants are subjected. Herbaceous *Calceolarias* ought by this time to be in their store pots. Five-inch pots are quite suitable for these over the winter, and they should, if possible, be kept upon a shelf, well exposed to the light, and occasionally gently vaporised to keep aphid in check.

Greenhouses.—With the declining season the display is not so profuse, many subjects, although yet too good to be discarded, showing signs of exhaustion. If time permits, a weekly rearrangement will do much to increase the attractiveness of plant-houses. Dead or withered foliage and blooms should be removed at stated intervals—twice a week, if possible. If this detail is not attended to the spent blooms contaminate others, and are a fruitful source of damp, besides being a probable lurking place for insects.

Watering, especially in houses which are liable to damp, ought to be carefully done, and no more moisture than is absolutely necessary should be thrown about. Ventilate freely on all suitable occasions, shutting up at a fairly early hour in the afternoon. This conserves the solar heat, and although in the case of greenhouses fire-heat is not yet absolutely necessary, yet on especially cold nights or on unclouded days it is advisable to run a little heat through the pipes.

Stove.—Shading, if not already washed off by the action of the weather, should now be dispensed with. Plants ripening off should have their supplies of moisture gradually reduced until the maturing period is finished. Gesneras now begin to be useful, and fine-foliaged plants are always bright.

Hardy fruit is much later in ripening than usual, and Pears especially are not finishing so well as was at one time expected. Apples, too,

except on young trees, will be smaller individually, while Plums appear likely to be interfered with by the out-and-in weather which is preventing their ripening. Nets which have gone out of use were during the week taken off, dried, and labelled, and afterwards returned to store. It is always advisable to label nets at this time, as this practice, if followed, saves confusion when they are again needed. Each label is marked as to whether the net is in good repair or the contrary, so that if time allows during wintry weather they may be overhauled and repaired. The best pieces of old nets can be utilised for patching others of better quality, and it is a great advantage to have them ready for use when they are again required.

Vegetable garden.—In the course of the week Cauliflower seedlings were pricked off, while a number of seedling Brussels Sprouts was put out into a nursery bed. Spring-sown Onions are later than usual in maturing, but the ripening may be hastened by pulling the bulbs and spreading them out thinly in a sunny and well-exposed place, or, if a few cold frames are empty, if the Onions be laid out inside these they will ripen up more quickly. If labour is scarce the Onion bed, if dressed with soot and well hoed and raked, may carry a crop of Brassicas during next spring. Such things as Cabbages heart in more quickly if the ground is not too loose. Parsley seedlings, if a partially decayed hot-bed is available, will soon make way if put out thereon, and, while pickings may not be large from such plants during winter, there will be plenty of leaves in the early spring. Asparagus beds have received a final dressing of artificial manure. W. McGuffog.

Balmes Gardens, Kirkcudbright.

CORRESPONDENCE.

PLANTS AND FLOWERS.

Salvia patens (G. B.).—In warm, light soils, and where the local climate is not very severe, this plant may be safely left in the ground during the winter, taking the precaution, however, to place a good shovelful of ashes or Coconut-fibre over the crown on the approach of severe weather; otherwise it is safer to lift the roots carefully, pot or place them in boxes with some earth around them, and winter in a cool greenhouse.

Buddleias, increasing (T. Grace).—The best way is to take cuttings of the young wood with a heel attached, and insert them either in boxes, pans, or pots, and then in the following spring plant them outdoors in lines 2 feet apart, where they will make rapid growth. The following autumn cut them back to two or three eyes and plant them in their permanent position, which must be a sheltered one. The soil should be prepared for them, and if at all heavy plenty of leaf-soil added.

Spot on Rose leaves (Clare).—This is known as the Rose leaf black blotch. It is a very common fungus, and many growers treat it as of small account, except that it disfigures the plants. If you spray your plants next year with copper solution, you will be able to keep it in check. Gather up all the fallen leaves and burn them. The recipe for making the copper solution is as follows:—Carbonate of copper, 1 oz.; carbonate of ammonia, 5 oz. Mix these together in a quart of hot water, and then add 16 gallons of water. Apply at intervals of a few days until you are satisfied that the fungus has been checked.

Propagating Clematises (Link).—The Clematis does not readily strike from cuttings, the only way to increase it in this way being from the young shoots in early spring. The cuttings, however, need a good deal of care and attention. If a few shoots are conveniently situated you may layer them either in the border (if the plant is growing in one) or in a few pots placed conveniently for the purpose. The stem should be partially cut through near a joint, and the knife brought upward for an inch or so, exactly as the layer of a Carnation. It should be fixed at such a depth that the cut portion is a couple of inches below the surface of the soil, which must be kept at all times moderately moist.

VEGETABLES.

Mildew on Cucumber leaves (Herbert E. Price).—Sulphur, of course, is the best remedy for mildew, but in the case of the leaves sent, nothing you can do will be of any avail, and we should advise you to throw the plants on the fire-heap and have the house thoroughly cleaned. In all our experience we have never seen leaves so badly mildewed.

Lettuce plants starting to flower (R. H.).—It is not at all unusual for Lettuce plants to start off to flower rather than to heart in, but it usually arises from either sowing seeds so thickly that they become weak and drawn rather than stout and sturdy, or because of hot, dry weather and soil affecting them, or because the seed stocks were bad. We cannot, of course, tell which of these causes may have operated in your case, but we advise you to sow at once, and very thinly. Get the young plants dibbled out early, and keep them growing on without check, watering them freely in dry weather. Lettuces like highly enriched soil, as being essentially leaf producers, the more rapid the growth the better they are for eating.

MISCELLANEOUS.

Preparing ground for lawn (H. B. Spinks).—The first thing to do is to see that the ground is thoroughly well drained. Then, having made sure of this, have the ground well manured and trenched, burying at the same time all the rough Grass, surface weeds, and soil. Then let it lie for a time to settle. When this has been done it should be made very firm and level. Seeing you do not wish to use turf, your best plan will be to procure some good Grass seed—not that from a hayloft, which is full of weed seeds—and sow the lawn down.

SHORT REPLIES.

M. G. D.—Your best plan will be to get a copy of "The English Flower Garden," from this office, price 15s. 6d. post free, in which the whole question of hardy flower borders is dealt with and illustrations of the same given. —**R. F. H.**—Kindly send some of the Cyclamen corms you refer to, with some information as to their age and mode of culture. —**A. M. M.**—Impossible to say what is the cause of the failure, as you give us no idea as to how you have grown the plants. —**M. E. K.**—On no account use the sawdust manure for making up a Mushroom bed, as this will only breed fungi and ruin the Mushrooms. Far better try making the bed with leaves only. —**W. M. Crowfoot.**—1, Yes, it will be advisable to give the plant greenhouse treatment. In the west of England it would probably thrive in the open if given a warm wall. 2, Your best plan will be to forward a specimen to Kew; they may be able to help you. We cannot find such a name as you give.

NAMES OF PLANTS AND FRUITS.

Names of plants.—**A. P. Farnham.**—The Thorn Apple (*Datura Stramonium*), a common roadside weed in southern Europe and all over the warmer parts of the globe. Found in the south of England, but can scarcely be considered as naturalised. —**Z. R.**—The common Golden Rod (*Solidago Virga-aurea*). —**W. S. S.**—1, *Abutilon vexillarum*; 2, *Justicia carnea*; 3, *Tradescantia zebrina*; 4, *Diplasia glutinosa*. —**F. R.**—1, *Saponaria officinalis* fl.-pl.; 2, *Centaurea suaveolens*; 3, *Thymus Serpyllum*; 4, *Polygonum cuspidatum*. —**C.**—1, *Calceolaria violacea*; 2, *Helenium pumilum*; 3, *Chelone barbata*; 4, *Campanula muralis*. —**Inquirer.**—1, *Senecio pulcher*; 2, *Francoa ramosa*; 3, *Hieracium aurantiacum*; 4, *Achillea ptarmica* The Pearl. —**B. W. J.**—1, *Hibiscus syriacus* var.; 2, *Sedum spectabile*; 3, *Malva moschata alba*; 4, *Chicory (Cichorium Intybus)*. —**H. D.**—1, *Aster Amellus*; 2, *Aster acris*; 3, *Euphorbia Lathyris*; 4, *Tradescantia virginiana*. —**R. C. B.**—1, *Veronica Andersoni*; 2, *Erigeron speciosus*; 3, *Hemerocallis fulva*; 4, *Nepeta Mussini*. —**H. C. Innes.**—*Leycesteria formosa*. —**Mrs. B. M. Durnford.**—Impossible to name from such specimens as you send us. —**Emily D. Prichard.**—Impossible to name without flowers.

Names of fruits.—**A. G.**—Apple Cellini.—**V.**—Apples: 1, Beauty of Bath; 2, Jacob's Seedling; 3, Early Julien; 4, Lord Suffield.—**E. N. J.**—Apples: 1, Kerry Pippin; 2, Mank's Codlin; 3, Margaret; 4, Duchess of Oldenburg.—**J. R. B.**—Apples: 1, Devonshire Quarrenden; 2, Irish Peach; 3, Stirling Castle; 4, Pear Williams' Bon Chrétien.—**J. C. B.**—Apple Worcester Pearmain.—**A. Y. L.**—Pear Beurré Superfin.

CATALOGUES RECEIVED.

E. P. DIXON AND SONS, LTD., Hull.—Catalogue of British Garden Bulbs and Nursery Stock.

G. W. MILLER, Clarkson Nurseries, Wisbech.—List of Alpine and Herbaceous Plants.

PHILIP LE CORNT, Queen's-road, Jersey.—List of Fruit-trees; List of Roses.

PREMIER SEED CO., LTD., 117, London-road, Brighton.—British and French Grown Bulbs and Seeds, 1916.

The National Sweet Pea Society proposes to hold the Novelty Trials of Sweet Peas as usual in 1917. The seeds for trial must be in the hands of the secretary not later than September 30th, 1916. For further particulars apply to the secretary, Mr. Henry D. Tigwell, Greenford, Middlesex.

OBITUARY.

MR. EDWARD MAWLEY.

WE regret to announce the death, on Friday, September 15th, at the age of 75, of Mr. Edward Mawley, who for thirty-seven years was the honorary secretary of the National Rose Society. On his resignation in 1914 he was elected president, which position he occupied at the time of his death. At one time, too, he was a prominent exhibitor and raiser of Dahlias. He was a member of the Floral Committee of the Royal Horticultural Society, and his opinion on any new Rose submitted to that body was always welcomed. He was also one of the recipients of the Victoria Medal of Honour. Mr. Mawley also devoted a great part of his time to meteorology, and his notes on the weather used to appear regularly in the gardening papers. The Rose, however, claimed most of his attention, and to him in great measure is due the success of the National Rose Society.

Parcels sent to our office insufficiently stamped will, in future, be refused.

Bulb growers will oblige by sending early copies of their Lists and Catalogues to MANAGER, "Gardening Illustrated," 63, Lincoln's Inn Fields, London, W.C.

Guaranteed British Bulbs.

Free carriage and packing will be given to all orders of 10s. value when cash is sent with order. Smaller orders should have 6d. extra enclosed.

Daffodils.
Emperor, deep yellow, 9d. doz., 5s. 6d. 100.
Horsfield, white and gold, 7d. doz., 4s. 100.
Princes, primrose, 5d. doz., 2s. 6d. 100.
Sir Watkin, gold, orange, 9d. doz., 5s. 6d. 100.

Narcissi.
Barri conspicuus, orange, 4d. doz., 2s. 6d. 100.
Ornatus, white, 4d. doz., 2s. 100.
Giant Poet's Narcissus, white, 8d. doz., 5s. 100.
Pheasant's-eye, 4d. doz., 2s. 6d. 100.

Double Narcissus and Daffodils.
Double Yellow Daffodil, 9d. doz., 5s. 6d. 100.
Double Golden Phoenix, 8d. doz., 5s. 100.
Double Orange Phoenix, 8d. doz., 5s. 100.
Double White Narcissus, 6d. doz., 3s. 100.
Mixed Daffodils and Narcissi, 1s. 6d. 100.

Tulips.
Clara Butt, pink, 7d. doz., 4s. 6d. 100.
Golden Crown, yellow, scarlet, 6d. doz., 3s. 6d. 100.
Gesneriana major, scarlet, 8d. doz., 5s. 100.
Picotee, white, edged rose, 8d. doz., 5s. 100.
Macropolis, crimson, 6d. doz., 3s. 6d. 100.

Large white Freesias, 8d. doz., 5s. 100.
Bluebells (Scillas), 6d. doz., 3s. 100.
Snowdrops, 6d. doz., 3s. 100.
Anemone St. Bridg., 8d. doz., 5s. 100.
Large Red Shallots, British grown, 4 lbs., 2s. 6d. 9 lbs., 5s.; 14 lbs., 7s. 6d., carriage paid.

"A B C" of Bulb Culture, two penny stamps.
Send your order to-day, or write for catalogue.

THE STEMS OF THE PINE.

THIS season I have seen more country places and gardens than usual of recent years, and everywhere I see the ugly result of not considering the natural way of the Pine. Master and man may be heard deploring the health of trees that are merely following the natural way of throwing off the lower branches as a summer-leaving tree throws off its leaves in the fall. The columnar stem one may see in both natural and planted forests, the stems of many trees often quite bare, all the branches having been thrown off as a deer throws off its horns, leaving the top free to fight its way in the air. It is getting the nursery form of the Conifer into their heads that leads so many astray. True the young Pine tree in a wild state has a bushy start, but loses this as it grows up, whereas in our pleasure grounds a tree is wept over if it shows a sign of taking on its natural habit.

I fear I was under the same delusion that Conifers should be dressed in green crinolines before I woke one morning in the train crossing the Rocky Mountains and saw all round me stems of magnificent Pines, but no signs of the tops! The same fact may be noticed in the natural forests in France and Italy, where one can see these Pines with straight stems as free of branches as gun barrels. The first time I ever saw a Cedar with a tall stem was in a wood at Shrubland Park. Very seldom have I seen groups of such a noble tree as the Lebanon Cedar except once at Redleaf.

There is something in our mild climate which encourages the false growths from the trees, but in their native woods it is different, and one seldom sees anything of the kind in the woods of California. On the east side of the mountains, when we see the yellow Pine (*P. ponderosa*), we notice that it grows alone, still without its lower branches, having healthy plumes at the top. In pleasure grounds, where the trees are generally planted singly, the plan is against the natural form, and the absence of grouping in such cases is disastrous. There is evidence on all sides, both in large and small places, that a wrong way is followed.

Even at Kew many of the finest old Conifers there lose half their beauty by straggling branches coming down too near the ground. A tree so dressed all down is much more exposed to the danger of wind storms than one growing with much of its stem bare.

I have lately seen a little grove of the yellow Pine with fine healthy tops, but all the lower part sickly, and I appealed to the owner to take off the dead and half-dead lower branches and make the trees look better and healthier. Half the beauty of a Pinetum is lost by the worn-out and often useless branches being kept on long years after they had done their work.

The noble grace of form of many trees of the Pine tribe, such as the Nootka Sound Cypress, is often hidden by a half-useless mass of branches near the ground.

In many places much of the beauty of our noblest native evergreen, the Yew, is lost by old, worn-out branches hiding the finely-coloured stems. Removing these lessens danger in the storm and adds to the beauty of the scene.

Pine views to and from the house are often shut out from the mass of shoots of Pines near the ground. Removing these alone may open up good views. In the case of established trees no harm can arise from clearing the stems for 15 feet or so. A handy woodman does the work best.

In woods close planted, as all Pine woods should be, the trees get rid of their lower branches, and should be allowed to do so. It is a waste of labour to aid them in the task. Whether the fall of the branches is the work of the tree itself or that of the woodman, the question may arise what to do with the refuse, some taking the trouble to burn or otherwise get rid of it. On no account should that be done, but the whole allowed to decay on the ground, and help in forming a surface of leaf-mould. As Pine woods are often planted on thin or poor soils they will benefit by the decay of the branches and all brush.

W.

NOTES OF THE WEEK.

Solanum crispum.—I have had this for ten years doing well, and flowering annually and profusely on a north-west wall, where it never sees anything but the last rays of the setting sun. It is now 20 feet high. It should be spurred back to the old wood like a Vine in the spring.—L. H., *Nuneham Park, Oxford.*

Ononis rotundifolia.—The round-leaved Rest Harrow, mentioned on page 436, is, unfortunately, not too hardy, especially when the plants grow large. It frequently survives for a few years and then is killed in some severe winter. Happily, seedlings are easily raised, and self-sown ones fre-

quently appear. It likes a dryish position and plenty of sun. The large pink flowers are very beautiful against the pleasing foliage.—S. A.

Lilium speciosum Melpomene.—This is not only the most richly-coloured form of the whole of the speciosum group of Lilies, but one of the handsomest in the genus. Where a bold striking effect is desired in the garden or conservatory this Lily will prove invaluable. The flowers are of an intense blood-crimson, and, being large and freely produced, render it a striking object. Being of a vigorous constitution and perfectly hardy, it should be freely grown for autumn effect.

The Blue Rock Bindweed (*Couvolvulus uauritanicus*).—This is invaluable for the autumn rock garden, and is now (beginning of September), and has been for weeks past, covered with its elegant blue flowers. I grow it high up in a retaining wall with a south aspect, and in warm, sandy soil, where it is quite hardy and improves each year. It is supposed to be a little tender, but in a warm, dry position it will come through any ordinary winter. It is easily raised from seed.—N. L.

Rose Zephirin.—I have plants of this within view of my cottage window, on their own roots, growing and blooming well, the fine rose colour, with a tinge of orange it seems to have in it as the early sun strikes it in September, showing up well. I shorten the name to a single word, the right way for all Roses. Its growth from September cuttings is free and graceful. I have no reason to doubt its growing well on the Dog Briar, but if I had a light, dry soil I would only look for a good result with own-root plants. It has more than one name. I adopt the above as the best.—R. H. S.

Antirrhinums in the flower garden.—Recently, looking at the display of bloom at several stations on the Glasgow and South-Western Railway, I was struck by the freedom with which Antirrhinums have been used. At almost every station these have been planted in good masses, the display, on the whole, being most effective. The only point in which an improvement might be suggested is that more decided colours could very well be used, there being too many pale pinks and mediocre yellows. Speaking to one of the station-masters on the subject, he appeared to regret that he had not used Zonal Pelargoniums instead of Antirrhinums, but in such a wet season as this has been the latter must have been much more satis-

factory. The blooms of Pelargoniums soon succumb to damp, whereas those of Antirrhinums do not so readily affected by prolonged wet.—W. McG., *Balmæ*.

Erica vagans St. Keverne.—The new variety of *Erica vagans*, called St. Keverne, is an acquisition to the autumn-flowering Heaths. At this time of the year alpine flowers are generally scarce, and the Heaths, charming in themselves, are doubly useful. We owe St. Keverne to Mr. P. D. Williams, of Lanarth, and a charming variety it is. The colour is a clear pink, as nearly as one may describe it, the blooms being in neat heads.—S. ARNOTT.

Grouping plants.—Some of the finest effects in gardens are got in the simplest way. This is especially true in small gardens, where one thing only is grown, when it suits the soil, and so is grown well. Even in large gardens and parks the best effects are those gained by planting a mass of a good thing, such as Narcissi or Tulips, Pansies or Polyanthus, all of one kind, in bed or in border, or in groups on the Grass, as the case may be. To group different kinds of flowers together requires a good deal of artistic knowledge, and taking our parks and gardens generally we are quite as often offended as we are pleased with mixed planting. On the other hand, we are seldom offended by beds, borders, or masses of one plant if it be well grown.

Changing recognised botanical names.—It is a heavy task to commit so many names to memory, but it is far more difficult to unlearn what one has already learnt, and substitute other names for those that are so well known. I met with a case in point in the "Kew Hand-List of Tender Monocotyledons," which was published last year. The genus *Dracæna* has been long recognised in gardens, indeed the members of the allied genus, *Cordylina*, used to be referred to as *Dracænas*. With these eliminated there still remained a goodly list of what might be regarded as true *Dracænas*, but reference to the above list showed that, with the exception of *Dracæna Draco* and two or three doubtful species, the whole of them are now placed in the genus *Pleomele*. Thus such well-known kinds as *Dracæna fragrans*, *D. Godseffiana*, *D. Goldiana*, *D. Hookeriana*, *D. Sanderiana*, *D. sureulosa*, and others all disappear from that genus and crop up as *Pleomeles*. This chopping and changing of names lead one to ask the object of it all, unless it be the desire on the part of some recognised botanist to pose as the authority for a new name, which is, however, not likely to be generally recognised. K. R. W.

Viburnum lobophyllum.—Amongst the many new shrubs introduced from China during the present century are numerous species of *Viburnum*, some of which are of interest by reason of their evergreen leaves, others on account of attractive flowers, and others again by the showy character of their fruit. *V. lobophyllum* belongs to the last set and is, perhaps, the most effective species of all in autumn. It is a vigorous, rather loose-branched bush at least 8 feet or 10 feet high, with strong branches clothed with broadly-oval or rounded leaves. In May or early June large flat heads of white flowers are produced, these being followed by numerous fruits, which, when ripe in September, are of a rich, bright red hue. Like the majority of the stronger-growing *Viburnums* it succeeds in almost any kind of good garden soil and soon attains flowering size. For a sunny place in a shrubbery it is well adapted, whilst it would also make an excellent bush for planting in large groups in semi-wild positions. There are various other *Viburnums* that

are excellent fruiting plants, and it is only necessary to direct attention to the common *V. Opulus* in both its yellow and red-fruited forms and to *V. Lantana*, with its red and black fruits, to show what attractive fruiting shrubs the genus contains.—D.

Sweet Peas.—We welcome the improvements that have been made in Sweet Peas in recent years, but the naming is overdone. It tends to confusion and distracts attention from the sorts that have been well proved and are really good and distinct. Taking up a few seed catalogues there would not be the least difficulty in compiling a list of thirty or forty named varieties, all of which are claimed to be distinct, but which, when grown, are found to be very much alike. Anyone who has the space and the time may test this by growing a collection. A few good things may be discovered and also many that should never have been named at all. We are greatly indebted to those who have spent so much labour among Sweet Peas, but it is to the interest of all concerned that those sent out as new should be distinct, and only when this is the case can the interest and the popularity of the flower be extended and sustained.

Pentstemon heterophyllus.—"W.," in concluding a note on this unique species at Friar Park which, near the finish of its flowering, I had the privilege of seeing, says "it is well worth raising from seed." If the seed could always be depended upon there would be no doubt about it. Often, however, the mixtures one gets for it are of such a nature and the nondescript colour so inferior to that of the typical kind that only with knowledge of the way seeds were harvested would I recommend such a course. Only a few days since I pulled up a bed of it, in which a dozen pieces were as weedy and inferior, both in foliage and flower, as could be imagined. The true plant is so beautiful that it is worth a little care to retain, and a few cuttings inserted each year will do what is necessary to this end. By early removing a few of the flower-spikes cuttings of the right stamp will be forthcoming, and, when quite young and about 2 inches long, root quite freely with cold-frame treatment. Seeds saved from such a group as that referred to should, however, be reliable.—E. H. J.

Veronics in pots.—Those who saw the fine collection of these exhibited by Messrs. H. B. May and Sons at the Royal Horticultural Society's meeting on September 12 must have been impressed with their beauty when grown in pots. They, in 5-inch, 6-inch, and 7-inch pots, varied from 1 foot to 2 feet high, and as much across. These had foliage down to the pots, with many shoots literally covered with flowers. When grown in this way, few things are more useful for house furnishing, and far more enduring than many things grown in warm-houses. Such plants as shown can be obtained in this nice dwarf state by rooting the cuttings in autumn, keeping them in cold pits till spring, and then potting singly into 4-inch pots. When the pots are full of roots, repot into the blooming pots, plunging them all the summer in an open place, and pinching in the early stages to make them bushy. When full of roots, give manure-water frequently. These *Veronics* are excellent for the open garden in western districts, and are often seen in large bushes blooming the greater portion of the winter. The following are a few of the best sorts:—Attraction (rich violet), Diamant (fine crimson), Mont Blanc (the best white), Reine des Blanches (blush-white), La Perle (reddish-carmine), and Lavinia (royal purple).

VEGETABLES.

STORING POTATOES.

Those who have ample room in frost-proof cellars or sheds can do nothing better than transfer the tubers to these at once, taking care that they are not placed in heaps sufficiently big to set up heating, and also that they are not bruised by rough treatment in transit, this being especially necessary with tubers that have to be kept for many months. Provided the cellars or sheds are not cool, I strongly advise

CLAMPING in preference to such storage, which would be productive of evil in more than one form. Clamping is so simple that it would seem almost impossible to make a mistake in it. Still, mistakes are sometimes made, and the worst form of clamp is that in which a large square pit is dug for the reception of the tubers, as in such a place a large bulk of tubers would be certain to become overheated, while in wet weather they would get swamped. The better way is to select a cool, shaded, and well-drained position, and to mark out a portion of ground some 3 feet or 4 feet in width, and long enough to hold the bulk of the tubers when heaped on it in ridge fashion, making the ridge as high as possible without running beyond the allotted width at the base. When all are in position a thickness of from 6 inches to 12 inches of dry Bracken should cover the heap, and on this again some 6 inches of soil dug out from around the heap, thus forming a trench, which will keep the clamp high and dry. It is well not to be too sparing of the Bracken, or any substitute which may be used, as a good coating of this will keep out frost in the severest of winters. I prefer making one long clamp for the eating size rather than several smaller ones, as each variety can be separated from its neighbour by a division of Bracken, and they may be so arranged as to come in proper rotation for use, so that the clamp need only be opened at one end when tubers are wanted. By making the clamps no wider than I have recommended I find that the use of drain-pipes or any other method of admitting air at intervals along the heap may be dispensed with, no air being required to prevent overheating.

SEED POTATOES.—These should be selected at lifting time and placed by themselves at one end of the clamp, taking care to prevent them from getting mixed. I do not care for large seed potatoes. The present is by far the best time to buy in stock or to make exchanges of seed. Those who leave this important matter until the usual time for ordering other garden seeds will probably have them come to hand with many of their best shoots rubbed off, besides running the risk of their being frozen on the journey. At this time of the year there are no shoots to damage, and there is but little fear of any injury. T.

NOTES AND REPLIES.

Manuring kitchen garden.—I want to cultivate half an acre of garden without using animal manure. Please tell me how to proceed? Quite half the garden is still occupied with Beans, Artichokes, Beet-root, Cabbage, Broccoli, Brussels Sprouts, Salsafy, with Spinach and Lettuce just sown. Must I now sow all the vacant plots with Mustard seed and dig in the plants in March, or must I dig the vacant ground now roughly for the winter and sow Mustard in February, digging it in later when I want to sow the usual spring seeds? Is this method of manuring as satisfactory as using farmyard manure or artificials?—WOMAN GARDENER, Co. Durham.

[You can hardly look for the garden in

question to yield satisfactory crops year after year without returning to the soil something more than an annual crop of Mustard with which to maintain its fertility. The digging in of Mustard now and again would answer very well, but, if continued without a change, the soil will soon become Mustard "sick," which condition would soon be reflected in the unsatisfactory condition of the crops grown. Farmyard manure is the best fertilising agent for garden crops in general. Artificial manures can be used in lieu of it for a few seasons, but there comes a time even then when it is imperative to apply something of a more substantial nature; to wit, farmyard manure. Where the latter is usually employed for the garden it is a good plan to substitute now and again a good dressing of lime for it. This answers the same purpose as manure and sweetens the soil. Although rarely practised in gardens, the growing and digging in of a crop of Mustard would often prove beneficial, but

of this usually reliable vegetable is to be regretted, and I can only attribute it to the phenomenal weather which prevailed after planting time. It would be interesting to learn if Cauliflowers have behaved similarly in other districts.—W. McG., *Balmac, Kirkcudbright.*

TREES AND SHRUBS.

ESCALLONIAS.

THE Escallonias form an exceedingly ornamental class of flowering shrubs, natives for the most part of Chili and adjacent regions. Nearly the whole of them are evergreen, and their season of blooming extends over a lengthened period, from midsummer onwards. They are too tender for general cultivation in the open ground throughout the greater part of the country—indeed, to see them at their best one has to visit the extreme south and south-west of England, while

white, with a pinkish tinge, and a succession is kept up from July till autumn is well advanced. It is one of the hardiest of the evergreen kinds, and a free-growing shrub of graceful habit.

E. LANGLEYENSIS.—This is a cross between *E. macrantha* and *E. Philippiana*. The small, dark, shining green leaves show a good deal of the influence of *E. Philippiana*, while the flowers, which are borne in quantity, are of a pretty rosy-pink shade.

E. MACRANTHA.—One of the finest and most generally grown of all the Escallonias, being sometimes met with under the names of *E. Ingrami* and *E. rubra Ingrami*. It forms a large, bold-growing shrub, clothed with handsome, shining, dark-green leaves, so that even when out of bloom it is decidedly ornamental. The flowers, which are borne in terminal racemose clusters, are bright crimson in colour, and consequently make a goodly show. Under favourable conditions it will flower from July till stopped by the autumnal frosts. Its recuperative powers are so great that in many cases, even if severely cut by the winter, it quickly recovers. As a wall shrub it is a general favourite in many parts of England, as with this amount of protection it will stand most winters. We also know of some plants of this growing and flowering freely against a wall as far north as Aberdeen.

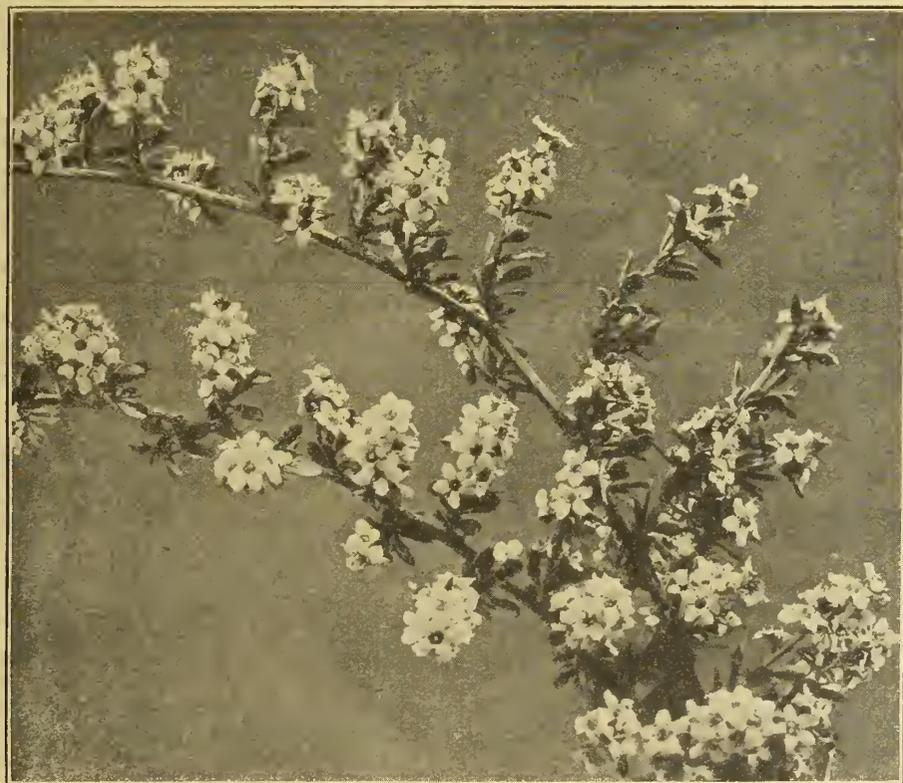

E. MONTEVIDENSIS.—By some authorities *E. floribunda* is considered to be the correct name of this, while by others the two are kept distinct. At all events, it is generally known as *E. montevidensis*. This is one of the most tender of the entire genus. It is a rather upright, bold-growing shrub, whose large terminal clusters of pure white flowers are borne during the latter part of the summer and well on into the autumn. In the favoured districts of Devon and Cornwall it is very handsome.

E. PHILIPPIANA.—This, a flowering shoot of which we figure to-day, is the hardiest of all, and differs markedly from the last in being almost, if not quite, deciduous. It forms a rather spreading shrub, whose long, arching branches are disposed in a very graceful fashion. The leaves are small and dark green in colour and serve admirably as a setting for the pretty star-shaped white blossoms, which are borne for a considerable distance along the shoots. From midsummer till well on into July it is one of the most charming of outdoor flowering shrubs. In the London district this is never injured by frost.

NOTES AND REPLIES.

The Sun Rose (*Helianthemum vulgare*).—This formed a feature of many gardens which I visited during my stay at Oxford in mid-June, and was used with wonderful effect as an edging plant to the herbaceous borders in St. John's College Garden, also as a rock plant in the same garden. The plants revel in the hot sandy soil which abounds in many districts near Oxford, and were a mass of bloom when I saw them. There are numerous double and single varieties and a magnificent range of colour.—E. T. ELLIS, *Wcctwood, Eccle-sall, Sheffield.*

The Tamarisk and Fuchsias.—There is a hedge in a village in south Hants formed of these two kinds of plants, and very beautiful it is. Attention may be drawn to the fact that the soil and position are very dry. Not far away we find the Tamarisk growing in a moist medium quite close to the tidal waters—in fact, in the spring the water frequently covers the roots and portions of the plants. Quite exposed to the sea breezes, Fuchsias this year growing and flowering more freely than in previous years, and neither flowers nor foliage seem to be seared in the least by this exposure.—G. G. B.

Flowering branches of Escallonia Philippiana. From a photograph at Hillbrook Place.

no gardener would dream of repeating it year after year with the idea of maintaining the soil in a high state of fertility. Half an acre of ground would not require such a great quantity of manure, and if you cannot obtain or afford to apply it annually, perhaps you could every other year. Mustard could then be used in the way you mention in alternate seasons, and lime once every five years.]

Cauliflowers.—Never in my experience have midseason Cauliflowers done so badly as during the present season. Planted out at the usual time, for a time the growth of the plants was all that could be desired. The inclement weather experienced during late June and early July appeared to act adversely upon them, and an inspection revealed that the hearts of the plants had, in many instances, perished. Of course, there was no suspicion of "blind" plants having been put out, nor is there any clubbing in these gardens; while no grubs or other pests are visible. The shortage

they thrive particularly well in many parts of Ireland. As with the majority of these South American shrubs, a humid atmosphere is favourable to their well doing, and they all flourish in proximity to the sea. Although, as above stated, they can be but little depended upon as open-air shrubs, except in the milder parts, they may be grown much farther north when trained to a wall, and in this way some of the species are very ornamental. They can be readily propagated by cuttings of the half-ripened shoots, taken in August and dibbled into sandy soil in a close frame. A well-drained, rather light sandy loam is the best for them, as in damp soils they are more liable to injury during the winter. A selection of the best and hardiest of the Escallonias would include the following:—

ESCALLONIA EXONIENSIS.—A hybrid, presumably between the deciduous *E. Philippiana* and one of the evergreen species. It is quite evergreen in character. The flowers, borne in terminal spikes, are

FRUIT.

WINTER SUBSTITUTES FOR APPLES.

I SHOULD strongly advise all growers to bottle as much of the small fruit in variety as they are likely to require through the winter, as there seems every probability of a very short Apple crop. Also, if opportunity offers, to pick Blackberries, which may be included, especially if they can be obtained from hedgerows away from the main road, where the berries are free from dust and the plants are growing in good, fairly heavy soil. Under such circumstances the fruit of the hedgerow will hold its own with the majority of the small cultivated fruits, and is in every way superior to that from a poor, light soil. Plums will also be available for a similar purpose—that is, in districts where they can be spared. It would seem from several notes that have appeared that the crop is not very plentiful. Here, however, in mid-Bucks, it may be described as a fair average, if in places a trifle under. For bottling, I prefer the small, rather round fruits of the type of the old Greengage, Early Prolific, and Reine Claude Violette. They should be good, sound fruit, and very nearly ripe. It is a mistake to suppose that indifferent fruit will come out satisfactorily, and if not fairly well advanced in the sugary stage before going into the bottles there will be a suspicion of bitterness that is decidedly objectionable.

The above provisions in the way of bottling spare fruit are the more advisable this year because, as above noted, there seems in the majority of districts a very short Apple crop, and consequently hardly any of that useful fruit available through the winter. This failure is somewhat unaccountable, because, at any rate so far as this neighbourhood was concerned, there was certainly not sufficient frost to injure the blossom at the time of its expansion, and as this was abundant the failure is more perplexing, and doubly so because wood and buds seemed to ripen satisfactorily in the summer and autumn of 1915. There was evidently some un congenial atmospheric influence at work that was not apparent during the flowering time. I find there is a light crop on some of the early kinds, but very few mid-season and late. This district is rather celebrated for its Blenheim, and in some seasons these provide the main supply for about three months of the year, but at the present time many large trees have scarcely an Apple. The best crop of late Apples I have seen is on some espalier Lane's Prince Albert, but apart from this the failure is apparent on all forms of trees, whether standard, bush, pyramid, espalier, or cordon.

Since writing the above I have read the article on page 384 of GARDENING ILLUSTRATED dealing with "Fruit Bottling for Small Holders." This is very interesting and explains the whole business from this point of view in a clear and concise manner, and is, I dare say, about the best mode of procedure for those who can afford the initial outlay. It strikes one, however, that an outfit that is to cost close on three pounds is more than the average cottager can afford, and, fortunately, the work can be carried out satisfactorily in a much less expensive manner. Place ordinary wide-mouthed sweet bottles filled with fruit in the oven, and after the fruit has been thoroughly warmed through without cracking fill the bottles with water that has been brought

nearly to the boil. Put on the stoppers and cover top of bottles with a starch plaster. The fruit will keep sound and good in this way for a couple of years.

Hardwick.

E. B. S.

NOTES AND REPLIES.

Treatment of Raspberries.—I planted a lot of autumn Raspberries (red) last Christmas. There are now either one or two fruiting-canes on each; in addition, a number of young canes without fruit have come up on each. Should these be left or should they be cut down in February? If left, would they bear next year?—AURELIUS, Co. Cork.

[The weakest of the non-fruiting canes should have been cut out as soon as it was seen they would be of no service. The others would have done more good than harm by allowing them to remain, as they encourage root-action and assist in the stools becoming firmly established. Cut all down close to the ground next February or March, and when new canes push up leave a sufficient number of the strongest, so that they will stand 9 inches apart when tied to the wires, cutting the remainder clean out. The canes in question would, if left, be of no service next year.]

Raspberries, autumn-fruiting.—How ought autumn-fruiting Raspberries to be treated to ensure their fruiting in time for the fruit to get ripe before the weather gets too cold? Mine did well the first year, but since then the fruit has not formed till so late that it never ripens.—K. M. B.

[The treatment of the autumn-fruiting kinds is quite different from that given to the summer fruiters. In the case of the autumn-fruiting kinds the canes should be cut close down to the ground in February or early in March, as it is on the young canes made in the current year that the fruit is borne. When growth commences, the canes should be well thinned and all superfluous growths cut away.]

Plums.—The weather of late has been the worst possible for the keeping of Plums after they are ripe, this being more apparent in the case of trees in the open than with those on walls. In the former case there is no help for it but to gather the fruit when it commences to split and utilise it for whatever purpose may be deemed best under the circumstances. On walls, especially where good copings exist, or where glazed copings are fixed, this difficulty has not to be contended with, as the fruit, both that which is ripe and ripening, is not so subjected to the baneful influence of rain and moisture. It is always a good plan when heavy crops set on trees of valuable late varieties, such as Coe's Golden Drop, Jefferson, Ickworth Imperatrice, Pond's Seedling, River's Late Black, Monarch, President, Coe's Violette, and Coe's Late Red, to let the coping boards remain over the trees instead of removing them at the latter end of May in all cases where the fixed copings are not of sufficient width to shed the rain clear of the trees. To protect the fruit from the ravages of birds, wasps, and flies, muslin or hexagon netting is the best material to employ. For birds alone, ½-inch netting suffices.

Strawberries—stacking pot plants.—Much has been written from time to time for and against this method of protecting Strawberries in pots through the winter. Those who have had to protect many hundreds of plants know the amount of space they need. This method when rightly used commends itself to those with limited space. It is not the plants that need protection, but the pots and the roots. Last February, when calling on a grower I have known for many years, I observed he had several hundred plants stacked one above another against a low wall with ashes between them. I looked at them to see if they were moist, and found them not in the least dry, the rain having gone through the whole. My friend said he had tried many methods, and found nothing to equal this.—DORSET.

GARDEN PESTS AND FRIENDS.

BLACKBIRDS IN THE GARDEN.

At the time of writing, when the drought adds much to the worries of the gardener, the blackbirds are a serious menace to the fruit crops. They are always more or less in evidence and ever ready to attack unprotected small fruits of all kinds. Now these are about cleared their attention is turned to Plums, both wall and bush grown, even quite green fruits being attacked. I do not usually find them attack Plums in a green state, yet their habits vary with the seasons. Sometimes I have found them take yellow Plums and leave the purple fruits. In other seasons the opposite has happened. While one has to report so badly of the blackbird, its ally, the thrush, though also fond of soft fruits, has disappeared from the garden, presumably into the woods, where there are loose leaves it can disturb readily in search of food. Blackbirds, on the other hand, seem to congregate in the garden from the field and woodland. Apples and Pears come within their scope, and they have a singular liking for early maturing sorts. I have had to clear what few Beauty of Bath and Irish Peach Apples there were, or in a day or two all would have disappeared. The blackbird is no doubt a fine summer songster, but the garden has to pay a heavy toll. Its natural food seems to be mainly worms, and in the search for these in manure and leaf beds it is usually regarded as a nuisance both in summer and winter. It is only by netting that one can save any kind of garden fruit, and in the case of large areas or large trees this is, of course, impossible, and it would seem that no form of scare is effective. Blackbirds are too wary to be trapped, and shooting is out of the question, as they appear in such numbers about the garden. This bird problem is really a serious one where fruit crops are so limited. Some profess that birds are made welcome to their garden crops, but I cannot agree with this.

W. STRUGNELL.

NOTES AND REPLIES.

Strawberry foliage injured.—Would you kindly tell me what ails this Strawberry leaf and whether it is contagious or likely to infect other plants, and how to treat it?—A. J. MACKAY.

[The Strawberry is attacked by the Strawberry leaf spot (*Sphaerella fragariae*), which causes a kind of mildew on the foliage, etc., and altogether does a good deal of harm. Now is the time to deal with it, but the treatment should not be delayed. With a scythe or hook cut off all the foliage over the bed, allow it to dry, and then set fire to it on the bed. This (unless the plants have recently made much young growth) will do no harm whatever, and will rid you of the trouble better than any spraying treatment you can give now or at any time.]

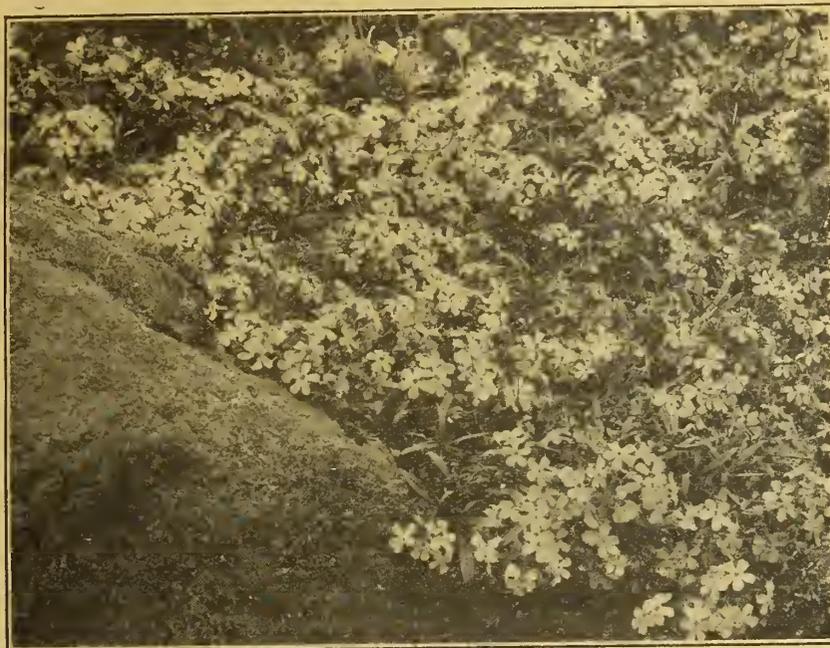

Injury to *Romneya Coulteri* (Mrs. Northey).—The caterpillar you send is either the Angleshades (*Phlogophora reticulosa*) or the common Turnip moth (*Mamestra brassicae*). It is not far enough developed to say yet, though we think it is the former, which is the common enemy of the *Romneya*. The best thing in any case, failing hand-picking, which is likely to be the most thorough remedy, is to spray the plant with lead arsenate, which you may buy in paste form of any horticultural sundriesman, and use according to the directions, beginning as soon as there is the least sign of attack, and repeating if necessary.

PLANTS AND FLOWERS.

ROCK, ALPINE, BOG, FERN, AND WATER GARDENS.

SAPONARIA BOISSIERI.

THE accompanying illustration gives a very clear idea of one of the most beauti-

Saponaria Boissieri at Friar Park.

ful and profuse of summer-flowering alpine, one whose wealth of rosy-pink blossoms suggests at sight a concentration in compact, almost tufted form of all that is best in a good *S. ocymoides*. The plant is a hybrid of garden origin and quite recent introduction, and I am not aware of its parentage. That, however, is of less import than the decorative value of a new-comer, and particularly of one so full of promise. Three inches or 4 inches high, it forms a spreading tuft of short-jointed, wiry stems from every leaf-axil of which the pretty 3/8-inch wide five-petaled flowers issue with the utmost profusion. By reason of its dwarfness it is essentially a plant for the rock garden, providing pretty effects during July and August, when the fuller wealth of choice subjects is on the wane. A sunny slope in gritty, well-drained loam suits it well, or it may be used with good effect crowning a rocky ledge.

E. H. JENKINS.

NOTES AND REPLIES.

Saxifraga oppositifolia.—The notes on this little alpine which appeared recently in GARDENING ILLUSTRATED are brimful of interest and are instructive, but I should like to have seen recorded the experience of some owners of Surrey gardens. I have seen plants in this district which were the picture of health. I have had them myself in the same condition, but the luxuriance did not bring with it free flowering. I fancy that there is something in the atmospheric conditions of some localities—it cannot be soil, as that is specially made to suit the various needs of alpine plants—which acts prejudicially on the formation of flower-buds. I will, however, act on the hints given by your correspondents, and hope I shall obtain what I have never had, that is, plants smothered with bloom. I have at various times bought this Saxifrage in and out of pots by the dozen,

sometimes in the blooming time, but although the plants were really good, there were very few blossoms on them. Not a single plant was in the condition described by Mr. Elliott.—BYFLEET.

Fuchsias in the rock garden.—The only two varieties of dwarf Fuchsias I have experimented with are *pumila* and *Tom Thumb*. Both are good, and when in full

flower make bright patches in the rock garden. With me *Tom Thumb* does not exceed 5 inches in height, while *pumila* is but a trifle taller. To make certain of their standing the winter they should either be taken up and potted, have a piece of glass placed over them, or the crowns be well covered with coarse sand. This prevents their rotting away, a danger to which small Fuchsias are very liable on heavy soils.—C. T.

AN INFORMAL BRIDGE.

IN order to obviate a formal bridge, irregular stones have been placed by

An informal bridge.

which to cross the little stream. The banks have been planted with *Primula rosea*, various small Grasses, Rushes, and other water-loving subjects. From Mrs. Greer's garden, Curragh Grange, Co. Kildare.

R. H. BEAMISH.

INDOOR PLANTS.

NOTES AND REPLIES.

Keeping Gloxinias.—How can I keep Gloxinia bulbs through the winter? I have kept them in dry litter indoors, and in dry earth in a damp greenhouse, but always lose 50 per cent. through what looks like rot.—J. S. T.

[Gradually diminish the water supply till the foliage dies down and the plants become quite dormant, when they should be kept dry. During the time the leaves are dying down let the plants have all the light possible. In the winter you may leave the corms in the pots or shake them out and lay them in boxes of dry sand. The temperature of the house in which the Gloxinia corms are kept during the winter should never fall below 45 degs. Repot early next March, being very careful as regards watering until you see that growth is on the move.]

Diplacus glutinosus.—Will you kindly let me know in your paper when to repot and soil to use for *Diplacus glutinosus*, just done flowering?—Geo. VICK.

[This will, in a greenhouse, flower throughout the summer months, while out-of-doors it is equally free-blooming. It should be given much the same treatment as a Fuchsia, for during the winter it needs protection from frost, and only just sufficient water to keep the soil slightly moist. Repotted in the spring in a mixture of loam and sand, with some rotten manure or leaf-soil, the young plants will grow away freely, and soon commence to flower. If given an occasional stimulant they will continue to bloom till the autumn. This *Diplacus* is readily increased by cuttings of the young growing shoots taken in spring and placed in a close propagating case. Good-sized specimens may often be seen planted out in the mixed flower beds, which are during the summer so much in vogue in many places. While the flowers of the typical *Diplacus glutinosus* are of a kind of buff tint, there are varieties known as *coccineus* and *Sunbeam* with flowers of a richer colour. When fully exposed to the sun the tint of these last two is particularly bright. *Diplacus glutinosus* is a native of California, and though hardy in especially favoured districts, it must in most parts of this country be regarded as a greenhouse plant.]

Trichinium Manglesi.—This is now very rarely seen outside of a botanic garden.

In its inflorescence it is very distinct. From the tuft of small narrow leaves, which lie almost flat on the soil, the flower-heads are pushed up. They are supported by thin, wiry stems, each from 6 inches to 8 inches long, but not suf-

ficiently strong to hold the cluster in an erect position. These clusters form an oval-shaped head, like a ball of fluffy cotton, from which the pretty pink petals protrude. These flower-heads retain their beauty for a considerable time. Some years ago I saw a specimen at Kew in a 5-inch pot with no less than 24 flower-heads. It is a native of sandy districts in Australia, and in this country needs a soil composed mainly of loam and sand with a little leaf-mould or thoroughly decayed cow-manure. Repotting should be done as soon as possible after the flowers are past. It can be propagated by root cuttings.—K. R. W.

Watering Chrysanthemums.—Just before the plants are housed the watering of Chrysanthemums occasionally takes up a good deal of time. More especially is this the case when, as often happens in mid-September, there is a period of bright, sunny weather, which may involve watering twice a day. At the present time, when labour is scarce, anything which may lessen this work ought to be considered. Plunging the pots, even if for only a few inches, conserves the moisture and makes the watering easier. If this cannot be done, considerable benefit may be found by placing spare boards in front of the rows of pots, this breaking the force of the rays of the sun. Spent hotbed manure packed among the pots is also serviceable. Any of the methods named is better than placing the pots under the shade of trees, for in such a position the wood cannot possibly ripen, and unripe wood will not produce good blooms—if, indeed, blooms are produced at all.—KIRK.

Cyclamens.—No further delay in sowing the seeds of Cyclamens is permissible. In sowing, let each seed be put in separately about, say, an inch apart. When time for transplanting arrives, seedlings grown in the manner recommended may be lifted without interference with the roots of each other. Plants which will be shortly in bloom may be lightly vaporised in order that stray thrips may be disposed of. If grown on a stage covered with gravel, crushed granite, or similar material, keep such material in a moist condition. I am no believer in shading Cyclamens at this period, as, if the plants have been grown coolly, the foliage will be sufficiently robust to endure the lessening rays of the sun with impunity. If stimulants be considered necessary, let them be of the weakest possible description. Indeed, where it is intended to save any of the corms for use during another season, I would prefer to withhold artificial aids, for it is certain that highly-fed corms will collapse when growth begins during the following season.—G.

Browallia speciosa.—I was pleased to see the note on this at page 450. I used to grow this largely for autumn decoration in the days before the Chrysanthemum was given so much attention. Needing a large lot of plants to keep a conservatory gay, and as the owner had no regard for Chrysanthemums, I used to sow seed of this Browallia in June, growing the plants on in the open till September. In my early days I used to grow this in a garden in Purbeck Isle, in the open, associated with *Schizostylis coccinea*. There being no frost till December, these kept on blooming till nearly that time.—J. CROOK.

Calanthe Veitchi and C. vestita are now finishing their growth, and in order to obtain strong flower-spikes and to secure clear, bright flowers the plants are placed near the roof-glass, giving every plant plenty of space, so that each may obtain its full share of sunlight. When the sun is very bright they require to be very thinly shaded during the middle of the day, to prevent scorching of the leaves. In the extra sunlight the plants dry up very quickly and require plenty of water at the roots. A little manure water may still be afforded them; but it must be discontinued after the flower-spikes have made some little progress.

GARDEN FOOD.

THE SWEET POTATO.

THERE comes to my mind a song which I used to hear "way down south in Dixie." It has to do with the statement that the greatest feast which "mammy" can put upon the board is incomplete without the sweet Potato! I can shut my eyes and go back to the old days—not "befo de wah," but to the days when we played about in the big kitchen porch and listened to the wonder tales of "old Aunt Lucy" as she hurried back and forth getting dinner. I can see the big checkered apron and the bandana kerchief round her head—and oh, the dinners! I can taste those delicious, baked sweet Potatoes yet!

The sweet Potato comes to us from the Malay Peninsula, and was known to Europeans before the white Potato—in fact, the latter takes this name from them—*batates*, the European corruption of the Eastern word. The white Potato soon supplanted the sweet in Europe, owing to the greater hardiness of the plant, and the sweet Potatoes became most popular where they could be grown with the best results; the semi-tropical sun gives extra sweetness to them, but the first touch of northern frost blights the crop. The difficulty in keeping the sweet Potato has also restricted its use, as it is not a good "keeper."

The greatest difference between the white and the sweet Potato lies in the carbo-hydrates, the latter containing a greater portion of sugar, part of which is cane sugar and part glucose. The starch varies according to climate—the food value of the tuber increasing in the warmer climates, and in the tropics the proportion of sugar and starch is almost equal. This large proportion of sugar is not so desirable, and the general market demand has led to the cultivation of those varieties which tend to store more starch.

The cooking of sweet Potatoes depends very greatly upon the variety. The dry starchy varieties must be boiled before they can be baked, while the sweet syrupy "yams"—as they are often *mis-called*—are delicious baked in the ashes or in the oven. Owing to the irregular shape of sweet Potatoes and the tough skin it is usually more convenient and less wasteful to cook them with their jackets on. Sweet Potatoes are wholesome, and are digested by the average person without difficulty. But while almost everybody eats the Irish Potato, there are many people who do not care for the sweet variety.—*Good Health*.

[The sweet Potato comes to our markets betimes, and, rightly treated, is a good winter food, but in our markets there is not so much choice as there is in American markets, and the quality is not always good.—ED.]

NOTES AND REPLIES.

Piccalilli.—I have a great many spare Cauliflowers this year. Can you give me a recipe for pickling same? Also for a good but inexpensive Piccalilli? I should be greatly obliged if you could. I have tried all ways, but cannot succeed in keeping them a good colour—they always turn black, both Onions and Cauliflower, and go rather soft.—OLD READER.

[Break the Cauliflowers into neat little flowerets, lay them in a dish (but do not wash them), and look them well over to be sure there are no insects. Get plenty of small, white-skinned Onions, French Beans, and Scarlet Runners, small Cucumbers, or large ones cut into nice thick pieces, Nasturtium seeds, a few Chillies, and some Cayenne pods, with a blade of Mace. On no account wash any of the vegetables. Have them gathered on a dry day, and wipe off any grit with a

dry cloth. Mix the vegetables and put them into glass bottles quite dry and clean. Put as much vinegar as you think you will want to quite cover the vegetables on to boil with a few Peppercorns, a few lumps of sugar, and a dozen cloves. Let this boil ten minutes, then mix $\frac{1}{2}$ lb. of flour of mustard with a little cold vinegar. Stir this into the boiling vinegar, let it just boil up, and pour it boiling over the vegetables in the bottles. Let stand until the next day covered close, then fill up the bottles with boiling vinegar. Tie down with well-cleansed bladder. If you prefer it you can omit the flour of mustard, using more Peppercorns. You can use as much Cauliflower as you like, but pickled alone it is very tasteless.]

Preserved Pears (Candied).—Secure some sound but scarcely-ripe Pears, plunge them into a stew-pan of boiling water for two minutes, cool them in cold water, and drain them. If small, peel each one neatly, and leave the stalk on; but if large, cut each one in half, and peel each one lengthwise, with only three cuts of the knife, if possible, putting them into bottles as they are peeled. Make a strong syrup, boiling 4 lb. of sugar with 1 pint of water until it is clear. Pour this over the Pears in the bottles, cork, and tie tightly down. Place the bottles in a pan of water, and boil for ten minutes; let cool in the water. Pears preserved in this manner will keep good for a long time.

A large puff-ball.—The fungus described by Mr. Phelps (p. 475) is the giant puff-ball (*Lycoperdon bovista*), and is the most delicious fungus known to me, provided it is cooked before the snowy-white interior assumes a yellowish tinge. The late Dr. M. C. Cooke, who devoted his life to the study of fungi, recommended that the giant puff-ball should be cut in slices a quarter of an inch thick, smeared with beaten egg, dusted with breadcrumbs, and fried in butter. It sometimes springs up in a bed in the kitchen garden, when it may be allowed to grow, slices being removed from it as they are required.—HERBERT MAXWELL, *Monreith*.

—Referring to the note, p. 475, these large puff-balls are by no means rare. I remember finding several as large as footballs in a Rhubarb bed in my garden in North London some years ago, and have several times come across them in the country. It is not generally known that they are edible; indeed, quite nice when young, cut into slices like bread and either fried with a little butter or toasted in front of the fire. I have many times eaten them for breakfast. There are several other edible fungi besides the ordinary Mushroom, but it needs some little expert knowledge to be sure of the species before experimenting. One such edible fungus, however, is easily recognised and is quite common in the country. It is known as the Parasol Mushroom (*Lepiota procera*). It has a long, slender stalk with a little frill about half-way up, and, when not fully grown, looks like a half-open parasol, opening quite flat when full-grown. A mature specimen will measure 9 inches across and cannot readily be mistaken for any other species. The gills are quite white and the skin is brown and rough. A young specimen cooked like an ordinary Mushroom has a very pleasant flavour and is quite wholesome.—N. L.

Salad of the week.—Where Lettuces get hard at this season a good salad is made of Tomatoes, fresh and of the best quality, and Cucumbers sliced thin. The Tomatoes are scalded to get off the skin and then sliced thin, only oil and a little Lemon-juice to be used if any acid is desired.

OUTDOOR PLANTS.

KNIPHOFIA NORTHIÆ.

This is the most stately of all the Red-hot Pokers, if not of all the Aloe-like plants that can be grown in the open-air north of London. A fine specimen of a good form of it will attain to about three times the size of *K. caulescens*, a great

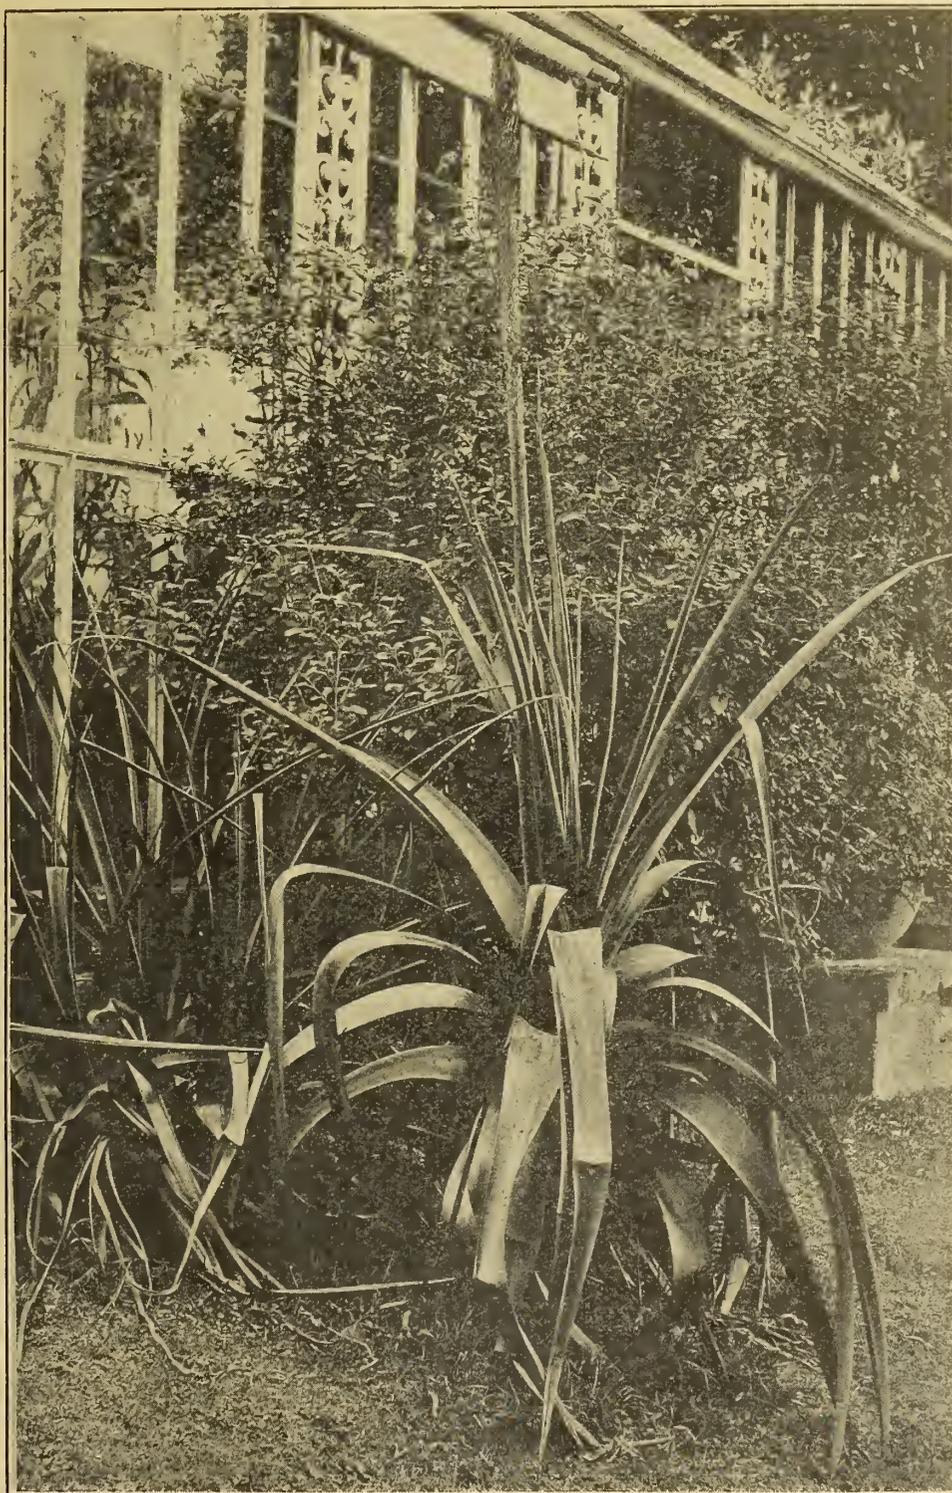

Mr. Beamish, and was gathered from the finest form of the species I have ever seen, in which the leaves are nearly as wide again as those of my larger form.

K. Northiæ is a native of Cape Colony and was found by Mr. W. Dugmore in the neighbourhood of Grahamstown, and was brought to Kew by Miss Marianne North in 1883. It flowered in the succulent-

flowers and their greyish-white extended anthers through the band of newly-opened blossoms of greenish-yellow tipped with orange to the coral-pink buds at the apex.

Unfortunately, this plant had been out of flower for some weeks when the photograph was taken. E. A. BOWLES.

The advent of the Starworts.—When the brightness is fast disappearing from

Kniphofia Northiæ at Myddelton House, Waltham Cross, N.

deal depending on the form grown. As may be seen in the accompanying illustration, the plant with three crowns to the left has much narrower leaves and a meaner habit than the flowering plant that occupies the centre of the picture. Both, however, were raised from one seed-pod, and, from their early youth, have shown their respective characteristic differences. The seed was given to me by

house in 1889 and was described by Mr. J. G. Baker and named after the lady who introduced it to Britain. There is a good portrait of it among her wonderful paintings in the North Gallery at Kew. The flowers are a trifle dull in colouring as compared with the many scarlet and orange *Kniphofias* now obtainable, but a spike in full flower is a fine sight as it shades upwards from the fully-expanded

our gardens, then come the Starworts with their cheery blossoms. Some of the earliest bloom in August, but it is in the latter part of September and October, when other things in the garden are beginning to have a worn-out look, that we appreciate them most. Few subjects in the garden reward the grower with a greater profusion of blossoms in comparison to the little trouble they need. That

they will grow in almost any kind of soil, and yield a fair return of bloom, many readers, especially those who live in towns, can testify; indeed, it is as town garden flowers that many who grow them know them best. In view of the season of blooming, I would suggest to those who have not taken much interest in them up to now the desirability of seeing, if possible, a collection in bloom. Late in the autumn, if the weather is mild, they may be shifted, but in March they may be removed without any fear, and, to obtain the best results, a well-manured soil is necessary. In an open autumn one may cut blossoms far on into November. Starworts, to give the best results, should be planted in bold masses, the varieties being selected with care. It is advisable to divide Starworts every two or three years at the latest, as the plants are apt to get ungainly, and the size of the flower is lessened.

MIGNONETTE.

I THINK it may be safely said that this is the most popular of all the annuals now in cultivation. Opinions differ as to the respective merits of flowers distinguished by their fragrance, but the sweet and delicate odour of the Mignonette is appreciated by all. It has but one defect in recent years, in that it has become liable to the attacks of a disease which, in some soils, renders its culture very uncertain. Thirty years ago I could grow Mignonette with the greatest ease; nowadays it is so extremely capricious. The collapse occurs just when the plants come into bloom, and they die off in two or three days. Why this occurs in some places is a mystery, and I do not know whether it is a fungoid disease or whether it is a form of canker, or whether there is something lacking in the soil which is absolutely needful for its well-being. If the evil were in the soil the remedy would be fairly easy. I mean to try what burnt refuse will do. This material, in a general way, exercises a very marked, and in some cases a magical, influence on vegetation. Where Mignonette is so uncertain it is advisable to sow several times at intervals of a fortnight from the beginning of April, as one of them may be successful. In the case of

POT CULTURE there is no difficulty whatever; anyway, I have never found any, and this is why I fancy that it is a matter of soil, as, when plants are grown in this way, the compost is carefully selected. Seeing how very popular this annual is I often wonder that window gardeners do not favour it more. The fragrance of Mignonette is so grateful that one cannot have it too near the dwelling, and if several sowings are made it can be enjoyed for several months in the year, and the culture is so simple. Fill $4\frac{1}{2}$ -pots with nice, free, loamy compost, with a little leaf-soil, sow a dozen seeds, and stand the pots in the open. The last sowing should be made in the latter end of August, as the seedlings will then be just strong enough to pass the winter and will be ready to respond to the influence of spring weather, and will come into bloom by the time plants are coming up in the open ground. The London market growers produce very fine samples of Mignonette early in spring from seeds sown as soon as the days begin to lengthen. The plants are grown along in gentle warmth without check, with a certain amount of atmospheric moisture. In former years the plants were plunged in fermenting material consisting of a mixture of dung and leaves, which gave out a mild and moist warmth. It was said in those days that Mignonette could only be grown to perfection early in the season

in that way, and it was also said that some growers allowed no drainage, the pots being made without it, and the plants, being plunged in damp material, no water was required during the period of growth. I cannot say if this was true, but very fine samples grown on gentle bottom-heat came from market growers in those days. Sown late in summer for spring blooming, water must be given very carefully during the dull months. A little excess in this way will cause the young plants to damp off, and they must have plenty of light, with a free admission of air in mild weather. In the dwelling the same rule applies. They must be wintered in a cool room, in the living-room they would become so drawn that they would have no power to bloom satisfactorily in spring.

TREE MIGNONETTE.—I wonder how many grow tree Mignonette nowadays. I have not seen any for many years, and have seen no mention made of it. In former years many amateurs prided themselves on possessing specimens some years old. It was simply the old variety grown in standard fashion, a straight stem being taken up and a head formed which became broader and the stem more woody each year. It is absolutely necessary that the seed-pods be picked off as soon as they form, and very great care must be taken in watering in the winter. BYFLEET.

AMONG THE HARDY FLOWERS.

ASTER ERICOIDES DELIGHT.—The ericoides varieties of the Starwort are all pretty, so much so, in fact, that it is difficult to make a selection. These ericoides varieties, with their Heath-like foliage, pretty habit, and multitude of small flowers, are exceedingly useful, especially as cut flowers. In the border they possibly have not the effect of the big-flowered varieties, but they are graceful and beautiful enough to win the heart of everyone who loves hardy flowers. The blooms of Delight are white, and sprays from the plant make a lovely decoration. These Heath-like Starworts receive too scant attention in most gardens, and are too frequently crowded up among other plants in a way which robs them of their character and much of their beauty.

ANTHOLYZA PANICULATA MAJOR.—Is not this an over-rated plant? It is, at all events, very disappointing even to those who know the ordinary Antholyza paniculata, which has a better colour than the variety major. The latter is a bolder grower, it is true, and when in leaf is handsome, with its long-ribbed or plaited leaves. The flowers are dull in colour. I may be called to account for "slating" this plant, but it is only fair to warn other amateurs that it is a disappointment, and inferior to the smaller-growing typical Antholyza. I have found both of these hardy if planted 5 inches or 6 inches deep when in light soil (about 4 inches in heavy loam), and covered with some litter or ashes the first season after planting. In subsequent years they are apparently hardy, especially if the old foliage is left on until all danger from severe frost is passed.

IS THERE A HARDY DAHLIA?—I am induced to ask this question through a very old gardener whom I knew assuring me that even in the north of England he had found the old Cactus Dahlia Juarezii stand most winters with a covering of ashes, and even without that in sheltered borders.

THE CROSSWORT (*Phujopsis stylosa*) (syn. *Crucianella stylosa*).—I always prefer to call this the Crosswort. It is quite a pretty plant and excellent for a rockery, but it has two faults which it may be as well to discuss before giving its good

qualities. One is that it is inclined to spread rapidly at the root when established. It is not very difficult to keep in bounds, but should, all the same, be kept away from tiny and choice plants. The other failing is its strong odour, which is most pronounced in the evening or after rain. I cannot, therefore, recommend this Crosswort for planting close to the house or by a much-frequented path. Still, it is not to be ruled out, as the trailing stems have pretty foliage like that of the common Woodroof, and the rounded heads of small pink flowers are quite pretty, the projecting styles, which give the plant its specific name, adding lightness and grace to the blooms.

MILDEW ON MULLEINS.—I wonder why mildew has been prevalent on some of my Verbascum and not on others! It disfigures the leaves very much, but it has not spread very greatly and most of my plants are free from it. It evidently attacks the white-leaved Verbascum worse than the green-leaved ones, as I have some plants of Verbascum phœniceum which are quite free from it. One plant of Verbascum Chaixi is badly affected, while another close by is free. Some plants of Verbascum olympicum are badly hit, but the majority are not touched. I am fond of these Mulleins and they seed freely, so that, although biennials, as a rule, they are as good as perennials. By the way, both V. Chaixi and V. phœniceum are perennial with me.

AN AMATEUR OF HARDY FLOWERS.

SOME UNRELIABLE LILIES.

LILIUM NEPALENSE is one of those tender Indian Lilies that cannot be depended upon in the open ground. Even if it be protected in winter it flowers, as a rule, so late that the cold nights check the development of the blossoms. From its distinct and striking appearance it is well worth the protection of a greenhouse, but even here it is difficult to establish it permanently. It is of tall, slender growth, the flowers, which reflex a good deal, like those of L. Martagon, being greenish-yellow or yellowish-green, with a purple base to the segments. The extent of the purple marking and the depth of colour vary a good deal in different individuals. The stock of this Lily has hitherto been kept up by annual importations, but it is probable that before many years it will almost die out, a fate which has befallen another Indian Lily.

L. NEILGHERRENSE, which in the 80's of the last century was sent here in considerable numbers and now seems to have quite disappeared, that is, so far as its culture in this country is concerned. This is a late-flowering species, its long trumpets being of various shades of pale yellow or primrose. A peculiarity of L. neilgherrense is that the stems, after they leave the bulb, often travel underground for some distance before they make their appearance. Another pretty Indian Lily now seldom seen is

L. LOWII, whose white thimble-shaped blossoms are spotted in the interior to a greater or less extent with purplish-crimson. It flowers, as a rule, in the summer. The hardiest and the most accommodating of these Indian Lilies is

L. SULPHUREUM, which was first distributed under the name of L. Wallichianum superbum. This, of which some near relatives have been found in China, has become established in the milder parts of the country. It is of tall growth, with narrow, densely-arranged leaves, and long, widely trumpet-shaped flowers of a yellowish tone. A marked peculiarity is the

presence in the axils of the leaves on the upper part of the stem of a number of comparatively large bulbils, which afford a ready means of increase. K. R. W.

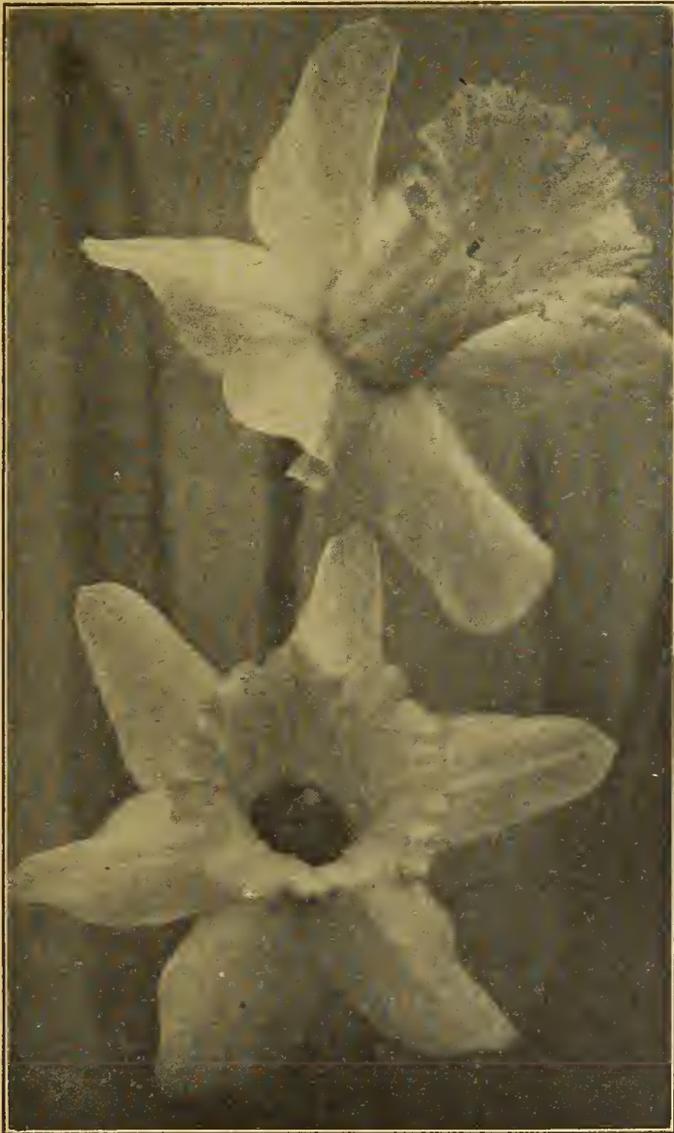

DAFFODIL, FLORENCE PEARSON.

This is a magnificent pale sulphur-coloured Daffodil, the result of a cross between Emperor and Mme. de Graaff. It has a creamy-white perianth of good texture and long, pale sulphur trumpet frilled at the edge. It is a vigorous grower, with foliage as large and strong as that of Emperor. F. W. G.

Potting Carnation layers.—I do not, as a rule, advise potting Carnation layers in

late the plants during the dull, dark days. Pot firmly, one plant in a pot, and plunge them to the rim in fine ashes or Cocoa-nut fibre in a drip-proof frame. If drip reaches the plants it will ruin them. Do not over-water them from November to February, and expose them to all the air possible, avoiding, of course, cutting winds, and cover the frame with mats in case of very severe frost. Plant out at the end of March.—T.

Ourisia coccinea.—I hope I did not misunderstand Mr. Jenkins in his note, page 387, the object of which was admirable. My idea in the last note was simply to express the opinion that your highly competent and experienced contributor's advice to divide and

Narcissus Florence Pearson.

autumn, with a view to planting them out in spring, as, provided the plants are strong and well rooted, they always give the best return when planted at the end of September or quite early in October. All the same, where the situation is low or the soil very cold and retentive, or if the layers are late and badly rooted, I pot them in October and give frame protection during winter. This, indeed, is the only way of succeeding with delicate varieties. Three-inch pots are best for potting them in, and care must be taken that the delicate rootlets do not suffer from exposure during the operation. Loam, pure and simple, with the addition of coarse sand or grit to keep it open, forms the best compost, as it is best not to stimu-

replant occasionally would not meet the difficulty. This is confirmed by the remarks of Mr. Cornhill on page 440. Readers interested in *Ourisia coccinea* will find there a confirmation of my own views and experience.—S. ARNOTT.

Colchicum variegatum.—The variegated Meadow Saffron is the cheapest and most reliable of the Colchicums, with distinctly marked chequering. It is not so soft in its colouring or so large as *C. Sibthorpi*, which is expensive and does not stand so well everywhere. *C. chionense*, or *Parkinsoni*, is finer than *C. variegatum* in many ways, but it is generally too late to give much satisfaction, except in favoured places. *C. variegatum* comes early. It has sharply pointed segments, which are light purple chequered with a deeper tone. The first flowers of *C. variegatum* appeared this year on September 6th.

ROYAL HORTICULTURAL SOCIETY.

SEPTEMBER 26TH, 1916.

THE meeting held on this date was materially augmented by the holding of the annual exhibition of vegetables in conjunction therewith. As usual, the vegetables showed high cultural excellence, and in not a few instances the competition was keen. In the flower section there was much to admire, the hardy flowers shown worthily demonstrating the best of such things at this season. Roses, too, from a variety of sources, showed much colour-richness, while affording proof of those varieties good in the autumn. Carnations, Dahlias, Michaelmas Daisies, Early Chrysanthemums, with shrubs valuable for distinctive leaf character or richly-coloured foliage, each contributed their quota. Some good novelties, referred to more fully elsewhere, were also on view.

HARDY FLOWERS.

These were worthily displayed by Mr. James Box, whose bank of them extended from the entrance to the fruit annexe. Rarely have these things been better shown, the liberal groups very suggestive of what is possible with them in the open ground. Backed throughout with Golden Rods, Miss Mellish Sunflower, and the finer Michaelmas Daisies, all else resolved itself into free massing. A good centre consisted of *Cimicifuga simplex* and *Scabiosa caucasica*, pure white and pale mauve-blue respectively. Even more conspicuous, by reason of colour, was the magnificent lot of *Aconitum Fischeri* and *A. Wilsoni* (dark and light blue respectively), and of much value, because of their long flowering. Two good varieties of the Italian Starwort, *Beauty of Rousdorf* and *Perry's Favourite* (the former large and of a good light violet-blue tone, the latter lilac-pink and rather pretty). *Helenium* in golden and crimson-brown, both forms of *H. grandicephalum*, were effectively shown. Scarlet Geums, richly-coloured Phloxes, and good *Delphiniums* (the sky-blue *D. Belladonna* fl.-pl. particularly good among them), and the crimson of *Lobelia Queen Victoria* were other telling bits of colour. *Lobelia Tupa* was also well shown, and in a group it at once commands attention. Some plants of interest were staged by Mr. G. Renthe, and here, of conspicuous beauty, was the pure white *Meadow Saffron* (*Colchicum speciosum album*). The big white flowers stand up boldly and are in sharp contrast with those of the red-purple form. *Escallonia oregana*, with rosy-red terminal trusses, is also excellent. *Berberidopsis corallina*, *Clethra arborea*, with white, fragrant bells in pyramidal panicles, and the Chilean Nut (*Guevina avellana*), with whitish flowers, were among other things shown. *Schizocodon ilicifolius*, *S. soldanelloides*, and *Astilbe simplicifolia* were among rare alpinas. A novelty of great charm from Mr. Clarence Elliott and which gained an Award of Merit was *Gentiana ornata* variety, a lovely thing from the Himalaya for which no praise is too great. The leaves are linear, firm, and almost fleshy, the solitary, erect, sky-blue flowers produced at the extremities of procumbent stems. Valuable at any time, it is doubly so in September, when choice rock plants are rare. Six inches or more high, it appears to be more robust than some other forms of this somewhat variable species. Messrs. Felton and Sons had a wondrous display of *Physalis Franchetti*, whose brilliantly-coloured calyces are just now very effective. With it sprays of the equally brilliant *Berberis Thunbergi* were associated. Michaelmas Daisies were well

shown by Messrs. H. J. Jones, Limited, a fine representative gathering including Mrs. S. T. Wright, Rycroft Pink, and a variety of the Italian Starwort (*Aster Amellus*). The best things from Mr. W. Wells, junr., who also showed freely of Delphiniums in variety, were *Aster Amellus* King George, the finest of the group, and *Helianthus sparsifolius*, a perennial Sunflower of fine presence and colour, and removed from the common-place. Messrs. W. Cutbush and Son showed *Aconitum Fischeri* and a large gathering of Michaelmas Daisies.

FLOWERING AND OTHER SHRUBS.

This department was rendered more than usually interesting by reason of the presence of more than one novelty. Prominent among them was *Pyrus Vilmorini*, a new Chinese species allied to the Mountain Ash section of the genus, having long, elegant, blue-green pinnate leaves, pale green below, and small clusters of fruits which in colour are not unlike the rose shades seen in *Pernettya*. It promises well. Even more charming was *Clematis Campanile*, a herbaceous kind 3 feet or so high, bearing pyramidal panicles of blue, white-anthered flowers. These are also fragrant. It is said to be a hybrid having *C. stans* and *C. grata* for its parents. It is quite beautiful and a welcome addition to its class. *Euonymus latifolius* was also shown in fruit, the red capsules, orange-coloured berries, and bronzing leafage giving a very pretty effect. Each of these gained an Award of Merit. They were presented by Messrs. George Paul and Son, from whom also came the most graceful and elegant Willow we have seen (*Salix pruinosa*), whose stems and branches are as white as in *Rubus lasiostylus*. Hence it is highly ornamental and distinct to boot. *Ailanthus Vilmorini*, with handsome yard-long pinnate leaves, was another notable shrub in a lot of things which included species of *Rhus* and *Hibiscus* of sorts. Messrs. J. Cheal and Sons also contributed shrubs in variety, *Fabiana imbricata*, *Euonymus latifolius*, *Veronica gracillima*, not unlike *V. salicifolia*, being remarked among many things. *Berberis Thunbergi* was richly coloured. Mr. L. R. Russell's chief contribution to this department was hardy Vines and *Crataegus*, *C. Pyracantha Lælandi* in particular bearing freely its scarlet fruit clusters. *Vitis Coignetæ*, *V. vinifera purpurea*, and *V. Thompsoni* were well shown.

CARNATIONS.

Messrs. Allwood Brothers showed these popular flowers, the display being of a sumptuous character. Among the varieties shown we noted the Clove-scented Bishton Wonder, which is of a new shade of lilac-pink. Mandarin (yellow-ground fancy), Wivelsfield White, Salmon Enchantress, Nora West (one of the most popular of pure pink shades), Mary Allwood, and Princess Dagmar (fine crimson) were some of the best. That last named is particularly rich in colour and of handsome proportions.

ROSES.

Nothing quite new was remarked among these, though the rich and varied displays from a variety of sources afforded proof of the value of the perpetual-flowering character in not a few varieties. In that from Mr. George Prince, Josephine Nicholson stood out prominently, a great stand of it demonstrating colour-beauty and freedom. The long, tapering, pure-white flowers of Mrs. Herbert Stevens, with a profusion of buds, were also noticeable. Hugh Dickson and Mme. E. Herriot were also noted, and a big lot of Snow Queen.

Rev. J. H. Pemberton again showed a set of his new Cluster Roses. In a gathering of twenty or thirty sorts from Mr. J. C. Allgrove, Rayon d'Or was very fine. Messrs. B. R. Cant and Sons also showed excellent stands of these flowers, Lady Hillingdon being especially rich in colour and in some quantity. Snow Queen, Hugh Dickson, Mme. E. Herriot, Lyon Rose, and Duchess of Wellington were remarked among many others.

DAILIAS.

The fact that sixteen novelties were granted certificates at this meeting alone would seem to imply a certain popularity for these flowers. They came from the chief raisers, Messrs. Stredwick, Cheal, Burrell, West, Dobbie and Co., and Mr. Reginald Cory each contributing. The largest collection was that from Messrs. Carter Page and Co. Messrs. Cheal and Son also had a good assortment, showing freely of the Star section, and securing an award for Autumn Star. Crawley Star and White Star are other good sorts.

FERNS.

A large table group of these from Messrs. H. B. May and Sons included several of the newer *Nephrolepis*, as *N. gracillima*, *N. Whitmani compacta*, *N. Willmottæ*, and others. *Pteris Summersi*, *Davallia gibberosa*, and *Adiantum Veitchi* (one of the most beautiful of its race) were noted. Quite a nice assortment of the hardy evergreen *Scolopendrium* was also shown.

ORCHIDS.

The outstanding Orchid novelty was *Sopho-Cattleya Sir Mervyn Buller*, with rosy-salmon sepals and petals and rich red-crimson lip. The *Cattleya* influence is strongly revealed (first-class certificate). *Lælio-Cattleya Lady Manningham Buller*, with soft yellow petals and glowing crimson lip gained an Award of Merit. Both were shown by Messrs. Armstrong and Brown. *Cattleya Rhoda* (Langley variety) has reddish sepals, salmon-coloured petals, and big, heavily-goffered lip of ruby crimson, with gold-coloured veins. It was from Messrs. Flory and Black. *Brasso-Cattleya Oberon*, var. *Majestic*, is a large-flowered variety of most delicate lilac-mauve colour throughout. It was shown by Messrs. Sander and Son. Each of the above gained an Award of Merit. Orchid groups were shown by Messrs. Sander and Son and Messrs. Charlesworth and Co.

FRUIT AND VEGETABLES.

Of fruit, the most attractive exhibit was that of two-year-old and three-year-old upright cordon trees of Apple Rev. W. Wilks from Mr. J. C. Allgrove. Lifted from the open quarter, the cordons, not exceeding 3½ feet high, were bearing in some instances as many as a dozen handsome fruits. The younger trees bore one—occasionally two—fruits of huge size. To demonstrate the development of the Runner Bean, Messrs. Sutton and Sons showed a series of pods on a board, starting from the old Scarlet Runner, with curved, thick-looking pods, and proceeding by way of Champion, Ne Plus Ultra, and others, till Prizewinner and Best of All, with pods nearly 18 inches long—young and succulent withal—are reached. Despite their length, these have pods about an inch wide. Quite a collection of French Beans and others having coloured pods was also on view.

Owing to lack of space we have been compelled to hold over till next issue our notes on the vegetable show. A complete list of plants certificated and medals will be found in our advertisement columns.

THE WEEK'S WORK.

OPEN-AIR GARDENING.

IN BLOOM SEPTEMBER 27TH.—*Clerodendron trichotomum*, *Buddleia variabilis magnifica*, *Ceanothus* (in variety), *Hardy Fuchsias* (in variety), *Wistarias*, *Solanum jasminoides*, *Myrtle*, *Clematis* (several varieties), *Polygonum baldschuanicum*, *Hydrangea paniculata grandiflora*, *Magnolia grandiflora*, *Calycanthus occidentalis*, *Genista hirsuta*, *Spartium junceum*, *Lavatera Olbia*, *Nandina domestica*, *Berberis nepalensis*, *Eupatorium Weinmannianum*, *Shrubby Veronicas* (in great variety), *Clethra alnifolia*, *Hypericums* (in variety), *Ericas* (in variety), *Roses* (in variety), *Caryopteris Mastocanthus*, *Artemisia lactiflora*, *Polygonums* (in variety), *Cyperus longus*, *Chrysozonum virginianum*, *Tritomas* (in variety), *Water Lilies*, *Lilium speciosum*, *Gladioli* (in variety), *Hyacinthus candicans*, *Belladonna Lilies*, *Montbretias* (in variety), *Anchusa Opal*, *Achilleas*, *Oenotheras* (in variety), *Pentstemons* (in variety), *Linum arboreum*, *Scabious* (in variety), *Statice* (in variety), *Anemone japonica* (in variety), *Lobelia cardinalis*, *Helianthus* (in variety), *Michaelmas Daisies* (in variety), *Erigerons* (in variety), *Heleniums*, *Rudbeckias*, *Salvias* (in variety), *East Lothian Stocks*, *Antirrhinums* (in variety), *Potentillas*, *Eupatoriums*, *Dahlias*, *Cosmos*, *Chrysanthemums* (in variety), *Gypsophilas*, *Perpetual-flowering Carnations*, *Leptosiphons*, *Cerastiums*, *Verbena venosa*, *Cannas*, *Tufted Pansies* (in variety), *Gazania splendens*, *Begonias*, *Petunias*, *Verbenas*, *Calceolaria amplexicaulis*, *Ageratum*, *Phloxes*, *Tropæolum speciosum*, *Mesembryanthemums*, *Sedum spectabile*, *S. Sieboldi*, *Oxalis*, *Myosotis*, *Omphalodes cappadocica*, *Linarias*, *Silenes*, *Androsaces* (in variety), *Hutchinsia alpina*, *Convulvulus mauritanicus*, *Tunica Saxifraga*, *Dwarf Campanulas* (in variety), *Plumbago Larpenæ*, *Pratia angulata*, *Dryas octopetala*, *Ethionemas*, *Vaccinium*, *Vitis idæa*, *Platystemon californicus*, *Agapanthus umbellatus*, *Cimicifuga racemosa*, *Sweet Sultan*, *Agathæa cælestis*, *Virginian Stock*, *Arabis*, *Cyclamen hederifolium*, *Colchicum autumnale*.

THE WEEK'S WORK.—There has been a good crop this year of seeds of flowers and shrubs, and close attention is still required to gather as they ripen such as are required for next season. A portion of Delphiniums and herbaceous Pæonies has been lifted carefully, divided, and replanted. They begin their growth quite early in the spring, and they rarely do well if removed late in the autumn. Pæonies especially are extremely impatient of removal. The ground for them should be deeply trenched, and a good supply of rotten manure dug into the bottom spit deep enough for the roots not to reach it when first put in. If the soil is heavy a little leaf-mould should be worked into the top spit and round the roots. Delphiniums can be planted with good effect almost anywhere—in beds, in clumps, in the shrubbery, in mixed borders, or by the banks of a lake or stream. Pæonies, also general favourites, will thrive almost anywhere in well-prepared soil, and are very attractive in the flower borders of the kitchen garden. A border devoted entirely to the different varieties of this flower is extremely effective, the plants lasting in bloom over a long period. There are many lovely varieties now to be obtained in all shades, from white to deep crimson. Polyanthuses and Primroses raised from seed sown in the spring and afterwards planted out into nursery beds are now being transferred to their permanent positions, adding plenty of leaf-mould and decayed manure to the soil. They bloom very early in the spring, and a succession of flowers is obtained over a long period by placing some in warm, sheltered positions and others in more exposed places. The layers of Carnations are now well rooted, and will be potted up into 4-inch pots, using a good compost and making very firm. The pots are then plunged to the rims in coal-ashes in a frame and the lights only placed on when it rains. The planting of Wallflowers, Myosotis, and other biennials has been commenced, and will be completed as soon as possible. Dry weather is preferable for this work, as treading on freshly-dug ground while in a wet,

sticky condition does a great deal of harm. Most of the Wallflowers look well edged with Forget-me-not, so that with these two species there need be no clashing or undesirable combinations. Canterbury Bells are also best planted in autumn, although early spring will give good results. This is a true biennial and few plants make a finer display in their season. They do admirably on a north border, and in this position their season of blooming is considerably prolonged.

F. W. GALLOR.

Lilford Hall Gardens, Oundle, Northants.

SOUTHERN COUNTIES.

Melons.—Plants to supply ripe fruit at the latter end of October and early in November will need every encouragement in the way of heat and stimulating at the roots, at the same time making use of every ray of sunshine to secure high temperatures, which are not only an economy but far more beneficial and of greater forcing value than artificial heat. The nature of the stimulants may be varied according to circumstances, but whatever they consist of they should be applied in a liquid state and in a tepid condition. Care has to be taken to see the soil does not become dry before supplying water, otherwise both roots and fruits will receive a check and the latter be liable to crack afterwards. As the fruits swell and increase in weight see that the supports are secure and that the trellis wires through contact will not damage them. Keep all lateral growths, so long as the main leaves are sound, closely pinched, and promote a humid atmosphere by the usual means of damping and syringing daily. In some seasons black-fly is apt to be very troublesome on Melons in the autumn. The best way of dealing with it is to vaporise the house directly its presence is detected. Melons now ripening should be kept warm and dry, but until properly finished the plants must not be altogether dried off at the roots. As soon as the crop is cleared the house should be washed down and got ready for winter Tomatoes, which, if already in pots, as they should be, have simply to be transferred from one house to another in cases where the former is unsuitable for the purpose later on and in the depth of winter.

Figs.—As the late houses are cleared of their crops, whatever may be necessary in regard to root-pruning, restriction of the roots by enclosing them within certain limits by means of 4½ inch brick walls built with cement, or adding to existing borders in the case of recently-planted trees, should be carried out. Where trees are grown in raised borders enclosed by walls, pigeon-holed on their fronts and sides for the purpose of admitting warmth when surrounded with a bed of leaves when forcing is commenced, the latter is now best taken away, when all roots which have escaped and penetrated the decayed leaves should be cut back to as far within the pigeon-holes as it is possible to do. The houses must be kept fully ventilated and the borders on the dry side, but not so dry as to cause a premature fall of the leaf. On fine days a copious washing of the foliage may still be indulged in.

Early Peach-house.—The foliage has ripened fast and will soon be dropping. As soon as all the leaves have fallen the trees should be overhauled and relieved of surplus wood, as well as any of the old bearing wood still present. This work can, if necessary, be postponed till a wet day occurs—i.e., if time cannot otherwise be spared. If any structural alterations or repairs are necessary they should be undertaken without further delay, and the same with regard to the painting of either the interior or exterior woodwork. If nothing but a general clean down of the house is required this can be held in reserve for wet weather. In that event the loosening of the trees from the trellis and the tying of the wood in bundles to facilitate the cleaning of the roof-glass should not be done until cleaning is commenced, as the buds in the interior of the bundled-up branches are apt to start prematurely if they remain so for any length of time. The rettying of the trees to the trellis can also be done on the same principle, so that labour shall not be absorbed when, so long as fine weather prevails, it is required elsewhere. The

trees should be dressed with an insecticide or sulphur before tying. See that the border is in a thoroughly moist state, ascertaining if such is the case by an actual test and not trusting to appearances.

Late Peach-house.—As soon as the fruit is gathered the trees should be looked over and relieved of the old bearing wood, and, as far as it can be done, of surplus current season's growths also. This thinning out allows sunlight and air more free play to ripen the wood. Such operations as adding to and top-dressing of borders, the lifting of roots to check undue growth where they have got out of bounds, or the trees are in ill-health as a result of the border being in an exhausted condition and a partial or total renewal of border has become imperative, should be undertaken now. The best loam obtainable is necessary for Peach-growing, and the more lime it naturally contains the better is it suited to the purpose. Where the lifting of a tree from the outside walls to make good a vacancy under glass is contemplated the hole for its reception should be made ready, new drainage put in if required, also the compost for enclosing the ball prepared, so that the lifting and transplanting of the tree itself can be carried out during the first half of next month.

Mustard and Cress.—The supply of both should be fully maintained by sowing every few days, the little-and-often principle being more satisfactory than sowing a greater quantity at less frequent intervals.

Watercress.—If the plants in the oldest beds have been cut over, when about to run to seed, close to the surface of the water, there will now be an abundance of young tops available for the salad-bowl. Beds which have been in bearing for some time past and now getting past their best should be cut down for the purpose of furnishing a good supply for the winter.

Beet.—The remaining roots in the bed of the earliest-raised Globe Beet should, if not too large, be pulled and stored for present use; the same with regard to the roots resulting from the second and third sowings, as they are now sufficiently large for table use.

Celery.—If not already done, the moulding up of the plants intended for the earliest supply should be completed at once. The heads will then be ready for digging in the early part of October.

East Lothian and other Stocks.—Where these are appreciated in early spring for greenhouse and conservatory decoration, it is necessary to now raise the plants. Unless an unusually large number of plants is required, a 7-inch pot of each of the varieties Scarlet and White Lothian, All the Year Round, Princess Alice, and Empress Elizabeth will furnish a sufficient number for all ordinary purposes. The best place to raise them is on a shelf in a greenhouse, keeping the seeds shaded until germination takes place.

A. W.

MIDLAND COUNTIES.

Peaches and Nectarines have done exceptionally well here this season, the fruits finishing well and of first-rate quality. With the exception of a few late varieties, the crop has been gathered. The trees will now be cleared of all wood that has carried the crop, and superfluous side growths shortened to the basal buds, afterwards giving the trees a thorough washing with an insecticide. All mulching materials will now be removed, so that the sun may the better warm the borders containing the roots. Point over the surface soil with a fork, and if too dry give a soaking of water, which will suffice for some time to come, as the days are getting shorter and the sun less powerful. It is of little use to fork these mulchings into the borders, for after the exposure and rains to which they have been subjected they contain but little nourishment. Most kinds of wall trees will soon be in a suitable condition for replanting, and advantage should be taken of fine weather to do any necessary transplanting or rearranging. All vacant places on walls should be furnished with young healthy trees. Before planting, the old soil should be removed and replaced with fresh turfy loam. If the soil is

of a clayey nature, very little, if any, manure should be added to it, but if it is sandy or gravelly, with a porous subsoil, then a moderate proportion of well-decayed manure may be mixed with it. When planting fruit-trees in heavy land it is advisable to plant on mounds, raising a heap of soil a little above the ordinary level, but when dealing with a gravelly staple, plant in a slight depression, so that the roots may obtain all the moisture possible. Fruit-trees growing in poor, hungry soils require liberal treatment to induce them to make moderate growth, but, as a rule, they fruit freely, the wood being usually well ripened, although the fruits are not as a rule large.

Vineries containing ripening Grapes now require careful ventilation or the shortening days and cold, damp nights will result in the berries being mildewed or rotting. As late Grapes are generally required to hang upon the Vines for some time, it is necessary that they should be thoroughly ripened. Encourage the ripening by a judicious use of fire-heat, and maintain a dry, warm atmosphere. On sunny days admit air freely, but if the weather is dull and damp open both top and side ventilators very slightly only and maintain sufficient heat in the pipes to keep the temperature about 60 degs. If a mulch of clean straw is applied to the border it will check evaporation, thus saving the necessity of frequent watering.

Chrysanthemums.—All must now be housed, except, perhaps, the very latest-flowering varieties. Before the plants are removed indoors clean the pots and spray the foliage with a solution of sulphide of potassium. Avoid overcrowding, as this always leads to disappointment. If the plants are overcrowded when removed to the houses the flowers are bound to suffer. For some time after the plants are removed indoors they should be given liberal ventilation by night as well as by day, taking care at the same time to prevent cold draughts. It is advisable to fumigate or vaporise the plants on two or three occasions at intervals of five days or six days to make certain that thrips or aphid will not disfigure the flowers. Watering must be carried out with care, and the strength of manure-water or other stimulants gradually decreased.

Lilium longiflorum giganteum.—The second batch of retarded bulbs was potted during the week, placing the largest bulbs in 32 size pots and the smaller ones in 48's. The compost used was good loam, leaf-mould, decayed cow-manure, coarse sand, and a little wood-ashes. Sufficient room is left in the pots for a top-dressing later on. The pots are afterwards stood in a cold-frame and covered with leaf-soil, this being removed as soon as the bulbs start into growth.

Cauliflowers.—Plants from the first autumn sowing will now be large enough for planting out in cold frames for the winter. If the plants show signs of flagging after planting, keep the frames rather close for a few days until the roots become active, after which air should be admitted freely, removing the lights in favourable weather throughout the winter.

Spinach.—The plants of the second sowing are ready for thinning, an operation that needs to be done before the plants become crowded and drawn. Overcrowding is liable to cause mildew, especially in low-lying districts. A distance of 2 inches should be allowed between the plants in the row. In order to promote the growth of large, healthy leaves give frequent light dustings of soot and hoe the ground between the rows as often as possible. The largest leaves should be gathered from the early-sown plants, whether required for cooking or not, to encourage the growth of young, fresh leaves. Old leaves that have lost their deep green colour are of no value whatever.

Seakale intended for early forcing should have all decaying foliage removed in order to expose the crowns to the weather.

Autumn-sown Onions.—The seedlings are appearing above the ground, and as soon as it is safe the Dutch hoe will be used between the rows and a light dusting of soot given.

Maincrop Onions.—Advantage will be taken of wet days to clean, sort, and rope Onions.

The loose outer skins should be removed and all roots showing the least sign of decay rejected. The bulbs should be kept distinct in respect to variety, and roped according to size, those with thick necks being put on one side for immediate use. The smallest of the bulbs may be used for pickling, although those of the Silverskin variety are usually preferred on account of their better appearance. The ropes of Onions should be suspended in the coolest shed available, an open shed answering for well-ripened bulbs, which merely require to be kept dry.

Winter salads.—Every available cold pit will now be filled with Lettuces and other salad plants, so that they may become established before winter. From seeds sown at the end of August plenty of strong plants suitable for planting in pits is available. The soil is raised to within 15 inches of the glass, and trodden firmly whilst moderately dry. A distance of 9 inches is allowed between the plants.

Parsley should not be allowed to become over-grown or the leaves will lose their colour. If the foliage is cut down now and a good watering given the new growth will be of a much better quality and the plants will withstand the winter better than if left uncut.

F. W. G.

SCOTLAND.

Onions.—These have now been harvested and laid out to ripen off in a well-exposed place at the foot of a south wall, the coping of which is of glass. In such a place, with anything like favourable weather, the drying off is not prolonged, and to hasten this the Onions are turned occasionally. The crop is a fairly heavy one, and with but routine attention several bulbs were noticed which were each nearly 3 lb. in weight. The bulk, however, would probably run from 1½ lb. to 2 lb. each—quite large enough. These, of course, were from planted-out seedlings raised in heat. Sown-out Onions are, by comparison, equally good. These were sown early, and finally thinned to 4 inches apart, so that the bulbs have attained to quite respectable dimensions. A cool, dry, frost-proof place is needed if Onions are to keep satisfactorily. If the atmosphere is damp, rotting is inevitable; while, if the temperature be too high, growth is prematurely excited and the bulbs become soft and useless. In the course of the week the Onion bed sown in August was hand-weeded, and the hoe was afterwards run between the lines. This cleaning, it is expected, will suffice until growth begins once again in spring. In the case of these Onions germination has been quite exceptionally good, and as the bed is under the lee of a Beech hedge it is anticipated that the seedlings will come through quite well even should the winter be severe.

Winter vegetables.—The growth of winter vegetables during the season has been somewhat erratic. Some things, such as Brussels Sprouts and Curly Kale, have grown remarkably well. On the other hand, Savoys, with the exception of Early Elm, have made, so far, but moderate progress. In view of this, a dressing of concentrated artificial manure was applied in the course of the week, and the hoe was rather deeply run through the quarter. Autumn Cauliflowers, upon which some reliance was placed, are not promising. Should frosts hold off there will be plenty of heads, but at a much later date than is customary. Cabbage planting was completed for the present during the week. The variety First and Best is a small one, therefore the plants were put out rather thickly—about 14 inches each way being allowed. A drill about 4 inches deep is taken out with the hoe in which the young Cabbages are planted. When growth is sufficiently advanced the soil is again hoed back into position, so that the base of the plant rests on the soil. In the case of these small early Cabbages this does away with the necessity of moulding up, which is not really necessary. Should slugs show signs of activity, a dressing of soot will be given.

Peas and Beans.—Continue to remove spent straw of Peas and Beans as soon after the crops are picked as may be possible. In the case of Pea straw this is worth emphasising,

for mildew may be present and the spores will readily affect other things. If sufficiently dry, the straw may be burned; if not, let it be removed to the rot-heap. An alternative way of disposing of the straw of Peas and of Beans is to bury it when trenching; but it is to be feared that in the majority of gardens trenching will not be so general as has hitherto been the case.

Late Potatoes.—The time is at hand when late Potatoes must be lifted. Fears are now entertained that disease may prove more prevalent than was at one time anticipated, so the lifting of the crop may be hastened by a week or so if the weather remains favourable.

Hardy wall fruit.—Picking is being attended to as becomes needful from day to day. Plums are now ripening freely, and, after all, are a fairly good crop. In the case of Coe's Golden Drop the yield is very heavy. This valuable dessert Plum, in a general way, ripens here in late September. It will be later this season, and in order to expose the fruit to the sun as far as possible obtrusive leaves have been removed. Pears, too, are now being picked. It may be interesting to note that Williams' Bon Chrétien is exactly a month later than was the case last year. Peaches, although hindered by lack of sun, have turned out fairly well, both as regards quantity and quality. Nectarines, always a more precarious crop on south walls, will, if sunshine continues, be fairly satisfactory, although Elruge is small.

Wallflower.—A bed of Asters having become rather shabby, these have been pulled up, and the bed, after being lightly manured and dug, will be refilled with Wallflowers. The varieties of Wallflower used this year are limited to Harbinger, Blood Red, and Belvoir Castle—three very useful and reliable sorts, if now rather old.

Salvias, etc., for winter flowering.—In order to encourage the formation of fibrous roots in the neighbourhood of the necks of the plants, the spade has been run round about a foot from the stem. This gives them a certain check for a short time, but they soon recover, and when lifted and potted up they suffer but very slightly. Among the subjects thus treated during the week may be mentioned *Salvia splendens*, *S. lactiflora*, *S. rutilans*, *S. Pride of Zurich*, *Eupatoriums* of kinds, and a considerable batch of late-struck *Chrysanthemums*. The last were struck in May, and planted out in mid-June. They are now fine healthy pieces, and can—most of them—be accommodated in 7-inch and 8-inch pots, which are sufficiently large for their requirements, and in which the plants are useful in many ways.

Berried plants.—A look round the shrubberies in the course of the week shows that the crop of winter berries will be but mediocre. Hollies in some exposures will bear fairly good crops, but there is a much larger proportion of barren trees than is usual. *Cotoneaster frigidus*, another favourite, is likely to carry a useful amount of its showy berries. Barberries of kinds were very heavily cropped, *B. Darwini* in particular, but birds are very partial to the fruits of these shrubs, and when they are ripe the berries are cleared off in a short time. Thorns, of course, are beginning to colour up their fruits, but, as in the case of the Barberries, birds take a heavy toll. Conspicuous are the hips of Sweet Brier, and especially so those of *Rosa rugosa*.

Under glass.—During the week the work has been entirely routine. The necessary watering is attended to early in the morning, and ventilation is afforded as the outside temperature warrants. Among greenhouse plants in bloom just at the present time may be mentioned some examples of *Nerines*—*N. Bowdeni* and *N. Fothergilli*. These are very bright and showy things, although they have a rather bare appearance owing to the fact that the flower-spike develops before the foliage. Nevertheless, they are worth attention, and they are very showy while in bloom. In the stove let the firing be as moderate as possible. No advantage is derived from an excessively high temperature; as a matter of fact, such a condition may lead to an outbreak of insects. W. McGurros.

Balmac Gardens, Kirkcudbright.

CORRESPONDENCE.

PLANTS AND FLOWERS.

Wintering Cannas (C. W.)—As soon as frost destroys the foliage take them up, cutting the stems down to within 4 inches of the soil. The small shoots may be left on them. Leave a portion of soil round the roots, and store them away in any cool place, where frost does not come, until May, or they may be buried in a frost-proof frame.

Treatment of Gloxinias (G. R.)—The bulbs will now be going to rest. As soon as the foliage begins to decay, gradually withhold water. When the leaves turn yellow shake out the bulbs and store away all together in sand in a warm house or room until April, or if only a cool house is available a month later will be time enough to repot.

Convolvulus, destroying (Aurelius)—The only true way of doing this will be to keep the tops cut off with the hoe immediately after they make their appearance—indeed, if the ground is kept constantly hoed the shoots will have no chance of appearing above ground and the roots will then in time die from the want of that support they can only obtain from leaves and shoots.

Rambler Roses (E. D. Prichard)—The only thing you can do is to cut out all the old and useless wood, retaining all the growths made this year. Then give the plants a thorough soaking of water and in the coming spring apply a heavy mulch of rotten manure, keeping this thoroughly soaked, so as to wash the goodness of the manure down to the roots of the plants. If this fails to benefit the plants, then it would be advisable to grub them, clear away the old soil, and replace with good loam. Plant strong, healthy specimens as soon as you can procure them in the autumn.

FRUIT.

Pruning Black and Red Currant bushes (M. W.)—These can be pruned as soon as the leaves fall off in the autumn. With regard to the row of Red Currants that has become too thick, it would be advisable to dig up every other plant in the row, and thus give the necessary room to the remaining ones, duly thinning out their branches at pruning time. If the trees that are removed are young, thrifty ones, and they are lifted carefully, they may be replanted elsewhere, if required, but if they are old ones then burn them out of the way.

Summer pruning of fruit-trees (A.)—If you wish to practise summer pruning on the breastwood of your well-trained Pears, cut at once all those shoots back to about five leaf-buds. It is doubtful whether, done then, the point-bud will push growth; but if it does, then pinch that secondary shoot after two leaves have been formed. No growth will follow that; but the back buds, while seemingly dormant, will undergo partial change by becoming fruit-buds, but would need all the following season's growth to become perfect ones. In the winter cut every one of these spurs back to two buds only.

VEGETABLES.

Tomatoes on open walls (Grower)—After this date it is doubtful if Tomatoes on outside walls will derive further benefit from being allowed to remain any longer in that position, the only exceptions being those which can be covered with glass lights by day and some additional covering by night. We should not recommend their being removed if the weather keeps fine and mild, but chilly nights, heavy fogs, and very slight touches of frost, even if not sufficient to blacken the foliage in the least degree, are not conducive to ripening, and, except under the most favourable conditions, we advise that the plants be first cleared of all fruits which are colouring, also of those too small to be of use, and then cut bodily off and hung up in a dry, light house where there is not much draught, or laid on a shelf in similar quarters. Here the fruits will colour up and be useful for cooking for many weeks to come, but not, of course, of the quality required for salads. The fruits already colouring will ripen up and be useful for either purpose.

CLEARANCE SALE

Due to our Works and Show Grounds being taken over by the War Office, we are offering the remainder of our Stock unsold at Special Low Prices.

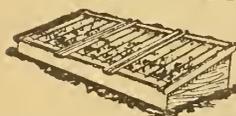

SEND FOR CATALOGUE. PORTABLE GREENHOUSES.

ROYAL HORTICULTURAL SOCIETY AND THE TEACHING AS TO PRUNING SHRUBS.

The number of flowering shrubs now in British gardens, both evergreen and summer-leaving, is so great that their treatment is of importance. A lecture on the subject has been given by Mr. E. Beckett, and we do not doubt that he is right as regards the general way of pruning shrubs in gardens, but the real question is the value of this treatment. There can be but one answer—ugliness and unnatural forms. Mr. Beckett again and again urges clipping the shrubs to a shape, and his idea of shape is not the natural or true form of the shrub. All round London—and, indeed, every city of England—there are examples of this false, inartistic treatment of shrubs naturally beautiful in form. There is hardly a shrub that escapes, from the Holly to the Rockspray. The round, lumpy form is that usually chosen in preference to the free, natural form.

HOLLY.—He tells us:—

"Most varieties of the Holly require some pruning to keep them shapely, and such pruning is best done about the middle of July."

Here we have a general idea of the way he would have us treat our most beautiful native evergreen. To suppose that by pruning we can get a better form than the natural form is an illusion. If anyone who considers these things will not accept the word of a nature-lover, let him ask the artist who has to deal with natural form for an opinion, and he will get only one answer. I have planted a few thousand Hollies and hope to plant more, and I would as soon allow an academy student to daub over a Fautin or a Corot as to attempt to improve the true form of a Holly-tree.

YEW.—Badly, however, as the Holly is treated by the advocates of pruning, the Yew is in much worse case in their hands. Again, to quote from the source above mentioned, at p. 33:

"Taxus baccata, the common Yew, as is generally known, responds splendidly to the knife, and may be cut to almost any shape required. Other varieties of this family may be pruned in as required."

This illustrates the unfortunate fact that the Yew-tree is mutilated out of all shape in gardens generally, and often, indeed, assuming fantastic and pantomimic shapes. Naturally a hungry forest tree, the Yew has no true place in the garden foreground at all, and if we put it there, we must cut it in to get it out of our way. The result of this mutilation is that to see the Yew in its true beauty is not easy except in a graveyard or here and there on the hills of Surrey or Kent. That is a great loss to us, because no conifer that comes to us from across the sea is more beautiful in form than the Yew.

Box.—Another native evergreen often grown in gardens, but usually pruned out of its natural form, is the Box. As confession is said to be good for the soul, I may say that after experience of the Box in many gardens, I never saw it in its full beauty until one day with Alfred Parsons, the landscape artist, I saw it on the hills where it grows on Box Hill. There I saw the plummy grace of the bush for the first time. To see the full beauty of this shrub we must let it alone, and not prune.

ELÆAGNUS.—Among the evergreens which are naturally charming in the winter, the Elæagnus is often the object of this disfiguration. If it is clipped into a mop-headed thing, we cannot see the silvery charm of the leaves when moved by the wind. Our land, more than any country in Europe, is rich in evergreens, and it should be the aim of the gardener to preserve their natural forms and not destroy them.

THE EVERGREEN CHERRY is among the shrubs which are disfigured by this false idea of pruning. There are acres of such plants round every suburb. The last time I was at Cliveden there were large areas of it under beautiful trees, all clipped to a hard line. In the county in which I write there is a garden set out with Portugal "Laurels" all on legs, which is not their natural habit, and with their heads all clipped in like a jail-bird's hair. This is one of the best of our beautiful evergreens, but never if out of its true form. The true Laurel—in our country called the

Bay—one often sees clipped in tubs, but its true beauty is never seen except with its natural toss and growth. It is quite hardy over a large area of our southern country, and there is no reason at all for distorting it.

LABOUR.—Consider only the question of labour. A garden full of such shrubs makes a heavy demand on labour, which is wasted in doing harm. The gardener has much work to do, and we ought to get the best out of him, but if months of his time are wasted in disfiguring beautiful things how can he attend to his true work?

More perhaps than any country of western Europe, these islands can grow beautiful evergreen shrubs. There are the Azalcas of Japan, the evergreen shrubs of California, and the fine evergreens of New Zealand, which charm us by their grace and freshness in winter. The Camellias are hardy over a large part of England and Ireland, and some of them are distinct and beautiful, although we have hardly touched as yet the best of them—that is, the bold single ones. Rhododendrons and Azaleas we have everywhere, and these take their own beautiful forms, and any attempt to make them take a boiled-pudding shape is fools' work. So with the Mountain Laurel (Kalmia), which is a lovely shrub. What we have now of these precious shrubs are not all that we shall have in the future, because many of the plants of those countries have not yet been introduced.

A serious consideration of this distortion is the effect on children and young gardeners, who get the idea from it that it is the right thing. Its effect on artists who love to see the play of light and shade and true form is repulsive. Mr. Mark Fisher, one of our best landscape painters, told me that when he was seeking a place in some quiet county to work in, he would not settle near any town because the hard look about most gentlemen's places, with their rigid lines, distorted forms, iron fences, gardens like bad carpets, made his work impossible, and so he went where the farmers have no time for such distortions. Any stereotyped way of this sort is difficult to get rid of, and even educated

people get possessed by it. There is no place where the practice can be seen more in evidence than in the drives to many country places. At Eastnor, when I was there, there was a dead dark line all along the drive, here and there blocking out beautiful views. It is not always done by design, because the men do it mechanically when trimming drives. The right thing is to tell them where to cut out so as to get back to a natural line.

Our country places often have beautiful landscape around them, and it is well that a foreground should not be disfigured by things false in form. The cutting of box and yew to form tracery gardens is another example of the evil work, as one sees at such gardens as Minley and Crewe Hall.

SHELTER.—Where our native or other evergreens are used for shelter, it is more than important that they should not be cut into hard lines. Where as at Abbotsbury, Batsford, and many other places, evergreens are used for shelter, it is better they should take their natural forms, which will sift and soften the storm better than any wall-like lines. If evergreens are put into wrong places at first, they must be cut out or cut in. The evil is partly caused by gardens being laid out by men who know nothing of the true size of things they plant, so that we see trees taking gouty growths and DISEASED forms, as we see in many streets in South London now and in French towns.

As to beauty, no grace of Parthenon marble, Rembrandt tree, or Corot landscape, can even suggest the charm of our native evergreen when tossed by the winds that play for ever over our islands.

NOTES OF THE WEEK.

Colchicum Bornmulleri.—The large, handsome flowers of this species, now brightening up the rock garden, look almost like Tulips instead of Crocus. My plants are very happy in a rather poor and very limy soil, and increase each year.—W. O.

The Shamrock Pea (*Parochetus communis*).—This usually begins to flower here about the middle of June; occasionally in May. On October 1st there were only two flowers. Two days later there were at least a hundred.—E. CHARLES BUXTON, *Coed-Derw, Bettws-y-Coed.*

Erinacea pungens, hardiness of.—The question of the hardiness of this distinct and attractive plant is raised in the note accompanying the excellent illustration on page 477. The plant is one of some importance. I have not seen it doing well in the south-west of Scotland, where the wet winters are apparently obnoxious to it, but in the east, south of the Tay, I have observed it doing well after having been planted for several years and left unprotected in winter.—S. ARNOTT.

Double-flowered perennial Asters.—It may be remembered that last year there were complaints that the new varieties of double-flowered Michaelmas Daisies were not fixed, and, as a fact, they were to a great extent disappointing. At the time, I expressed the opinion that the heat and drought were responsible for this reversion to the single forms, and I am confirmed in this belief by their appearance

at the present time. I see that the great majority of the flowers is opening double. We have, of course, to remember that these double varieties are in their infancy, and a certain amount of time must elapse before the tendency to reversion is completely eradicated.—J. CORNHILL.

Phyteuma Scheuzeri.—Most of the members of this family seem to be easy doers and free bloomers. Though not particularly striking, this species is useful for the rock garden, and has been full of its quaint blue flowers this year. There seems to be a good deal of similarity between the various species, but they are interesting and good for a small pocket in a sunny situation, where they are quite content to grow happily without intruding on their neighbours. Our native *P. orbiculare* is found on chalk downs, and the subject of this note also appreciates lime. It ripens plenty of seed, from which it is easily increased.—N. L.

The Whorl-flower (*Morina longifolia*).—Some seedlings of this are now (September 22) flowering well. The pink and white blooms in whorls along a stem over 2 feet in height are very pretty, and, I think, more appreciated at this time than those of older plants earlier in the season. The spiny Thistle-like foliage of the *Morina* gives off rather a pungent odour when bruised, although by some people that odour is appreciated. *M. longifolia* succeeds in any ordinary garden soil, and is not fastidious in respect of position. Here it does equally well in the somewhat light soil of a south border and in a more retentive situation facing the west. Self-sown seedlings are freely produced.—W. McG., *Balmae.*

Abelia grandiflora.—This is, perhaps, the best of the *Abelias* for general cultivation, for not only is it fairly hardy, but it is a good evergreen and flowers freely. It is of hybrid origin, its parents being the two Chinese species *A. chinensis* and *A. uniflora*. In gardens it may be grown in the south of England as a bush in the open or as a wall plant, whilst in numerous other places it can be grown successfully against walls. Growing 5 feet or 6 feet high, it forms a rather dense bush. The flowers, tubular, white, flushed with pink, are borne in large clusters from the ends of the shoots and from the upper leaf-axils, interspersed with leaf-like bracts, the flowering time lasting from July until the advent of frost or until late October. It grows well in soil that is warm and well drained. Regular pruning is unnecessary, and it is a mistake to prune wall-grown plants too severely. Rather fix the main branches to the wall so that the secondary shoots may develop freely. Cuttings inserted in light soil in a close frame in summer root quickly. In addition to the uses already mentioned it is also a valuable shrub for large pots or tubs, for standing on terraces during summer.—D.

Striking Calceolaria cuttings.—I was much surprised to read in the issue for September 9th that Mr. Gallop had been having *Calceolaria* cuttings put in the previous week. In my young days I was taught—and most gardeners teach the same to-day—that from the beginning to the middle of October is the ideal time for inserting *Calceolaria* cuttings. The first week I have chosen for some years. *Calceolarias* should not be encouraged to make roots and fresh foliage before winter sets in, which they will do when put in so early. All that is necessary is to get the cuttings callused over by the winter, and then they start away strongly in the New Year. Another plant, cuttings of which writers sometimes advise striking in gentle

heat, is the double white *Marguerite Mrs. Sanders*. The cuttings of this plant will strike far better if put into cold frames like the *Pentstemon*. True, they may take a little longer, but the result is better, being hardier and much less liable to attacks of green fly and maggot.—C. TURNER.

Tropæolum polyphyllum.—Complaints are sometimes made as to the shy blooming of this species, but in a general way the grower has himself to blame when flowers are scarce. In nine cases out of ten he has been too kind, there has been too much food, and the plants have run away to leaf instead of bloom. When this is the case plant in the most elevated, sun-baked position in the garden, in a rooting medium consisting of loam one half, with stones, mortar-rubble, or crushed brick. In this material the growth will be short and stout, and the shoots will be crowded with bloom. This *Tropæolum* is a valuable plant for poor, stony soils, which become very dry and parched in summer, but is quite out of place and disappointing when good culture is given.—J. C. B.

Kniphofia aloides.—During September the Torch Lilies are a feature of these gardens, the clumps being of considerable age and size, and annually bearing large quantities of spikes. Although, perhaps, not quite so numerous this year as is generally the case, yet the display is very fine. On one clump the number of perfect heads is eighty-seven, there being many with between fifty and sixty, with but few under the half-hundred. The effect of these at a little distance can be imagined. The *Kniphofias* are apt to exhaust the soil rather quickly, so that if the display is to be annually maintained a good allowance of liquid-manure must be given during the period of growth. During the present season much benefit has resulted from occasional applications of a fertiliser, which was well watered in.—W. McG., *Balmae, Kirkeudbright.*

Crinums.—One wonders why, in his note on these at page 468, "W. McG." cites "*C. capense* and *C. Moorei* as the best forms for outdoor cultivation" to the exclusion of *C. Powellii* and its varieties, which without doubt are the best for the purpose indicated. By comparison the first named is very inferior as regards beauty and vigour, though interesting enough to be included in a set of these plants. The great shafts produced by the *Powellii* varieties, towering often enough to 4 feet high, render them invaluable where such plants are grown, the warm rose tints of the typical kind, together with *blandum* and *intermedium*, having no parallel in the others named. They are hardy, too, hardier generally, so to speak, than *C. Moorei* and its white variety, though not quite equal to these in flower quality. Near the sea they are usually hardy enough in the open border. Further inland they are best given the protection of a dwelling or greenhouse wall, and with a depth of 2 feet or 3 feet of good soil to root into will surprise by their vigour and the imposing array of flowers. In any planting, however, I would keep the *Powellii* varieties apart. *C. capense* is dwarfier and should be seen alone.—E. H. JENKINS.

Pentstemon isophyllus.—Those who have not hitherto grown this graceful Mexican species should lose no time in making its acquaintance. As elegant as any of its race—not even excluding the very desirable *P. barbatus*—it is good enough for all who grow the best of hardy plants. It is alike good, too, and apparently equally happy given a medium or light, sandy soil to root into in rock

garden or border, in either of which its sheaves of elegantly-disposed flowers would be sure to attract attention. It has the merit, too, of complete hardiness so far as southern gardens are concerned, and, even if a little tender elsewhere, is so good and distinct—not to say free-flowering—as to be worth the trouble of striking a few cuttings each year to perpetuate youthful stock. Three feet or so high when fully grown, it forms a bush at three years old almost as much through, a group when in a good position being very telling. The flowers are somewhat tubular and have a scarlet exterior, the throat lighter and whitened to some extent. It has been grown in the open at Kew for some years with success, but is probably far from being in general cultivation, which it certainly merits.—E. H. JENKINS.

Paris Daisies (*Chrysanthemum frutescens*).—The interesting article on these (page 424) reminds one of the prominent position they now occupy in many gardens.

PLANTS AND FLOWERS.

ROCK, ALPINE, BOG, FERN, AND WATER GARDENS.

GENTIANA ACAULIS.

As the season is at hand when this can be planted with hopes of success a word or two to those who have had difficulties with it may be helpful. One frequently hears amateurs say that, while they can grow *G. acaulis* into large clumps, they cannot induce it to flower satisfactorily. This, I believe, is largely a matter of soil and aspect. If the soil is inclined to be stiff and cold, or too rich, the plant may flourish, but blooms will be few. And, as to situation, this should be fully exposed to the noonday sun and not subject to the drip from trees or eaves. I have some large clumps of *G. acaulis* that thrive and blossom abundantly not only every spring, but often in the autumn as well, and they

pear and increase in number with each successive spring. The above suggestions apply equally well to *G. verna*.

North Wales.

A. T. JOHNSON.

COBWEB HOUSELEEKES IN POTS.

Those whose gardens are of limited extent will do well to keep in mind this remarkable section of Houseleeks, and grow them in pots, a method of cultivation for which they are eminently suited. Better still is it, where the aim of the grower is, as it should be, to bring out the best a plant is capable of giving, to grow them in fairly large pots or those half pots now the vogue for dwarf-growing subjects in the alpine-house. For the dwarfiest alpine vegetation there is a sense of proportion about these latter quite alien to pots of ordinary depth. These, indeed, to me appear out of scale—all pots and little plant, as it were. Perfectly drained pots, 6 inches or 7 inches across, filled to the brim with gritty loam, with which has been mixed plenty of old mortar rubbish, will suit them well, the single rosettes of the Houseleeks to be pricked out an inch apart over the whole area. With a season's growth, the surface of the pot will be covered, the cobweb effect being much enhanced when the pots are placed on a sunny window-ledge or like place too hot for ordinary things to succeed. On level ground and on rock-work in wrongly selected positions the effect is less pronounced, hence the window-ledge renders a dual service by bringing out what is best and maintaining it. Some plants so treated a year or two ago have remained effective since, and, moreover, are interesting in winter as well as in summer. Among many varieties, I find one I have as Hookeri to possess the whitest web, though *Sempervivum arachnoideum*, *S. a. rubrum*, *S. tomentosum*, and *S. Laggeri Housei* (the last very fine, but quite rare, I believe), may be accounted as indispensable.

E. H. JENKINS.

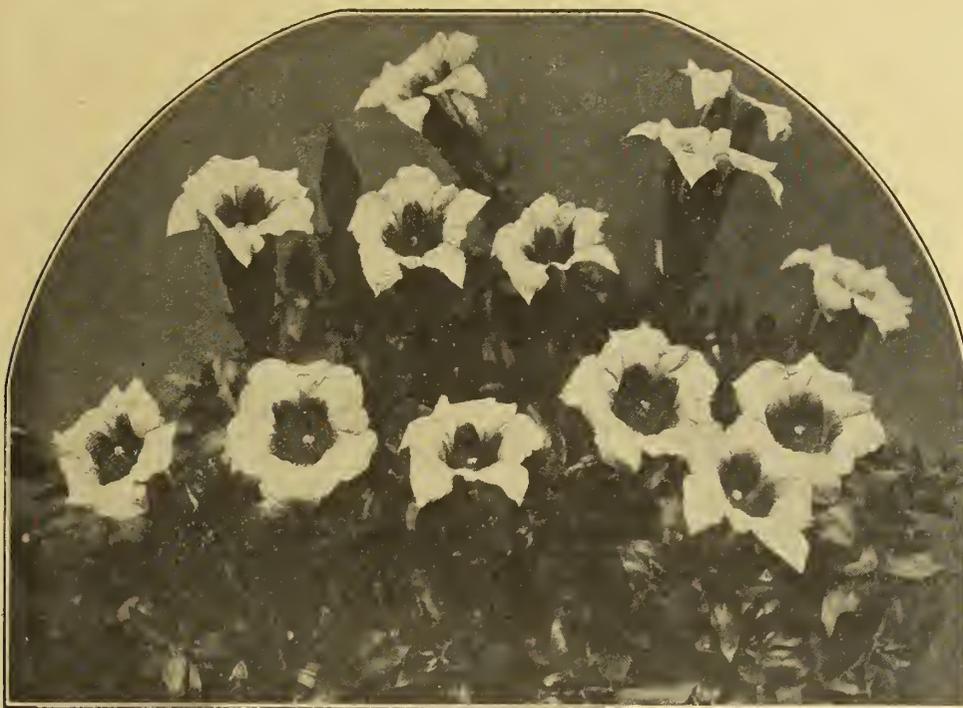

NOTES AND REPLIES.

The pale Toad-flax (*Linaria repens*).—This spreads very fast, its roots running about underground and coming up all over the place. For a rough bit of rockwork, or associated with other strong-growing things, it is valuable, as in the autumn it becomes a mass of little lilac "Snapdragon" flowers, borne on slender stems, and is very pretty. Many people will have nothing to do with it because of its aggressive habits, and unless one has lots of room, it is perhaps best avoided, but it is so charming when in bloom that if a good space can be allotted to it away from choicer subjects, it is well worth growing. There is a pure white variety, which is not quite so vigorous.—W. O.

Morisia hypogæa.—Considering the ease with which this species can be propagated, it seems surprising that it is not cheaper than it is. Nurserymen who price many of their alpine plants at 6d. or 4d. each, ask 1s. for this species. I put a dozen cuttings into pure sand in a frame in July, and every one rooted. It seems somewhat of a capricious species in some districts, as several of my friends tell me they find it difficult to grow.—N. L.

Potentilla nitida.—This has been very pretty in the rock garden during August, with its soft silvery foliage and charming little flowers of pink or white. I grow it in very gritty, limy soil in full sun, and it flowers freely, the soil being rather poor. It is quite one of the best of the rock *Potentillas*.—W. O.

Geranium Wallichianum.—This is still covered with flowers, those of Buxton's variety being the better, of a lovely deep blue shade. It is quite easy to grow in light, limy soil in a very shady place, and does very well in a retaining wall, where it spreads freely.—N. L.

Gentiana acaulis. From a photograph sent by Mr. A. T. Johnson, Ro Wen, Tal-y-Cafu, N. Wales.

They have long been favourites with the market grower, and enormous quantities are disposed of in Covent Garden during the season. The first one to market the flowers was the late Mr. Hermann Herbst, of Richmond. He obtained some plants of the typical *Chrysanthemum frutescens* quite early in the 70's of the last century, and grew them into large specimens. They flowered almost continuously, and when taken to Covent Garden Market the blossoms sold well. So remunerative a crop did these Marguerites prove that from occupying a small portion of a large Camellia-house they in time ousted the Camellias. Mr. Herbst never attempted to grow plants of this *Chrysanthemum* for sale, but as cut flowers they were for some years much appreciated. The typical *C. frutescens* cannot be cut with long stalks, but in those days practically all cut flowers were wired, so that was not so much a drawback as it would be now. Some of the present-day varieties have longer stems, and of these the double-flowered Mrs. F. Sander is particularly useful for cutting.—W. T.

are growing in the poor, shaley loam of a southern slope. The drainage is as good as can be at all seasons. No top-dressing or other attention—beyond, perhaps, a good dose of water occasionally in very dry weather—is given them, and there is no lime in the soil. Yet the results are, as I have stated, most satisfactory.

PROPAGATION.—It is a mistake to increase by lifting established plants and dividing them up, for they resent interference, and, after all, we can hardly have the clumps of so slow a grower too large. It is a quite simple matter to propagate at this time of year by offsets. These will usually be found round the margins of the clumps, and if they are carefully removed a few roots will usually be found attached to each. Plant these in a sunny pocket of stone chips, old mortar, a little mould, and plenty of sand, and they will rarely fail to prosper. The material should be well rammed down and the plant pressed firmly in. Blooms should not be expected the first year, but after that the wonderful dark blue trumpets with their iridescent throats of peacock-green will begin to ap-

CHRYSANTHEMUMS.

EARLY-FLOWERING CHRYSANTHEMUMS: DISBUDED OUTDOOR VARIETIES.

THERE has been a growing desire in more recent years to emulate the practice of a few of the larger market Chrysanthemum growers by cultivating a limited number of really first-class sorts on the disbudded principle. The plants are grown on until the time arrives for them to break out into branching growths. At this period, on those plants which it is intended shall produce about a dozen fairly large blooms of good quality, three or four good shoots are allowed to develop, these, in turn, each producing about three other shoots. From the four shoots first taken up, a dozen good, sturdy growths are developed. These same shoots are securely staked. One good, plump bud is retained at the apex of each shoot so soon as developed, and when the whole of the buds are secured the plants are carefully watered with occasional doses of weak liquid manure. Buds of this kind are developing very satisfactorily just now. Very handsome blooms are produced by this method of culture. I know of no other method that produces such splendid results with a minimum of trouble. Varieties that are doing well under this system of culture just now are the following:—Almirante (chestnut-crimson and gold), Cranford Yellow, Framfield Early White, Cranford Pink, Cranfordia (one of the largest and best yellows for October), Juliet (rosy-red and cinnamon), Mrs. Scott (white), Pink Princess, Crimson King, Mrs. Roots (a pretty incurved Japanese white dwarf), Phoebe (soft pink), Dolores (bronzy-terra-cotta), Golden Glow (canary-yellow), Hector (mauve-pink), J. Bannister (lemon-yellow, shaded copper), Perle Chatillionaise (creamy-white, shaded rosy-peach), Nina Blick (bronzy-crimson), Kathleen Thompson (chestnut), Caprice du Printemps (deep rosy-pink), Soleil d'Octobre (yellow), and Bronze Soleil d'Octobre. W. V. T.

CHRYSANTHEMUMS—WORK AMONG.

DURING the week top-dressing was completed. As has been previously indicated, almost all of these are grown in bush form, and up till now growth has been well maintained. For top-dressing, some good old loam with which was incorporated a little fertiliser, together with a small proportion of soot, was used. This will give a fillip to the plants and carry them on to the housing period without any further stimulant. Earwigs have been giving a little trouble, and these are being sought for, trapped, and destroyed. It is a curious fact that these pests are much more numerous in some seasons than in others. Watering is now attended to every day, whether bright or otherwise, as there is always a plant or two which may need moisture. The foliage is well hosed late in the afternoon when the sun has been strong. In a general way housing is practised about the 26th of September. Exhibitors find this date very suitable for the development of blooms for the early November shows, but with the leading Scottish show this year put off, if the weather remains open there is no pressing need to house the plants until early a October. Border Chrysanthemums are turning in at their correct time. It is, at times, aggravating to have these useful plants in full bloom at the end of August, but here, at all events, it was well into the third week of September before the display (except, of course, in the case of the

very early varieties) was general. Time ought to be spared to secure the heavily-budded shoots to the stakes, otherwise damage is sure to follow from heavy showers, the shoots being very brittle. Where possible to do so without unduly interfering with the plants, an occasional run through with the hoe is of service.

KIRK.

NOTES AND REPLIES.

Over-feeding Chrysanthemums.—There is a lot of sound advice given in the note on the above subject in GARDENING ILLUSTRATED, page 479, issue September 23rd. I lately paid a visit to a gardener who has this year grown exceptionally fine plants without the aid of any feeding or stimulating foods. He has not a single deformed bud. In past years he has grown many plants for the production of exhibition blooms, feeding very freely, and suffering much loss through bad buds. He thinks that over-feeding was the cause. Personally, I never did feed my own plants, and did not lose buds, nor blooms through damping, to any serious extent. Plants to bear blooms in December and at Christmas require less feeding.—G. G. B.

Early single Chrysanthemum Formidable.—This is an excellent early Chrysanthemum. The flowers, of moderate size, are crimson, with yellow centre. Much of its value lies in its sturdy stems, which make the flowers all the more valuable for cutting.—S. A.

OUTDOOR PLANTS.

CLEMATIS DISEASE.

IN M. Morel's letter on this subject, which appeared in the issue of September 23rd (p. 475), there are apparently one or two errors. M. Morel is made to say "A moment ou l'ouvait une plante flétrir," which, as far as I can see, has no significance. Evidently "l'ouvait" should be "l'on voit," that is to say, as soon as one sees a plant flag. On column 2 à peu près should surely be à peu près, meaning that the Viticella type is almost immune from disease. M. Morel appears to regard any attempt to combat the disease as hopeless, and is trusting solely to raising a new disease-proof race. He is relying on selection instead of hybridisation, and is, in his own words, trying to "enrich the colours and increase the size of the blooms without having recourse to C. patens and C. lauginosa." Working over a number of years, he has "formed a collection of fine, hardy varieties." Such a race of Clematis immune from the disease, which in some places renders the culture of this beautiful flower very uncertain and sometimes impossible, will undoubtedly be very valuable. M. Morel condemns the use of C. Vitalba as a stock for the big-flowered varieties, and I can well believe that many failures are due to the fact that our native species, vigorous and enduring though it may be when in natural conditions, is not happy in the majority of gardens. There are some native plants which flourish in any kind of soil, but there are others which will only live indefinitely under certain conditions. In my experience the Traveller's Joy is only found growing naturally on a chalk sub-soil, and the nearer the chalk to the surface the more luxuriant does it grow. Some ten miles from where I live it garlands the hedgerows, and the chalk comes within measurable distance of the surface. Although it was probably growing there when the pilgrims wended their way to Canterbury, it has never shown the least inclination to spread, and in an area of at least seven miles, although old hedgerows similar to those in which it grows so luxuriantly abound, I have never seen one single plant. So far as I am aware not a particle of chalk is to be found in that

area, the sub-soil is clay or gravel, frequently both.

As is well known, seeds are carried by the wind and birds, and young plants appear far removed from the parent plant. Why is it that this Clematis has obstinately refused to extend in the same manner? During all that time countless seeds must have been distributed by the same agencies. Have none of them germinated, or, finding conditions not to their liking, have the seedlings refused to take possession? Some years ago, on some clover being cut, numerous plants of Echinum vulgare and many Cornflowers appeared and bloomed freely. Neither of these plants is found growing naturally with us, but both are found where C. Vitalba grows, the seeds coming, undoubtedly, in the clover seeds, which were presumably harvested on the chalk. Innumerable seeds must have been formed, but the following year only a very few plants appeared, and after that none. The great demand for C. Jackmani and other varieties caused trade growers to seek for a quick and easy method of propagation, and they selected C. Vitalba as a stock, never giving a thought to the fact that it was not likely to be happy in the majority of soils. In the heyday of youth, and planted in well-enriched, freshly-stirred ground, the influence of this stock is often not much felt, but with age, and when so smothered with bloom that there is a heavy call on the nutritive functions, the malign influence of an unsuitable rooting medium makes itself felt and induces a certain amount of debility.

M. Morel has a good opinion of C. Viticella as a stock. Has he, I wonder, ever tried C. Viticella rubra grandiflora, which I take to be the most vigorous and reliable Clematis in existence? It flourishes in any soil and situation, is a very rapid grower, and, so far as I am aware, is free from disease. J. CORNHILL.

Byfleet, Surrey.

TUBEROUS BEGONIAS IN THE GARDEN.

I THINK "Kirk" (page 452) rather underestimates the value of tuberous Begonias for the flower garden, or they have received scant attention in some of the gardens he noticed, as given a little care there are few things among tender plants that give a brighter or more enduring display. They look quite gay after weather that will practically spoil things like Pelargoniums, Heliotropes, and Lobelias. They want a little extra attention in the way of soil—that is, a fairly liberal supply of very short manure if the ground is poor, and broken horse-droppings or leaf-soil if naturally heavy. As frequently recommended in GARDENING ILLUSTRATED, it is much better to plant varieties with erect flowers than those with extra large, drooping blooms, which are broken down with the first high wind or heavy rain unless considerable time can be spent in staking and tying. I saw a cottage flower garden the other day in which they were doing remarkably well. The owner winters his tubers in a cold frame, where he leaves the plants until he thinks it safe to transfer to the open ground. He is very proud of his plants and remarked that "They are a bit of extra trouble because it is no use sticking them in anyhow." Apart from the distinction between erect and drooping flowers, there are, of course, some varieties that adapt themselves much better than others to outside planting. As a rule, the scarlet and pink shades are the best, and the whites and yellows—especially the latter—the least satisfactory. A yellow known as Golden Ball was planted rather extensively in the

old "bedding-out" days. It was a heavy, finely-shaped flower, very satisfactory under glass, but decidedly too heavy for the outside. A rather better type for the outside was that represented by a variety known, I think, as Canary Bird, a small, very even flower. E. B. S.

Hardwick.

NOTES AND REPLIES.

Crocus candidus.—Few of us will not own to an ardent admiration for the glowing flowers of the Crocus, which in spring and in autumn make our gardens so bright. I add autumn advisedly, although, unfortunately, the autumnal Crocuses are not so well known as they ought to be. We might well add a greater variety even to our Crocuses of spring, and instead of contenting ourselves with the glorious Golden Yellow one and the Dutch varieties of *C. vernus*, unsurpassable though they are, we may wander a little into the bye-ways of Crocus cultivation and include in our gardens such flowers as those of some of the other species. That named *C. candidus* is one of these, and is a lovely little Crocus with white flowers in the interior and either wholly white on the outside of the segments or streaked or suffused with pale purple. It is not a common species, but is a very beautiful one and thrives with the same treatment as the common spring Crocuses. It flowers in March, as a rule, its charming white flowers all the more attractive by the orange anthers. Corms should be planted an inch deep in dryish soil in a sunny place.—S. ARNOTT.

The Kaffir Lily (*Schizostylis coccinea*).—Already (September 22nd) stray spikes of the Kaffir Lily begin to be noticed. Generally speaking, these are usually looked for a month after this time, the display lasting on throughout November. These are planted in a warm south border and increase rapidly, their vivid scarlet spikes, resembling to some extent miniature Gladioli, being very welcome in the dull days. *S. coccinea* makes an excellent cool-greenhouse plant, good pieces in 8-inch pots being very useful.—KIRK.

Birds and yellow Crocuses.—Much has been written as to what induces birds to destroy certain flowers, such as the ordinary yellow Crocus. Sparrows receive a good deal of blame for the destruction of these flowers, but they are not by any means the sole offenders. Some of the finches are very troublesome, and a great source of trouble in many places is the pheasant. I know a number of places where the purple and white Crocuses—varieties of *C. vernus*—are in millions and have been for many years, whereas there is not a yellow Crocus to be seen. This is caused by the pheasants, which are very destructive. They not only destroy the flowers, but also the bulbs, which they uproot and devour.—S. A.

Geranium sanguineum album.—The colour of the type is not a very pleasing one, but the white variety is a lovely plant for the rock garden and quite easy to grow, though perhaps not so vigorous as the type, as often seems to be the case with albino forms. *G. s. lancastriense*, too, is a beautiful form, its large, pale-pink blossoms, with deeper coloured veins, always pleasing. Both flower over a long period, and as they ripen plenty of seed are easily increased. A sandy soil in a sunny position suits them well.—W. O.

The yellow Fumitory (*Corydalis lutea*).—Though one of the commonest, I think this is one of the most beautiful of its family and indispensable for a shady retaining wall. It makes a big round clump of lovely green Maiden-hair-like foliage, and bears freely its clear, deep-yellow flowers in September and October. It seeds freely with me.—N. L.

The double Soapwort.—This is a valuable plant for autumn bloom, coming in at a time when other border perennials of its colour (rose) are scarce. It has a troublesome

habit of running at the roots, and has a tendency to spread over a border and of coming up here and there among other plants, a fault not always easily condoned.—S. ARNOTT.

YUCCA WHIPPLEI.

THE accompanying illustration of *Yucca Whipplei* directs attention to a very beautiful species which, unfortunately, is only hardy enough to succeed out of doors

Yucca Whipplei, in Messrs. R. Veitch and Sons' nursery at Exeter.

in the milder parts of the country. A native of California, it was first brought to notice in this country when a figure appeared in the "Botanical Magazine," t. 7662, in 1899. The plant from which the drawing was made was grown in the garden of Commendatore Hanbury at Ventimiglia, where it flowered in 1891. When not in bloom it appears as a dwarf plant with a prostrate or semi-prostrate stem and narrow, rather stiff, glaucous-green

leaves up to 20 inches or so long and scarcely $\frac{1}{2}$ inch wide. On the approach of flowering, however, it quite alters its appearance, for it produces an erect, stately inflorescence between 4 feet and 12 feet high, the upper half clothed with pretty cream-coloured flowers, each one 2 inches to 2 $\frac{1}{2}$ inches in diameter. A good idea of the beauty of the inflorescence may be gleaned from the accompanying illustration of a plant that flowered in Messrs. Veitch's nursery at Exeter. For the south-west counties and the Scilly and Channel Islands it is a plant well worthy of consideration, while it may also thrive in warm localities elsewhere. D.

GARDEN PESTS AND FRIENDS.

NOTES AND REPLIES.

Celery, fungus on.—I should be much obliged if you could tell me what is the matter with the enclosed Celery leaves, and whether there is any remedy.

[Your Celery has been attacked by the Celery-leaf-spot fungus, which has during the past few years caused much loss to growers. The fungus causes the leaves to wither and rot away, after which the stems decay, and finally the whole of the plant disappears. As the spores of the fungus infect the soil for some time afterwards, Celery should not be grown on the same plot of ground for several years to come. There is a possibility of arresting and finally subduing the attack if you spray the leaves at once with Bordeaux mixture, but if the whole of the leaves are in the same condition as those of the sample sent, spraying will be of no avail. After the Celery has been dug, give the soil a good dressing of quicklime, or disinfect it with one of the soil fumigants which are so frequently advertised in the pages of this journal. If next year you see any signs of the fungus, spray lightly with Bordeaux mixture, which any horticultural sundriesman can supply you with.]

Caterpillars injuring cuttings.—I enclose specimens of some grubs which I found recently attacking flower and shrub cuttings, also plants in the open garden. Will you kindly tell me its name and the best means of exterminating it or clearing it as far as possible?—Wm. C. IVES.

[The grubs you send are the larvæ of a Noctuid, which becomes fully fed in the autumn, produces a chestnut chrysalid in the soil, and emerges as a moth in late June or July. The best treatment for all caterpillars, where hand-picking is impossible, is spraying with Paris green or lead arsenate, unless the plants attacked are to be used as food. In some cases the pests may be captured by making a hole in the ground with a round piece of wood and placing a piece of some attractive bait, such as Lettuce-leaves, near or over the hole. Many of these Noctuids delight to hide during daylight, and the hole provides shelter, from which they may be extracted and killed by the usual pressure methods or by dropping into hot water.]

Antirrhinums, fungus on.—Would you please let me know the cause of the spots on the leaves and stems of the enclosed Antirrhinum? I have given the plants the same treatment for years, and this is the first time they failed.—J. McB.

[Your plants have been attacked by the fungus known as *Septoria antirrhini*. This disease spreads very rapidly when it once attacks the plants, and it is well to pull up and burn all the infected plants. Those not attacked may be syriaged with Bordeaux mixture or sulphide of potassium (fiver of sulphur) at the rate of $\frac{1}{2}$ oz. to a gallon of water. Do not plant any Antirrhinums in the place in which diseased plants have been growing.]

VEGETABLES.

VEGETABLES ALL THE YEAR ROUND.

I HAVE been a gardener now for eighteen months, with medium success. Could you give an article in GARDENING ILLUSTRATED on how to procure a good and varied supply of common vegetables all the year round in this bleak northern county? The gardening papers seem to cater for the south and favoured districts. April, May, and June were my difficult months. We had nine weeks snow and slush, and hail-storms from February to April this year. I have half an acre, seven people to provide vegetables for, and three hours per day to work in the garden. Can it be done?—WOMAN GARDENER, *Co. Durham.*

[There should be no difficulty in keeping up a regular supply of ordinary vegetables if those named by you in your other query can be grown. Naturally, the time and dates mentioned for the sowing and planting of crops in the south are not applicable to the county of Durham, but with regard to the crops usually raised in the former in autumn, such as Cabbage for spring cutting, Onions for spring and summer use, Spinach, Lettuces, and Turnips, the dates would be none too early, if early enough. Broccoli, we can imagine, would be a precarious crop with you, especially varieties which in more favoured localities turn in from the end of the year till the end of March. We therefore advise that the growing of these be omitted, but it would be worth while trying the late varieties, such as Model, Late Queen, Reading Giant, and Leamington, to see if they would not succeed, raising the plants early in May and planting at the end of June or early in July. The autumn varieties, such as Michaelmas White, Christmas White, Winter Mammoth, and Autumn Protecting, should do well with you. Raise the plants in April. Sprouting Broccoli, which is hardy and yields a great quantity of sprouts over a long period, should also be raised about the same time. Then there are the various kinds of Borecole or Kale of which the Tall and Dwarf Curled, Cottager's, and Scotch are very hardy and profitable, supplying a long succession of greens and sprouts from Christmas till April, and often later than this. Savoys, again, can be had over a long season by growing Dwarf Curled, Best of All, Drumhead, and Late Drumhead, sowing the seed of the first two in April and in May of the other two. Of Cabbages for summer and autumn cutting sow in April and May, two good kinds being Nonpareil and Enfield Market. A useful kind of Cabbage for autumn and early winter use is Rosette Colewort. From a May and June sowing, heads for cutting can be had from September, or earlier, till the end of the year. The plants can be set out 1 foot apart each way. For spring cutting Early April, Ellam's Early, and Flower of Spring should be suitable kinds to grow. Raise the plants in autumn, sowing not later than July 28th, and set them out as soon as ready. If you have not sown, obtain plants instead, and set them out 15 inches to 18 inches apart without further delay. Cauliflowers for early cutting must be protected with a frame during the winter. In this case seed must be sown about the middle of August, and the plants, when large enough, pricked off into the frame 4 inches to 5 inches apart and grown as hardy as possible. If this is impracticable you will have to rely on the April sowing, selecting varieties such as Early London, Walcheren, Magnum Bonum, and Autumn Giant, which will form a succession if planted as named.

Coming to Onions, those required for

spring, summer, and autumn requirements should be raised in autumn, sowing the seed about the second week in August. There would be a slight gain in point of time, *i.e.*, if Onions were required as soon as they can be had in late spring, if the plants are thinned to 6 inches apart in the drills in February or March next instead of drawing and transplanting the whole lot elsewhere. The thinnings in this case would, of course, be transplanted to about 9 inches apart to form a succession. The latter crop, if properly harvested, would keep up the supply till near the end of the year. Two first-rate sorts are Giant Lemon Rocca and Leviathan. If unable to sow in spring before April we think the better way would be to raise the requisite quantity of plants in autumn, sowing the seed at the same time as the foregoing and transplanting them in spring. Three good varieties are Ailsa Craig, Trebons, and Crauston's Excelsior. Not only would larger bulbs result, but they would mature in advance of spring-raised examples, a consideration, seeing your garden lies so far north.

ROOT CROPS, such as Carrots and Beet, should succeed if sown at the usual time. Parsnips should also do well if sown as early as weather conditions permit. Short-horn Carrots may be sown at three periods, *i.e.*, in April as early as circumstances allow, again in June, and towards the end of July. The bed in the latter case, if covered with litter during hard weather, can be drawn from throughout the winter. Turnips may be sown at intervals, varying the sowings according to the demand, from the middle of April till near the end of August. If the plants from the last sowing do not form serviceable roots they will, if left on the ground, yield a great quantity of tops or greens in spring. Hardy White and Brown Cos Lettuce raised from seed sown the third week in August would furnish a quantity of plants for planting at the foot of walls and in sheltered places in September. These would be ready for use in May. The plants not required could remain in the drills and be transplanted in spring. Another sowing made in September would furnish a succession. In spring sow as early as you can in April and at intervals till the first week in August. For winter use the July and August raised plants would have to be wintered in frames or pits. The best variety of Spinach for winter in your latitude would be the perpetual or Spinach Beet. This is very hardy and yields great quantities of leaves. Make a good sowing in July, another in August, and a final in early September. These three sowings would furnish a supply lasting from September till April and May. For summer use sow one of the smooth-leaved kinds from April till June, and the prickly-leaved sorts from then till the end of July. Vegetable Marrows you could raise under glass, or, failing the latter, under a hand-light on the bed made up for planting them on. The latter may be prepared by taking out a trench as for Celery, filling it with a mixture of litter, Grass collected by mowing-machines, long Grass, or anything that will generate some warmth, and cover all with the soil thrown out on either side. Planting or sowing, as the case may be, can be done at the latter end of May.

PEAS you can sow every fortnight from the beginning of April, or earlier if possible, until the end of June. Scarlet Runners should be raised under glass if you require them early, and be transplanted outdoors the end of May. If not, sow outdoors in the second week of May. French Beans may be sown in a warm spot

at the end of April, and during the three following months if a regular supply is required. You would find climbing French Beans very profitable, as they yield pods over a long season, and do away with the necessity for sowing so frequently as when ordinary French Beans are grown.

There are, of course, other vegetables which should be grown, but in a reply of this description exigencies of space will not allow of the subject being further enlarged upon. We have, however, touched upon the most important of them, and hope the advice tendered may prove useful.]

Endive.—This plays an important part in the making of salads through the autumn and winter, but to have it in perfect condition it must be well blanched. If used otherwise it is tough and unpalatable. The moss or green curled Endive can be quickly and effectually blanched either by covering the plants with saucers, slates, tiles, or even strips of boards 11 inches in width if heavy enough to press closely down on them so that light is excluded. If the plants are full-grown or nearly so the blanching will occupy about ten days. The broad-leaved or Batavian Endive is more satisfactory when tied up in the same way as Lettuces. A good few Lettuces should also be tied up weekly, as they will not now form well-blanching hearts unless tied.—G. P. K.

Onions.—All the spring-sown crops, whether in the open or raised in heat should now be lifted, or a second growth which will injure the keeping qualities of the bulbs may begin. All deformed bulbs should be placed by themselves and used first, only those which are likely to keep being stored for the winter. There are many methods of storing Onions, but I know of none equal to that of roping and hanging up in a cool place; the roping can be done under cover on wet days, and every care should be taken not to bruise the bulbs or they, especially the larger ones, will be sure to suffer.—G.

Celery.—The late plantations will now require earthing up. If the bed is dry, a good soaking of clear water should be applied a day or two before the earthing up is done. All side growths and rough leaves should be removed before the plants are tied. After the soil has been piled round the plants the ties can be removed. Frequent applications of soot will be found effectual in keeping off the Celery-fly. Late Celery whose stems have been exposed to the weather and become hard will take seven weeks or eight weeks to blanch. Too much soil should not be placed about the plants at one time, as this is apt to cause a check.—F. W. G.

Potatoes.—Should warm weather again set in Potatoes which are full grown will start growing again unless speedily lifted. This matter should therefore have attention in all cases where the tops have given indication, by dying down, that the crop has arrived at maturity. If there is not time to pick out the seed tubers from the ware now, they can be clamped or placed altogether in the Potato store, to be separated later on when the press of work is not so great.—A. W.

Leeks.—Taking advantage of the fine weather, a final clean down was given to the quarter devoted to Leeks. Previous to hoeing, a tankful of fairly strong liquid-manure was applied. To this had been added some soot-water, this giving the foliage of the Leeks an intense green colour. Afterwards some more soil was drawn up to the stems of the plants, and they will now need no further attention until required for use.—W. McG.

Cabbages have started nicely into growth. In the event of any gaps occurring through attacks of grub or from club-root or other causes, such gaps should be made good without delay. In removing a plant attacked by grub, search for the pest below the ground, following the stem of the plant. Loosen the surface-soil with the Dutch hoe at frequent intervals both at this season and early in the spring.—G.

TREES AND SHRUBS.

MAGNOLIA WATSONI.

This beautiful Magnolia is not at all common in gardens, and good examples are very rare. It was first shown at the Paris Exhibition in 1889. It comes near to *M. parviflora*, but has larger leaves and flowers, the leaves being each sometimes upwards of 6 inches long and from 4 inches to 5 inches wide, while the flowers are each from 5 inches to 6 inches in diameter. The colour is ivory-white on the inner segments, the outer ones flushed with rose, a conspicuous feature being a broad ring of crimson filaments that surround

that retain their leaves throughout winter. Varying a good deal in height, it may be found from a low bush 4 feet high to a large, wide-spreading shrub 12 feet or 15 feet high, and as far through. In the autumn large panicles of flowers appear from the points of the stronger branches, flowers and stalks being cream or white in colour. Black fruits resembling those of the Ivy are produced and plants are readily raised from seed.—D.

The Cornish Heath.—For autumn bloom, the Cornish Heath (*Erica vagans*) may well be associated with the varieties of our other native Heaths. There are several varieties, such as *alba*, *carnea*, *rubra* (a good red), *grandiflora* (with larger flowers), and the newer *St. Keverne* (a lovely form, with beautiful rose or pink flowers). I find that the Cornish

FRUIT.

APPLE CROP, 1916.

UNFORTUNATELY, climatic conditions in the early part of the year did not open favourably in most English orchards, as the blossom was patchy. In some places there was a good and regular show of blossom, but in most cases there were numerous blanks, some kinds flowering freely and others showing no blossom whatever. Certain Apples, such as Lord Suffield and Bramley's Seedling, in Devonshire are good, whilst others, including such favourites as Cox's Orange Pippin, Ribston Pippin, etc., are failures. Con-

Flower of Magnolia Watsoni.

the pistil. When first open the flowers are sweetly scented. It is quite hardy in this country and seems to do best in loamy soil to which has been added a little peat.

Fatsia japonica.—Under the names of *Aralia japonica* and *Aralia Sieboldi* this plant has long been an occupant of our gardens. In many places it is grown as a greenhouse plant rather than a hardy shrub, although it is hardy enough to withstand ordinary winters in many parts of the country. As an outdoor shrub it has much to commend it, for it can be allowed to grow to a great deal larger size out-of-doors than in a greenhouse, and the more generous treatment received by outdoor border culture results in correspondingly fine heads of foliage. Moreover, its large, glossy green, fan-shaped leaves are evergreen, and it forms a distinct feature amongst other shrubs

Heath and its varieties do well in loam, and this is important in view of the popular opinion that all Heaths require peat.—S. ARNOIT.

Veronica parviflora angustifolia.—Most of the shrubby Veronicas are of stiff habit, but this is a very graceful species, with long, narrow leaves, and slender spikes of whitish flowers. It blooms very freely in August and September, and does well in sandy soil. Cuttings taken off with a heel in the autumn root readily. It makes quite a nice little shrub for the rock garden.—N. L.

"The English Flower Garden and Home Grounds."—New Edition, 12th, revised, with descriptions of all the best plants, trees, and shrubs, their culture and arrangement, illustrated on wood. Cloth, medium 8vo, 15s.; post free, 15s. 6d. Of all Booksellers or from the office of GARDENING ILLUSTRATED, 63, Lincoln's Inn Fields, London, W.C.

ditions did not improve as the season advanced, as will be seen from the recent report of the Board of Agriculture, which reads as follows:—

Orchards are not in a healthy condition. Blight is frequently reported, and much damage has been done to the Apples by caterpillars. Apples, Pears, and Plums promise a very small yield.

In a later report the Board states "Apples will be from 40 per cent. to 50 per cent. of a crop in some districts, and only 25 per cent. in others, cooking varieties being much better than dessert." It is gratifying to know that there is an increase in orchards recorded in the returns just published by the Board of Agriculture of 2,490 acres, and that the total under cultivation is 251,320 acres. The import-

ance of good cultivation and spraying is again apparent. The scarcity of labour has undoubtedly resulted in neglected culture, and where caustic washes were applied in the winter, followed by spraying with arsenate of lead during the setting of the fruit, some excellent crops are to be seen.

The new war tax on cyder has created a great deal of feeling in Hereford, Devon, and other cyder-making counties. Dismal reports as to the effect on sales have appeared in the Press of the former county, where it is reported that the trade is being ruined. For this county Mr. G. Laubert asked the following question in the House of Commons, viz., If Mr. McKenna would consider the question of repealing or reducing the tax on cyder in view of the report made to him that sales had fallen 70 per cent. The Chancellor's reply was that no other such representation had been made to him, and, therefore, he could not see his way clear to take steps at present. H. WHITEWAY AND Co., LTD.

The Orchards, Whimple, Devon.

WHITE HEART CHERRY NOT FRUITING.

Why does my White Heart Cherry-tree not bear fruit? For three years, on a sunny, hot north wall, it grew well, and was always a mass of blossom, but the fruit always dropped off. It has for the last three years been growing on a south wall with no better results.—F. S. T.

[The fact of your Cherry-tree being unfruitful may arise from a variety of causes—such, for instance, as a too-dry condition of the soil about the roots, particularly that portion of the border nearest to the foot of the wall. It is astonishing the great amount of moisture the foundation and the portion of the wall buried in the soil above it will absorb, and many a case of fruit-trees failing to set fruit has been traced to this reason alone. Then, again, the roots may have descended into the crude, and, perhaps, in your case a cold and clay sub-soil. This would also account for the blossoms not setting, however freely they may be produced. The fact, too, of the past few seasons having been anything but congenial for the setting of Cherries must not be lost sight of. Then there is the possibility that the tree has become old and worn out, and, therefore, incapable of bearing.]

If, after perusing the foregoing, you give the matter careful consideration, you should be able to arrive at a conclusion as to which of the probable causes named the failure may be attributed. If on examination the border is found in a dry state, the remedy is obvious, and give unstinted supplies of water through the summer and autumn months. If the roots are out of hand, the only remedy is to lift them and lay them out horizontally, or nearly so, as near to the surface as circumstances permit. This, if found necessary, will enable you to afford the roots some fresh compost, consisting of good turfy loam, with a liberal dash of old plaster or lime-rubble mixed with it. This will induce the formation of fibrous roots in abundance if the roots are in a healthy condition, and, barring unfavourable climatic conditions, the fruits should then set freely. To carry out the lifting of the roots successfully you should open out the necessary trench not less than 8 feet distant from the stem, so that the operator will have ample space to work in, and be able to search for and trace the roots without mutilating them more than is absolutely necessary. We do not advise root-pruning in this case, neither would it pay to lift and transplant the tree elsewhere. If root-lifting has to be done, do

this as early in autumn after the fall of the leaf as may be convenient.

In regard to failure arising from adverse weather conditions, there is only one thing to be done in future if you are satisfied such has been the cause, and that is to protect the tree while in bloom. The most effective protection would be covers, long and wide enough to cover the whole of the tree when suspended above it. The covers should reach to the ground, or nearly so, on either side, and be kept clear of the tree by driving stakes into the ground some 18 inches from it, and distant about 3 feet from each other. The covers may be either of canvas or "frigidomo." Nets folded three or four times thick will ward off a good deal of frost.]

GRAPES MILDEWED.

I WOULD be greatly obliged if you could help me with regard to the treatment of a house of Grapes which are terribly mildewed and slightly split. Up to three or four years ago they had done splendidly, then mildew showed itself, and has increased each year. I cut down a large double-flowering Cherry-tree last year, as I was told the roots might have reached the Vine roots, and also might have shaded the Vine a little. The house is full of Grapes.—M. BALLANCE.

[Grapes in such a mildewed condition as those you send us should be cut off at once and burned. Nothing short of a thorough cleansing of both house and Vines will be of the slightest avail. After the Vine has been pruned free both stem and rods of loose bark, and then scrub them with warm water in which a little soap has been dissolved, being careful at the same time not to injure the buds with the scrubbing-brush. Then gather up the prunings, bark, dead leaves, etc., and burn the lot. This done, give the house a thorough scrubbing, using for the purpose a solution made as follows:—In the bottom of a bucket place a good handful of soft soap. Work this into a pasty-looking mixture by gradually pouring in $\frac{1}{2}$ pint of paraffin. When thoroughly amalgamated fill up the bucket with boiling water. Pour one-half of this into another bucket, and fill up both with hot water. Scrub every particle of woodwork and glass with this, and rinse down with clean water. Scrape the walls and lime-wash them, using fresh kiln or lump lime for the purpose. While this is slaking and boiling pour in $\frac{1}{2}$ pint of paraffin. When it has finished slaking add enough water to reduce the whole to the right consistency, and apply while hot. Then dress the Vine with Gishurst's compound, using the latter at the strength mentioned and as directed in the printed instructions to be found on the lid of the box. Keep a good look-out when the Vine makes new growth, and if mildew puts in an appearance dust the affected leaves immediately with flowers of sulphur. If dealt with promptly in this manner the attack can be stayed, but if it is allowed to develop before resorting to remedies it is then difficult to subdue, and oftentimes the crop is rendered useless, as in your case. A cold, close, stagnant atmosphere and cold draughts are generally the cause of mildew appearing in unheated houses, and very careful management is required to ward off an attack.]

NOTES AND REPLIES.

Mouldy Loganberries.—In a recent issue of your paper I noticed a paragraph about dry fruit rot and its prevalence among certain fruits. Among these, the Loganberry was not mentioned; but, as I have found a great many of these go off this year in a way which might answer to your description of the disease, I am anxious to know if it is the same thing with which I have been troubled. I enclose a few specimens, and shall be greatly obliged if

you can suggest anything which might help to prevent it in future years. We have had a rather wet, cold summer, which I was inclined to blame for the trouble, but, possibly, this may have nothing to do with it.—BONACCORD.

[The fungus affecting your Loganberries is not the same as that which causes brown rot of fruits like Plums and Apples, but is the very common mould, *Botrytis cinerea*, which attacks all sorts of fruits and all parts of plants when the conditions are favourable for it, a close, damp, and "muggy" atmosphere being what it likes best. The best way of avoiding it on the Loganberries in future will be to pick all fruit which is imperfectly formed, instead of leaving it to decay, and to give conditions as airy and open as possible.]

Figs in pots.—The Fig is particularly happy under the restriction of pot culture, and no more easily managed fruit can be found for a cool house. It is a common mistake to think that the Fig, coming from a hot climate, does not require much water; a glance at its luxuriant foliage should show it is a water-loving plant. A turfy loam with some mortar-rubble serves as a good potting soil, and rich manure should not be added unless the growth is poor. A hard, moderate growth is what is desired for fruit production, and a cool greenhouse where plenty of air can be given suits it admirably. Small, bushy plants are best for the beginner, but if the house is lofty, standards will be useful as a means of getting near to the glass. For a good all round fruit Brown Turkey still holds the first place. White Marseilles comes next in point of popularity, and is generally the first to ripen; though called white it is really pale green. The two Ischias, Black and White, should be included in every collection; "small but good" will be the verdict of those who try them. In my opinion there exist nothing more delicious among Figs, and as they are both prolific croppers they will supply all needs save those of the exhibition table, that altar on which so many good things are sacrificed. For two late varieties, Bourjasotte Grise, most delicious in flavour and medium in size, a regular and constant bearer, and Negro Largo, a fine large fruit which is almost black and of very rich flavour, will finish the season.—E. A. BUNYARD in *Garden*.

Cropping young Vines.—If Vines were not allowed to carry a single bunch during the first two years of their life a much greater weight of fruit could be taken from them in after years. The bearing powers of many Vines are undoubtedly wonderfully lowered by overcropping in the earlier stages of their existence. There is a natural desire on the part of amateurs to get a crop of fruit as soon as possible after planting, but it would be better if the first thought were given to securing strength and permanent fertility in the Vines. It would be interesting to note the difference of girth of stem in two sets of Vines, one of which had been cropped in the ordinary way from the first year after planting, the other not having been allowed to fruit during the first two seasons. It requires, however, more self-denial to wait until the third year from planting than most Vine growers are possessed of. Growers for profit are naturally anxious for a quick return on the outlay incurred in building and planting, the modern system being to crop heavily and feed liberally from the time the Vines come into bearing. Very few would care to wait a couple of years before taking a bunch of fruit from their Vines however great the advantages might be in the long run. Cropping very lightly for the first two years is, however, very different from tax-

ing the capacity of the Vine to its full extent. When Vines are cropped rather beyond their powers during the first two or three years they do not seem to be able to do themselves justice in after years.

ROOM AND WINDOW.

THE FENNEL-FLOWER (NIGELLA).

The Nigellas are all hardy border annuals. Some few have been in cultivation now for a number of years, and may, in fact, be classed amongst the oldest of our hardy border flowers. That they have so long found a place in our gardens need occasion no surprise when their singular-looking flowers and the cut foliage are taken into consideration, while the old-fashioned names of "Devil in a Bush" and "Love in a Mist," under which they had hitherto been known and grown, are likely to cling to them for years to come. Although some handsome varieties are to be found among the older introductions, none can approach

more effective can be imagined than this, seen in scattered groups on a mixed border or growing in a mass in a special corner of the garden. It requires a minimum of trouble, and after the first sowing it will continue to propagate itself by self-sown seeds. I have in mind a garden in which it has come up year after year for upwards of twenty years. For table decoration it is delightful, more especially in artificial light. I should advise all who have not grown it to give it a trial next year, and I am sure they will be more than pleased with the result.

NOTES AND REPLIES.

Cutting flowers.—It is a great mistake to allow flowers to fully expand before cutting them. For more than one reason it is better to cut the blooms when about two-thirds expanded. In the first place they last much longer. When they open fully in water they come larger, and in the case of continuous flowering things,

The Fennel Flower (*Nigella hispanica*).

the new one, named Miss Jekyll, either for its habit of growth or for the beauty of its flowers. No other variety has such lovely blue flowers as this, and, having the further advantage of being borne on long stalks, the blossoms are well poised amongst the elegant slender foliage, and are seen to great advantage. It is also an exceedingly free-flowering variety, lasting for a long time in good condition, and when grown in groups, as it should be, forms a singularly beautiful object in the mixed flower border.

Seed may be sown in the autumn if an early display of bloom is required. On the other hand, if it is preferred that the plants should flower in the late summer or early autumn the first or second week in April is quite early enough to sow the seed.

Mr. L. C. Ashton, Perry Bar, Birmingham, whom we have to thank for the photograph from which our illustration has been prepared, writes as follows:—

This beautiful hardy annual should find a place in every garden. Nothing

the blooming season is lengthened. Take Daffodils, for instance; the difference between blooms that remain until fully open on the plant and such as are cut when about half expanded is very noticeable. Placed in a cool room, the blooms will come quite one-sixth larger, and the same thing is observable to a more or less greater extent with all flowers that can be used in a cut state. When sending flowers away I make a point of cutting them at least twenty-four hours before I despatch them. They become so highly charged with moisture that they bear the journey much better. Gladioli are wonderfully improved by early cutting. In very hot weather the lower flowers go off before those above them can open, so that one cannot get a spike with more than two or three blooms on it. By cutting as soon as the first two blooms are opened, and keeping them in a cool place, one gets some well-furnished spikes. Paeonies, Irises, and some other things cut when just showing colour will last very much longer than if allowed to open on the plants.—T.

ROYAL HORTICULTURAL SOCIETY'S VEGETABLE SHOW.

SEPTEMBER 26TH, 1916.

This was held in conjunction with the Society's fortnightly meeting on September 26th, and, from many points of view, was a considerable success. High class produce was general, and competition in the more important classes fairly keen. A champion cup offered by the Society to the winner of the greatest number of first prize points throughout the whole exhibition—the winner in Class 1 being excluded—was won by Mr. James Gibson, gardener to His Grace the Duke of Portland. A gold medal was awarded to Messrs. Webb and Sons, Stourbridge, for a highly representative collection of vegetables, everything being first-class and admirably set up. An exhibit of Premier Onion, some six or seven dozen bulbs in all, giants in their way and each a replica of the other, gained a silver Knightian medal for Messrs. Dickson and Robinson, Manchester, a like award going to Messrs. Sutton and Sons, Reading, for an exhibit of Scarlet Runner Beans showing the development of this much-esteemed vegetable. Starting with the common Scarlet with thick, curved pods of 6 inches in length and proceeding by way of Champion, Ne Plus Ultra, Sutton's Scarlet, one of the most prolific with pods each 10 inches in length, its present ultimatum is seen in Prizewinner and Best of All, which are between 17 inches and 18 inches in length, perfectly straight, proportionately broad, young and succulent withal. Pods of all were shown on a board, and in the foreground, dishes of these with climbing French Beans and coloured-podded sorts.

In the competitive section the largest class was for twelve kinds, distinct, to be selected from a scheduled list, the "Sutton" challenge cup being included in the first prize. This was secured by Captain H. Spender-Clay, M.P., Ford Manor, Lingfield (gardener, Mr. D. Gibson), who showed admirable produce; second, His Grace the Duke of Portland, Welbeck (gardener, Mr. James Gibson), with an exhibit for all practical purposes just as good. Indeed, speculation was rife as to the points separating these two exhibits, some considering the latter the better of the two. Both were, however, excellent, reflecting the highest credit on the growers. A chief object of Class 2 for nine distinct kinds was the exhibiting of those vegetables which are most useful and acceptable for table, the judges being empowered to disqualify any exhibit opposed to this principle. Hence for once we were confronted with examples of moderate size as opposed to those of exhibition order pure and simple. Seven collections were staged, the leading award going to Mr. H. Myers, Swanmore Park, Bishops Waltham (gardener, Mr. G. Ellwood), for a really useful lot. We regarded his dishes of Best of All Tomato and Dwarf Gem Brussels Sprouts ideal for table use.

In the class for six kinds Mr. T. Jones, Ruabon, showed some of the finest Red Intermediate Carrots we have seen. His other dishes were also fine. The Potato classes, whether here or elsewhere, are generally well contested, six collections of twelve distinct varieties being staged, the Rev. T. McMurdie, Woburn Park, Weybridge (gardener, Mr. A. Basile), receiving the premier prize for produce bordering on perfection. Practically without spot or blemish, and of a high standard of excellence throughout, the exhibit found many admirers. Only four staged in the class for six varieties of Onions, Mrs. Jenner, Wenvoe Castle, near Cardiff (gar-

dener, Mr. H. Wheeler), being first. In the single dish class for Runner Beans sixteen competed, the prize being awarded to Miss E. L. Bradshaw, Steeple Ashton, Oxford (gardener, Mr. R. Wadham), for a particularly handsome exhibit. The variety was Prizetaker. For a dish of Brussels Sprouts nine dishes were set up, Mr. T. Jones, Ruabon, being an easy first with a perfect dish of Dwarf Gem, the tight little "buttons" ideal for table use. We grew this variety in preference to all others, and know something of its nut-like flavour, and were pleased to note that it was favoured by the judges in a keen competition. It is not likely to satisfy the market man, but for those desiring the highest table quality and a Sprout which may be partaken of whole, we know of nothing to equal it.

ROYAL HORTICULTURAL SOCIETY'S FRUIT SHOW.

OCTOBER 3RD AND 4TH.

No greater tribute to the enterprise and enthusiasm of British horticulture could possibly have been paid than the excellent exhibition of fruit brought together on the above-named dates. Ranking high with the best that have preceded it—albeit the exhibits of several eminent fruit-growing firms were, on this occasion, conspicuous by their absence—it was superior to them all in the Grape classes, which never before have been so keenly or so numerous contested. In these alone, apart from those reserved for collections of dessert fruit elsewhere, over 200 bunches of, for the most part, excellent produce were staged, their quality proving that the leading horticulturists are as keen and alert as ever. This, in these strenuous times, remembering the increased difficulties of labour and transit, is saying much, the wide area from which they came demonstrating not a little enthusiasm. Grapes of such excellence as would a year ago have been well in the running for prizes were upon this occasion passed over. Apples, too, if not quite equal to the prime quality to which we have become accustomed, were, nevertheless, very fine, a remark which has an all-round application—the big and county classes and single dishes alike. In only one direction did a jarring note occur. This was a collection of fruit set on gawky stands. Out of scale with the rest of the exhibits, the painted legs of these were too painfully evident, and we saw the thicket of these rather than the fruit at their summit. Good fruit needs no such exalting, it is seen to greater advantage at, or immediately below, the line of vision. Following are brief particulars of the show, which, owing to lack of space, we are unable to give in detail.

OPEN TO GARDENERS AND AMATEURS.

Three exhibitors staged collections of nine dishes of ripe dessert fruit, Lord Somers, Eastnor Castle, Ledbury (gardener, Mr. G. Mullins), occupying the leading place with particularly good fruit. Muscat of Alexandria and Black Hamburg Grapes, Peaches Sea Eagle and Barrington, and Doyenne du Comice Pears were very fine. The Duke of Newcastle (gardener, Mr. S. Barker), who was second, had admirable dishes of Crimson Galande and Princess of Wales Peaches, and Pears Triomphe de Vienne and Marguerite Marillat. In that for six dishes of ripe dessert fruit five collections were staged, the whole making a considerable display. Here Lord Hillingdon, Wildernes, Sevenoaks (gardener, Mr. J. Shelton), gained the premier award, Madres-

field Court and Muscat of Alexandria Grapes, Charles Ross Apple, and Lord Palmerston Peaches being in every way excellent.

The Grape classes throughout, as already hinted, were of high excellence, worthily reflecting the skill of the British gardener. In the leading class for six distinct varieties (two bunches of each) six collections were staged. Arranged in crescent-shaped outline, the whole made a telling display; a great attraction to gardeners and visitors alike. The chief prize winner was the Duke of Newcastle, Clumber, Work-sop, who staged Black Hamburg, Buckland Sweet-water, Chasselas Napoleon, Madresfield Court, Muscat of Alexandria, and Gros Colman as his six. These merited the highest praise, good finish and uniform size being notable features. Mr. W. Mackay, Ascog, Bute, N.B. (gardener, Mr. D. Halliday), was in the second place with Grapes of excellent quality, while the bunches of Appley Towers staged by Mr. G. Miller, Radlett, who took third prize, approximated to perfection. The Black Hamburg class for two bunches brought eight contestants, Lord Hillingdon sending perfectly-finished, well-berried examples of this popular sort, and gaining first prize. Lord Saville, K.C.V.O., Rufford Abbey (gardener, Mr. J. Doe), was second with excellent Grapes. Lord Hillingdon also sent the best bunches of Mrs. Prince and Madresfield Court, superb quality and perfect finish characterising the whole, Mrs. W. Raphael, Englefield Green, having the finer bunches of Black Alicante. Seven staged in each of the two latter classes. For Muscat of Alexandria the Duke of Newcastle, Clumber, Work-sop, led, Lord Somers, Eastnor Castle, Ledbury, following. The finest bunches of this highly-esteemed variety, whether for size of bunch or berry, gained no prize, doubtless due to the lack of table fitness of the moment. They were probably thrice the weight of the first prize lot, and even in their unripe state reflected the highest cultural skill. They came from Mr. C. W. Mann, Bexley, Kent (gardener, Mr. J. Simon). Lord Somers sent the best collection of hardy fruits—thirty dishes, distinct, grown entirely in the open, to include not more than twelve of Apples or eight of Pears. These were of excellent quality, and, with Peaches, Nectarines, Cherries, Figs, and Plums, made up a sumptuous and representative whole.

NURSERYMEN'S CLASSES.

In the premier class—space allowed, 30 feet run of 6 feet tabling—two exhibitors staged, the gold medal as first prize being awarded to Messrs. H. Cannell and Sons (manager, Mr. J. Lawson) for a high-class collection embracing nearly 250 dishes of Apples, Pears, and Plums. A few weeks earlier, with all fruit at a standstill, owing to the prevailing dryness, this exhibitor doubted whether there would be any fruit to show, hence such excellence as obtained was all the more surprising. Notable dishes of Apples were Egremont Russet, Winter Ribston, Charles Ross, James Grieve, Bramley's Seedling, and Warner's King. Plums Monarch, Belle de Septembre, Coe's Golden Drop, Archduke, and Wyedale were remarked. In the following class—space, 20 feet by 6 feet—Messrs. J. Cheal and Sons led against four competitors, staging clean, well-developed fruits throughout. Prince Albert attracted by colour at once, Egremont Russet (a fine dish) because of its excellent table quality. Gascoyne's Scarlet, Rev. W. Wilks, and Blenheim Orange were other dishes of importance. Messrs. Laxton Brothers were second, and, while staging good Apples and Pears, and Plums

Monarch and Claude de Ravay, also contributed dishes of promising cross-bred Plums as yet unnamed. Messrs. Thomas Rivers and Sons alone exhibited orchard-house grown fruit and fruit-trees in pots. The fruits of Cox's Orange Apple were particularly attractive by reason of colour, while trees of Plums President and River's Late Orange demonstrated the prolific cropping qualities of these valuable sorts. Trees of Peaches, Salway, Sea Eagle, and Thomas Rivers, carried heavy crops. Gathered fruits were excellent.

MARKET GROWERS ONLY.

Messrs. Gaskain and Whiting showed the best twenty baskets of cooking and dessert Apples, Lieutenant-Colonel H. Lumley Webb being second. The first-named lot was very fine. For twelve baskets, six cooking and six dessert, the Horticultural College, Swanley, deservedly secured the premier award, Warner's King, Peasgood's Nonsuch, Bismarck, Golden Noble, Lane's Prince Albert, Cox's Orange Pippin, and James Grieve representative of the finer sorts. Well-finished fruits and good staging characterised this exhibit. Only one exhibitor, Lieutenant-Colonel Lumley Webb, staged six baskets of Pears. They were excellent, the first prize being awarded. The whole of the fruit shown in this section, it is interesting to note, was Kent grown.

THE WEEK'S WORK.

OPEN-AIR GARDENING.

IN BLOOM OCTOBER 4TH.—*Michaelmas Daisies* (in great variety), *Helianthus* (in variety), *Helconium*, *Enocheras*, *Pentstemons* (in variety), *Rudbeckias*, *Scabiosa* (in variety), *Herbaceous Phloxes*, *Annual Delphiniums*, *Salvias* (in variety), *Lobelia cardinalis*, *Bergamot*, *Linums*, *Phygelius capensis*, *Montbretias*, *Gladiolus*, *Lilium speciosum* (in variety), *Tritomas*, *Amaryllis Belladonna*, *Statice* (in variety), *Dahlias*, *Antirrhinums* (in variety), *East Lothian Stocks*, *Myosotis*, *Campanulas*, *Echinops*, *Achilleas*, *Lavatera Olbia*, *Agapanthus umbellatus*, *Hardy Cyclamens*, *Colchicum autumnale*, *Crocus speciosus*, *Bunch Primroses* (*Polyanthus*), *Mesembryanthemums*, *Anthemis Kelwayi*, *Sedum Sieboldi*, *S. spectabile*, *Cosmos*, *Convolvulus mauritanicus*, *C. Cœneum*, *Androsaces* (in variety), *Linarias*, *Potentillas*, *Gypsophilas*, *Hutchinsia alpina*, *Ethionemas*, *Plumbago Larpetæ*, *Erigerons*, *Francoas*, *Sweet Sultan*, *Early-flowering Chrysanthemums*, *Ericas* (in variety), *Menziesias*, *Hypericums*, *Genista tinctoria*, *Spartium junceum*, *Buddleia variabilis magnifica*, *Abelia rupestris*, *Clerodendron trichotomum*, *Veronicas* (in variety), *Myrtle*, *Hardy Fuchsias* (in variety), *Hydrangea paniculata grandiflora*, *Laurustinus*, *Viburnum coriaceum*, *Ceanothus* (in variety), *Tricuspidaria lanceolata*, *Solanum jasminoides*, *Polygonum baldschuanicum*, *Magnolia grandiflora*, *Clematis* (in variety), *Wistaria*, *Roses* (in variety), *Pampas Grasses*, *Artemisia lactiflora*, *Solidagos*, *Primula capitata*, *Water Lilies*.

WORK OF THE WEEK.—The herbaceous borders were again looked over during the week, clearing away all dead flower-stems and annual plants which have finished flowering, and removing stakes which are no longer needed. The position of all deciduous bulbous plants is marked with labels, so that when the border receives its annual dressing the dormant bulbs and corms may not be disturbed. Early-planted Gladioli, having ripened their foliage, have been carefully lifted and laid with the stems attached in a cool-house to dry. Before storing them for the winter, all offsets are rubbed off and the corms graded into different sizes. Both the tuberous and fibrous rooted Begonias are still flowering freely. Cannas have been examined, and the best varieties marked for propagation in the spring. Directly the leaves have been blackened by frost the foliage will be trimmed off to within 5 inches or 6 inches of the ground and the roots lifted and stored for the winter.

It is not always necessary to dry them, but if very wet it is advisable to allow some of the superfluous moisture to escape before storing them. Autumn-flowering Chrysanthemums are blooming freely, and notes have been made of the most useful varieties as a guide to propagation. All cuttings in cold-frames are examined from time to time for the purpose of removing decayed leaves and weeds that have come up in the soil. Very little water is required, and when it is necessary it is given on fine mornings. Calceolaria and Pentstemon cuttings are now well rooted, and an abundance of air is admitted on all favourable occasions. Plenty of good cuttings of Tufted Pansies (Violas) are now available, and another batch of Gazania cuttings has also been put in, choosing the smaller shoots which have no flower-buds. These are inserted at about 2 inches apart on a bed of sandy soil and kept close and shaded until rooted. Specimen plants in tubs are beginning to look shabby, and have been removed to a place where they can be protected when necessary. Hydrangeas and similar subjects will be left out-of-doors for some time, and will come to no harm if a little tiffany is thrown over them when frost is expected. If a glass-house is not available, these may be wintered quite well in a barn, stable, or similar structure.

F. W. GALLOP.

Lilford Hall Gardens, Oundle, Northants.

SOUTHERN COUNTIES.

Cucumbers.—The plants intended for fruiting during the next few months should now be making vigorous growth and fast covering the trellis with bine. Until the trellis is covered, the plants should not be allowed to bear. Cut off all fruits as they appear for the present, and take the points out of young shoots to make them break and produce secondary shoots. In this way the trellis can speedily be covered with healthy growth, which, when allowed, will then produce fruit in succession over a long period. Ventilate freely on every favourable occasion, and syringe the foliage twice daily with tepid water. In the interval maintain a moist atmosphere by frequently damping down. Top-dress on the little-and-often principle, and do not, so long as growth is satisfactory, resort to the use of stimulants. Plants still in bearing should be induced to continue so for some time longer by supplying the roots with rich top-dressings and stimulants when watering. Liquid-manure sprinkled on the paths when banking up at night will also be beneficial. Keep red-spider in check by a free use of the syringe in bright weather, and remove a few at a time of the oldest of the leaves if there is plenty of younger ones to take their place. Regulate the supply by allowing no more fruits to develop in various stages than will be required for consumption.

Hardy fruit garden.—Preparation for lifting the roots of fruit-trees to check exuberant growth or where trees have got out of health as a result of the roots having descended into a cold, sour subsoil can now with safety be made and the operation undertaken afterwards. In some instances new compost or a modicum of it is required when the roots are laid out afresh, and in the case of stone fruits lime rubbish is also needed if the soil in its present state is either devoid of it or it is present in insufficient quantities. Drainage material may also be needed, particularly where the subsoil is very moist or likely to become flooded in wet weather—i.e., if concreting, the best of all remedies in such cases, cannot for various reasons be afforded just now. It is not always necessary to lift the whole of the roots of a tree in order to administer the needful check. This can often be done by opening a trench some 6 feet away from the stem and lifting or baring the roots to some 3 feet or 4 feet away from the bole, laying them out afterwards after trimming off broken ends and shortening back the strongest in a nearly horizontal position, adding lime rubbish to the soil in the case of stone fruit, even if nothing further is required. Unfruitful Apricot, Peach, and Nectarine trees may be restored to a healthy and fertile condition by the adoption of these principles. With regard to the first-named fruit, a total lifting of the roots, if the trees bear but sparsely, gum, and

make rank growth is absolutely necessary to counteract the tendency which Apricots have to get into such a condition when improperly planted. For Apricots a very liberal quantity of lime rubbish should be added to the soil, and ample drainage provided beneath the roots, as considerable supplies of water are necessary when the trees are in full growth and carrying a good crop of fruit.

Root pruning.—Where this has become necessary the results are of a more satisfactory character if undertaken now than during the resting period, as the fact of the foliage still being green is the means of the trees overcoming the shock caused by the severance of the large roots more quickly and induces them to push out new fibres soon after the conclusion of the operation. When the trees are at rest they do not recover nearly so rapidly. One-half of the roots only should be operated on in each case in one season, leaving the other half to be dealt with either in the following year or the year after. When it is found that the soil has become exhausted, it is a good plan to mix some good fibrous loam with the staple when refilling the trench, as this and a little burnt soil, if at hand, encourage the emission of fibrous roots. When root-pruning is about to be undertaken, the necessary trench should never be opened nearer the stem of the tree than 3 feet. The operator should be guided in this matter by the age and the spread of its branches in every instance, and not by any set rule.

A. W.

MIDLAND COUNTIES.

Apples.—With the exception of a few very late varieties, the majority of these have been gathered. Apples generally are below the average in size this year, and they are far from plentiful. Therefore, it is necessary to take extra care in gathering and storing, as any carelessness either in selecting the fruit or in handling it will have unsatisfactory results. The greatest care should be taken in the handling of the fruits in order that they may not be bruised, and every fruit that is not perfect should be set aside for present consumption. Much of the shrivelling noticed in late Apples in the spring is the result of their being stored in too dry an atmosphere. A cool dark room, with atmospheric conditions similar to those generally found in a good cellar, is an ideal place for preserving fruits. Indeed, there are few fruit rooms that are better than a good cellar for the purpose. No straw, hay, or other material should be used in the fruit room, as it is apt to become musty and taint the fruit.

Figs.—The cold and damp weather early in the summer retarded the growth of Fig-trees, the result being that very few good fruits have been gathered in this locality. The trees have since made a considerable amount of growth, which needs all the sun and air possible to mature it. All weak and unnecessary shoots have been cut out in order that those retained for fruiting next year may be well exposed to full air and sunshine.

Perpetual-flowering Carnations.—The temperature of the house in which these are growing is maintained at 55 degs. at night, with an advance of 5 degs. during the day. Ventilation is afforded regularly, leaving the ventilators open a little during the night, and in cold weather on the opposite side to that from which the wind is blowing. An abundance of fresh air is admitted during favourable weather, when the paths are damped twice daily. Occasional applications of clear soot-water are afforded, as these impart a deep, healthy colour to the foliage. A slight top-dressing of an approved Carnation manure is given fortnightly throughout the flowering season, taking care to avoid an overdose. Malmaisons layered last August and potted into 3-inch pots are now ready for repotting into 5-inch and 6-inch pots, according to the progress made since the last potting. The pots must be clean and dry, and have ample material for drainage. The potting compost used is of a slightly rougher nature than that for the previous potting, adding mortar rubble and broken charcoal. The plants are placed as near the glass as possible, allowing ample ventilation in favourable weather. Through-

out the winter the plants require to be kept slightly on the dry side at the roots, but never allow them to suffer from excessive dryness. This type of Carnation is very subject to a fungoid disease known as rust, but if the house is kept dry and well ventilated during the dullest part of the year disease is not so troublesome.

Turnips have done exceedingly well, the season having been an ideal one for this crop. Late sowings should now be thinned to 6 inches apart, stirring the ground between the rows directly the thinning is done. Soot is one of the finest stimulants for this crop, and an application once every ten days is not too frequent. On very poor ground a frequent slight application of an artificial manure will be very beneficial. Roots which have grown to full size should be lifted and stored before they become too large for use. Store them in ashes or sand, but avoid placing them in too great bulk.

Celeriac has made excellent growth during the last six weeks. The crop must shortly be lifted, the foliage trimmed off, and the roots stored in sand in a place secure from frost.

Winter Greens.—A few late plants may still be planted on vacant ground, and provided the winter is not too severe will prove useful later. The earliest-planted Kales have made good growth. Stir the land occasionally and draw a little soil up to any plants that need it. Remove decaying foliage so that air and light may reach the plants. Late Leeks that were planted on well-prepared ground have done exceptionally well, and little attention beyond an occasional hoeing has been necessary. Up to the time of writing we have only registered 2 degs. of frost, which has done no damage. Frosts may now occur any night or morning, therefore every preparation should be made to guard against injury therefrom.

French and Runner Beans have yielded splendid returns, and most of the plants are still in full bearing. French Beans, which were sown in a warm border for fruiting late, are just coming into bearing. These are protected by placing a temporary frame-work over them with spare lights thereon. These will be further covered with mats at night when severe frosts are likely to occur; and good crops are expected until the end of October.

F. W. G.

SCOTLAND.

Cuttings.—The work in connection with cuttings was brought to a close in the course of the week. This included the putting into cold-frames upon previously prepared beds the more hardy things which are used from year to year. Departing from the usual practice, nearly a thousand cuttings of Antirrhinum were made. The strain is an excellent one, the plants being of a good intermediate habit, very free-flowering, and true to description. It is thought that by using these cuttings a considerable amount of work will be avoided in spring, in the way of sowing, pricking-off, etc. At the same time, cuttings of Tufted Pansies were put in. These included, among others, a good quantity of the favourite Maggie Mott, of the neat little Violetta Waverley, and of a good form of the old Viola cornuta named Thuringia, which is very effective when massed and flowers freely over a long period. Cuttings of Pentstemons were likewise attended to. We have for the present discarded the "florist" varieties of these showy flowers; but the useful Gem family is largely used, chiefly Newbury Gem, Southcote Gem, and an unnamed variety almost equally good, which originated in a neighbouring garden a few years ago. With the insertion of a small number of Calceolarias—these being put in merely to keep up the stock—the cutting season may be said to have come to an end.

Dahlias.—These showy autumn flowers have made excellent growth, and during the week decayed blooms and superfluous shoots were removed. With the advancing season the flowers do not endure so well as they did, and if decaying blooms are not promptly removed they are apt to contaminate others which are on the point of expanding. As has been indicated in previous notes, a large quantity of the old Glare of the Garden is used, and dur-

ing the present rather peculiar season it has well maintained its popularity. On the other hand, I have to some extent revised my opinion as to the value of the Giant-flowered or Pæony-flowered section. These are, beyond question, very massive and showy, but if the quarter in which they are grown is a trifle rich, the growth is vigorous, not to say gross, and the blooms verge upon the monstrous. It appears, therefore, that this section is more fitted for use in shrubberies or in similar positions. The Cactus, Collarette, and single Dahlias are better adapted for general decoration.

Pits in which Melons and Cucumbers were grown during summer and early autumn have now been cleared of the hotbeds. The maure is wheeled straight to any vacant break, and afterwards the pits, which are about 8 feet deep, will be thoroughly lime-washed. These pits are very useful for storing cuttings of tender subjects over winter, and, being heated by hot-water pipes, frost can be easily kept at bay. Such things as Arum Lilies, too, succeed perfectly well in these pits until they are required for the greenhouse.

Potting.—A day was devoted to potting in the course of the week. *Primula obconica*, *P. sinensis*, and *P. malacoides* were given a move on. It is again intended to grow a batch of *P. malacoides* in 10-inch pans—this being, as I think, the most effective way of growing this useful variety. Careful watering is now essential in the case of the family generally, few plants resenting an excess of moisture so quickly as the *Primulas*. Some promising *Cinerarias* were also put into larger pots—chiefly those 7 inches and 8 inches in diameter. A batch of *Schizanthus Wisetonensis* was moved into its flowering pots. These plants had been pinched some time ago and have broken freely. Meantime, a light stake was placed in the centre of each pot to which the growths have been loosely tied. Leaf-cuttings, now well rooted, of *Saintpaulia ionantha* were potted off, and some plants of *Begonia Gloire de Lorraine* were given a shift.

Plant-houses.—Now comes the time when, in order to make room for winter-flowering stuff, no hesitation should be felt in discarding plants of no intrinsic value. Most of us, I daresay, grudge to part with plants which have taken time and care to grow, but, after all, when they have served their purpose it is as well to let them go. For example, such things as *Coleuses* should be got rid of with the exception of sufficient stock plants. The same course may very well be followed in the case of *Fuchsias*, of *Zonal Pelargoniums*, of *Diplacis*, *Celsias*, *Petunias*, and so forth. There is (in my own case, at all events) a tendency to retain too many plants. Over-crowding leads at times to insect pests, and, therefore, it is better to harden the heart and discard freely. In the greenhouse the display still remains tolerable, and with regular picking and careful watering no further rearrangement will be necessary until the *Chrysanthemums* are housed. Seedling *Begonias* of the present year's growth have lately been useful. The proportion of good doubles and semi-doubles is larger than usual. As regards the stove, late-flowering plants of *Pancreatium* fragrans are showing the flower-stem. These useful and sweetly-scented subjects are always appreciated, more especially after the outside display begins to wane. *Gesneras* are at present useful, and *Pentas rosea* is beginning to show up well. The earlier *Cypripediums* will very shortly be in bloom, and *Eucharis amazonica* and *Cælogyne cristata* are coming on apace. *Ixoras* are always attractive and useful. These, however, require more heat than the ordinary run of stove flowering plants; and the heat must not be intermittent. Among roof plants, *Thunbergia laurifolia* is a fine thing, and blooms almost continually during the winter. This plant and *Passiflora quadrangularis*, in my opinion, are more valuable than *Clerodendrons* or even than *Allamandas* as stove roof plants. The cool-house provides as yet sufficient heat for such things as *Libonia floribunda* and a spare batch of *Gesnera cinnabarina*, both of which will be very useful at a later date. Damp is easily dealt with as yet by means of moderate firing and by strict attention to ventilation on all suitable days. W. McGRUFFOG.

Balmæ Gardens, Kirkcudbright.

CORRESPONDENCE.

PLANTS AND FLOWERS.

Wintering plants in a cold house (M. W.).—*Chrysanthemums* and *Calceolarias* might be safely wintered in an unheated greenhouse—but not so *Pelargoniums*, as frost and damp will certainly destroy them. It would be much the best plan to heat the house with a small hot-water apparatus, if *Pelargoniums* and other tender greenhouse plants are required to be kept safely in it through the winter season.

Salvia splendens (F. S. T.).—If you have any old plants your best way will be to keep them in the greenhouse during the winter. These plants will, in the spring, push out a quantity of new shoots, which will make first-rate cuttings, which, if put into pots and stood in a propagating case, will very soon root. These should be potted off when rooted and grown on in the same way as *Chrysanthemums*.

TREES AND SHRUBS.

Swellings on Pine-tree stems (W. A. East).—The swellings on the stems and shoots of your *Picea nobilis* are caused by a fungus (*Peridermium elatinum*). This fungus has also another form in which it appears on the leaves of the attacked parts of the tree, as small, more or less cup-like projections filled with spores. Spraying with a fungicide just at the time when the spores were ripe might have some effect in checking the spread of the disease, but it would have no effect on the swollen shoots where the fungus is safely doing its work beneath the bark. Practically the only thing to save the tree is to cut off and burn the infested shoots and branches.

FRUIT.

Spotted Apples (F. Otway Johnson).—The spotting on the fruit is caused by a fungus brought about, no doubt, by the roots getting into a cold subsoil, which cannot supply proper food. You should open a trench round the tree, 4 feet or 5 feet from the stem, and sever all downward roots, refilling the trench with some good turfy loam, bone-meal, and wood-ashes, mulching the surface afterwards with rotten manure. You should also in the winter, when all the leaves have fallen, syringe the tree with the caustic solution which we have so often advised in these columns, as this would destroy the spores of the fungus, which seldom attacks healthy trees.

SHORT REPLIES.

H. W. Coutley.—We have never heard of the Privet leaves being injurious to poultry.—**W. E. E.**—The best manure for such a soil as yours is cow-dung, this keeping the soil cool. You should dig in one of the several soil fumigants now on the market.—**Mrs. Herbert Paul.**—There are no better *Roses* for your purpose than the one you mention and *Zephrin Drouhin*, but if you wish them to succeed in such a position as you refer to your best plan will be to have the tiles lifted and a border, consisting of good loam, some rotten manure, and a few bones, made for the *Roses*. Evidently the soil is exhausted and the border dry at the bottom, hence the attack of mildew.—**Canterbury.**—1, During the winter *Cinerarias* must be kept in a house the temperature of which does not exceed 40 degs. to 45 degs. They may be kept in a heated frame, if the heat can be turned on when the weather is severe to keep the temperature at the figures given above.—**Margaret Wilson.**—Your best way will be to wait until the leaves fall, then have all the old wood cut out, laying in the young shoots that will bear the fruit next year at a distance of about 4 inches apart, spurting back to two buds those not required for filling in. 2, The shoot you refer to is probably a sucker, and should at once be dug up as it is only weakening the tree.—**Wood.**—We doubt very much whether with such a tall building so near you would get the *Roses* and *Clematis* to do any good. If you do decide to try them, then you have a wide selection in the many varieties of *Rambler Roses* and *Clematis* now to be had. We see no reason why you should go to the expense of tubs; old barrels sunk in the ground will answer quite as well and can

be had cheaply. For the green-fly, get some *Quassia* extract and soft soap, which can be had from any horticultural sundriesman.

NAMES OF PLANTS AND FRUITS.

Names of plants.—*E. B.*—*Polygonum baldschuanicum*.—*F. Keane.*—*Erigeron multiradiatus*.—*Miss Wauchop.*—One of the many forms of *Aster cordifolius*.—*M. T. Gray.*—The plant you refer to as "The Silver Sage" is *Petrovskia atriplicifolia*.—*J. B.*—*Leycesteria formosa*.

Names of fruits.—*Anon.*—Pears: 1, Fondante d'Automne; 2, Dr. Jules Guyot. — *C. H. G. P.*—Small fruits of Cox's Orange Pippin.—*Amelia.*—Plum Transparent Gage.—*A. G.*—1, Cellini; 2, Medium-sized fruit of Kentish Filbasket.—*J. J.*—Apples: 1, Hawthornden; 2, Lemou Pippin; 3, Alfriston; 4, Worcester Pearmain.—*C. L.*—Apples: 1, Duchess of Oldenburgh; 2, Yellow Ingestre. Pears: 3, Louise Bonne of Jersey; 4, Beurré Superfin.—*E. N.*—Apples: 1, Stone's (syn. Loddington Seedling); 2, Cox's Orange; 3, Mère de Menage; 4, Cellini.—*A. Grant.*—Apples: 1, King of the Pippins; 2, Warner's King; 3, Lord Suffield; 4, Laue's Prince Albert.—*A. R. H.*—Plum Coe's Golden Drop.—*W. C. L.*—Apples: 1, Emperor Alexander; 2, The Queen; 3, Cox's Pomona; 4, Golden Spire.—*A. E. J.*—Apples: 1, Stirling Castle; 2, Cellini; 3, King of the Pippins; 4, Ribston.—*W. P.*—Apples: 1, Hawthornden; 2, Warner's King; 3, Alfriston; 4, A very poor Cellini.—*T. H.*—Pears: 1, William's Bon Chrétien; 2, Durondeau; 3, Beurré Bosc. Apple: 4, King of the Pippins.

CATALOGUES RECEIVED.

JOHN WATERER, SONS, AND CRISP, LTD., Twyford and Bagshot.—Home-grown Bulbs and Fruit-trees.

R. WALLACE AND Co., Colchester.—List of New Chinese Plants, Lilies, Tulips, etc., etc.

M. M. LEMOINE AND SON, Rue du Montet, 136-142, Nancy, France.—General Catalogue of Plants.

Summer-fruiting and autumn-fruiting Raspberries.—Trials of both summer-fruiting and autumn-fruiting Raspberries will be held at Wisley. Three plants of each variety should reach the Director, R.H.S. Gardens, Wisley, Ripley, Surrey (station, Horsley. L. & S.W. Ry.), by November 13th, 1916, accompanied by the necessary forms of entry (one for each variety), which may be had on application to the Director.

NOTES OF THE WEEK.

Ducks in pleasure-grounds.—I am glad you are against ducks in pleasure-ground waters. Wherever there are ducks or other water-fowl there is always a kind of ugly scum of small feathery *débris* that gives the water a sordid and extremely unpleasant appearance.—G. JEKYLL.

The white Meadow Saffron (*Colchicum speciosum album*).—This is the fairest flower of the week facing the storms of early October, only asking for a little shelter and a carpet to sit on. I have not got it quite happy as to place as yet, the best in effect nestling on a tuft of the dwarf Lavender. There should be a soft Mossy carpet over the ground in which it grows to prevent the effects of heavy rain on bare earth.—W.

Brilliant Toadstools.—Last week, when visiting a friend at Woking, whose garden includes a bit of Pine wood, I was struck with a large patch of brilliant Toadstools. They were each 6 inches or 7 inches across, of a vivid scarlet hue above with white spots, and made a very bright splash of colour. It is quite a common Toadstool in Pine woods, but I have never before realised how beautiful a large patch of it could be.—N. L.

Gaillardias.—One is, at times, asked to recommend a hardy plant which will succeed in a semi-dry position, such as on a sloping bank or similar place. Under such circumstances no one can go wrong in planting Gaillardias freely. There are not many plants that will give such a good return, and, apart altogether from their value in dry situations, the flowers are very useful when cut. Plant about the middle of October and give them a chance to get established before winter sets in.—KIRK.

Iris reticulata in Suffolk.—I saw a country cottage garden in Suffolk recently where this Iris grows like a weed and flowers freely every spring. I was told that a single bulb had been given to the cottager some years ago, and it had increased so rapidly that there were now hundreds. A large number had been dug up for removal, and they were as sound and healthy as possible. No special care was taken with them, but evidently the soil, which was light and sandy, suited them well.—W. O.

Erigeron "Asa Gray."—This rather quaint-coloured flower, which was given an Award of Merit by the Royal Horticultural Society, is praised in catalogues, but it does not strike me as very effective. The colour of the blossoms is variously

described as "apricot-yellow" or "buff-yellow," but it is not at all a clear colour, the tone being somewhat "muddy." It is a vigorous grower and quite a change from the usual mauve tints of the family, and is, moreover, very free-flowering. It is still blooming freely with me in my North London garden.—W. O.

Kniphofia Nelsoni.—It is often alleged, and with a certain amount of truth, that the Torch Lilies are clumsy and ungraceful plants. These faults cannot be charged against *K. Nelsoni*, which may be truthfully described as of elegant habit and quite devoid of clumsiness. Its foliage, too, is graceful and free from the heaviness of that of some of the Torch Lilies, while its bright spikes are always appreciated. *K. Nelsoni* flowers at the same time as the Michaelmas Daisies, Sun-flowers, and similar things.—KIRK.

The Violet Cress (*Ionopsidium acaule*).—This, like other annual flowers, is often forgotten, from, perhaps, not going well with other annual flowers. It is best treated in a different way. Last winter a bed was covered with it, lasting in flower till summer, when it began to fade. Instead of removing it I let the plants seed, with the result that now there is a close bed of self-sown plants quite fresh when most flowers are fading. A pinch of seed on a gravelly spot will sometimes thrive and renew itself for years.—W.

Cyclamen neapolitanum.—This, just opening its lovely rosy-pink and white flowers, looks very dainty in a shady part of the rock garden. The white form is charming and is flowering as profusely as the pink. Planted in leaf-mould with some old mortar-rubble incorporated in the soil, in a well-drained position where they are shaded by trees, they do very well in my North London garden, the marbled leaves almost as attractive as the flowers. With old corms I think it is a good plan to plant them obliquely, as there is often a hollow at the top of the corm, and, planted thus, there is no chance of water collecting in the hollow and rotting the corm.—N. L.

Hedges.—The prevalence of hedges and fences in Britain struck a Belgian friend now in England as a waste of land, etc. He said there were almost none in Belgium. He agreed with me that hedges were, to a certain extent, picturesque, and I pointed out to him that without them we should be so windswept as to be able to grow little but common vegetables. I certainly think that, despite certain drawbacks, our hedges are useful. He thought that, on the whole, the Belgian country

worker was in a happier economic position than ours, and I should say that he is right in this respect, but I hope that whatever changes we may make in our country we shall always retain our hedges and all the wildness that still remain to us, even if they do not pay.—W. J. FARMER.

Starworts.—Of the plants useful in the autumn for the hardy flower garden there are very few that can equal the Starworts, about the more select of which there is a quiet beauty which is charming in the waning days of the year. The variety of colour, form, and bud is delightful, one great point in their favour being that they are regardless of cold and wet. Less showy, may be, than the early-flowering Chrysanthemums, they are, we think, more refined in colour and form. The great thing is to get the distinct kinds, there being so many with little character or value.

Chrysanthemum Cranford White.—This, I think, is one of the best of all the dwarf forms. In my garden, in an aspect facing south, it has reached a height of not more than 15 inches. Its flowers are white with a slight yellow-green in the centre. The petals are tinged with pink when the buds are nearly open, but this fades. The chief point in its favour is its long blooming season. In my garden it started blooming about the middle of July, and has not ceased since. It is about at its best now (September 27th), and there is a prospect of it continuing for some weeks, since many more buds are being produced. It was planted out in April in a well-manured plot, and has had nothing but ordinary care.—E. T. ELLIS, *Weetwood, Ecclesall, Sheffield.*

Clematis Campanile.—Messrs. G. Paul and Son staged this good novelty before the Royal Horticultural Society on September 26th last, when an Award of Merit was granted it. This, according to M. Lemoine, raised from seeds saved on *C. grata* without any artificial cross, is herbaceous, attaining only some 3 feet or so high, and in this way suggestive of *C. Davidiana*. The flowers are produced in erectly-disposed pyramids. Tubular in the bud, pale blue with violet-coloured mouth, and each about $\frac{3}{4}$ inch long, they presently open, and the sepals, recurving, present pretty shades of light and dark blue which, with the clusters of creamy-coloured anthers, are singularly effective as a whole. For so distinct a novelty, appearing thus late in the season, there is abundant room, whether in the border or occasionally in thoughtfully-selected posi-

tions in the rock garden. The newcomer, too, has the good attribute of fragrance, though it claims attention by colour-effect alone.—E. H. JENKINS.

Sedum spectabile.—I think the old pink form is prettier than the deeper-coloured ones, a large patch in full flower being effective now in the rock garden. I think one of the great charms of this species when in flower is that it is such an attraction to the big autumn butterflies, particularly the brilliant Red Admiral and the Peacock. On a sunny day there is almost sure to be one or more of these beautiful insects on the flowers. This *Sedum* is not content with the dry, poor soil which satisfies, or even is necessary for, so many of its relatives, but likes a good loam, not too dry.—N. L.

Questionable advice.—I read with interest the note of "In Doubt," at page 476, on "Economy in the Garden"—the pamphlet of the Royal Horticultural Society. In respect of the advice given to sow Cabbages where they are to grow, those who want a few thousands of early heads would find that the price of the seed would be far beyond the value of the Cabbages. Further, it would involve the waste of all the thinnings. The advice may be all very well for those who wish to grow about fifty heads, but, even so, I have my doubts as to the "economy" of the proceeding. Much of the advice given in the pamphlet is superfluous. Most of us know—or ought to know—all the everyday "tips" given by the writer of the pamphlet. Whether we agree with them is another matter. If it is permissible to criticise such an august body as the Royal Horticultural Society it may be remarked that the Society might have economised by suppressing the pamphlet in question, thus effecting a saving alike of paper and the cost of printing.—Scot.

The broad-leaved Spindle-tree (*Euonymus latifolius*).—There is a distinct beauty about this deciduous European kind just now where, fruiting with any measure of freedom, its fruits also remain untouched by birds. Not all its attractiveness is, however, due to the fruits alone; the fleshy, five-parted capsules, rose-scarlet in colour, on pendent, wiry pedicels are equally showy and of an unusual tone of colour among shrubs. Dangling elegantly in pairs or more from the leaf axils on sufficiently long foot-stalks as to hang clear of the bronzing leafage, they afford, in conjunction with the bright orange fruits, an unusual attraction. The plant is worth grouping in shrubbery border or in beds alone. Not usually fruiting with great freedom, artificial pollination might profitably be indulged in when the plant is in flower. Recently I saw it planted near the margin of a lake, where in mid-September it was all but leafless and bearing but one or two fruit clusters on a 6 feet high plant. In all probability the soil conditions were too wet for it. In well-drained loam in the same garden the plant was far more happy.—E. H. J.

Clerodendron trichotomum in Scotland.—This fine shrub is not often to be seen in Scottish gardens, though it is quite hardy. Probably the reason is that, when young, it is so fully occupied in forming fresh growth that the flowers appear too late in the season to be of much account. But old bushes behave more satisfactorily. One of the most attractive objects in the garden here just now (September 30th) is a plant of this *Clerodendron* fifteen years old, 8 feet high, and 12 feet through, spangled with white star-like blossoms set in ruddy bracts. The flowers are delightfully fragrant, and the leaves, when

crushed, emit the same odour as our native Gladdon (*Iris fetidissima*), that of cold roast beef. It is one of the few late-flowering shrubs that will flourish in London. I was first attracted to it by the beauty of a shrub in the garden of Hans Place. In London, moreover, it flowers in August, a full month earlier than it does in our latitude.—HERBERT MAXWELL, *Monreith*.

Fallugia paradoxa.—This is a very interesting and ornamental shrub with white flowers, somewhat like those of *Potentilla*. It is a native of New Mexico, Nevada, and other countries, and was originally introduced to the British Isles about 1877. Under cultivation it grows about 4 feet high, forming a dense mass of slender, greyish branches clothed with tiny, deeply-lobed leaves that are grey-green above and silvery beneath. The flowers are produced during the greater part of the summer, a few appearing in early autumn. Each one is about 1 inch across, white, with a central mass of yellow stamens. Unfortunately it is not very hardy, and except in the most favoured parts of the British Isles must be grown against a wall with a south or west aspect. When selecting a position care should be taken that the soil is well drained and that the plant is exposed to full sun, for it is essentially a sun-loving shrub. Light loamy soil is suitable for it, and cuttings can be rooted in a close frame during summer.—D.

Roses with attractive fruits.—What is usually one of the more interesting and uncommon classes arranged by the National Rose Society at its autumn show is that for a collection of Rose hips and which serves to demonstrate that the Society is alive to any form of beauty or ornament of which the Rose is capable. The hips produced by *Rosa rugosa* and several of its forms are well known for their size and decorative character in autumn, and which, in conjunction with handsome leafage, show to considerable advantage. There are, however, several others, and among them some of the newer species from China deserve notice. Two, *R. Moyesi* and *R. Fargesii*, were conspicuous in Mr. Allgrove's first prize lot, the former having scarlet-coloured hips nearly 3 inches long and highly attractive. Those of *R. Fargesii* are even more brilliant, the fruits softly spiny. A third, which may or may not be Chinese, is *R. setipoda*, the hips being shorter than in the others named. All three, however, are brilliant in colour, and, with characteristically ventricose fruits—*i.e.*, large and globular at the stalk end and contracted near the mouth—are as distinct as they are ornamental. All three have the pinnate leafage of *Rosa Moyesi* and are worth cultivating because of a fruit beauty and brilliancy which remain well into the autumn.—E. H. JENKINS.

Pretty flower effects in bowl or vase.—This title is suggested by an oblong glass dish filled with moderately long sprays of *Erica vulgaris* Alporti, *E. v. Hammondii*, and *E. vagans rubra*, from out of which three handsome blooms of *Rose Caroline Testout* on nearly foot-long stems appear. The *Rose* has quite a rich tone—that fuller pink which apparently is its more frequent endowment in autumn than at other times and for which the Heaths named—flower and foliage—make a most agreeable setting. No other foliage is used and none is required. From the ends of the boat-shaped dish the reddish-coloured *Erica Alporti* extends, the other two occupying the central part. The Heaths are not heavily flowered—it is, indeed, a little late for these two now to be seen at their best—and this might prove a gain. The charm

of it all, however, lies in the happy commingling of the Heaths with which the *Roses* harmonise in a most pleasing manner. A tall vase filled with the same *Rose*, having light sprays of *Pittosporum nigrum* as garniture, is also effective and good.—E. H. JENKINS.

Eucryphia cordifolia in South-West Scotland.—Sir Herbert Maxwell has kindly sent me a spray of this *Eucryphia*, which I saw in the month of June when I was at *Monreith*. It is flowering well at *Monreith* this year, and must be very handsome with its fine glossy leaves and large white flowers. I believe that it is not quite so hardy as *E. pinnatifolia*, of which there are now a few good plants in the south-west of Scotland. *E. cordifolia* has not yet found its way into many gardens in the district, but Sir Herbert Maxwell's success will, doubtless, induce others to attempt it in this favoured part of Scotland. It is a great pleasure to see *E. cordifolia* in bloom from this part of Scotland, and so charming a shrub or small tree ought to be better known.—S. ARNOTT.

Dianthus aridus.—By some this has been considered as synonymous with *D. Knappi*, but whether distinct species or not, they are certainly distinct enough as garden plants, more particularly in colour. Indeed, in this respect it may briefly be referred to as a sulphur-coloured *D. Knappi*, the latter, when compared with it, being of a decidedly deeper tone of yellow. Less showy than the dwarf-growing members of the race, the above-named are interesting late in the season. Of erect habit and growing 18 inches or so high, the position best suited to them is a slightly raised one in the rock garden, so that they do not get above the line of vision. A soil freely mingled with sand or old mortar rubble, with good drainage suits them well. Easily reproduced from seeds, there is little difficulty in keeping up a stock, if this is indulged in periodically, for, though of perennial duration and in rock or wall crevice or the like going on for three or four years without giving any sign of impaired vitality, an exceptionally good flowering may produce this at any time. Grown in richer soils, *D. Knappi*, to which the above is obviously nearly related, frequently suffers after a profuse flowering.—E. H. J.

Colchicum speciosum album.—It is just sixteen years ago that this was shown before the Royal Horticultural Society by Mr. J. Hudson, Gunnersbury House, and gained a first-class certificate. Probably no recent hardy plant novelty has more thoroughly deserved that honour. Hardiness, vigour, and freedom of flowering are chief among many good attributes, and whether in the Grass or the richer border soils it appears equally happy. Some growers say it is more vigorous and free than any other form of the species, though this does well in light and medium loams generally. At East Burnham Park Sir Harry Veitch has it planted with much success in the Grass, where it does uncommonly well. Indeed, on single bulbs (corms) three years' planted I counted a year ago a dozen flowers, the pure white cups erect and self-supporting—another good attribute of a fine plant. The soil is moderately light and stony. The plant is now so reasonable in price that it is possible to employ it with some freedom in Grass gardening, and if, as the excellence of the subject merits, it is planted in prepared positions, so much the better. Though the orthodox planting season has passed, the plant is of so accommodating a nature that it may be dealt with for some time to come.—E. H. JENKINS.

TREES AND SHRUBS.

RHODODENDRON GAUNTLETTI.

This is a supposed hybrid, but what the parents are no one seems to know. One of its parents is evidently *R. Griffithianum*, better known as *R. Aucklandi*. The large flowers, which often each measure over 4 inches across, are of a pale flesh colour when they first open, eventually changing to pure white. As many as nine blooms are often borne on a single truss. A large bush is a beautiful sight when in full bloom. Though it is such an ornamental variety it is apparently little known, and is not often met with. It makes a fine contrast to the crimson-flowered sorts as *R. barbatum*, *R. Thompsoni*, *R. Shilsoni*, and the dark-flowered forms of *R. arboreum*.

HARDY FUCHSIAS.

DURING the latter part of the summer and for a good while in the autumn, should

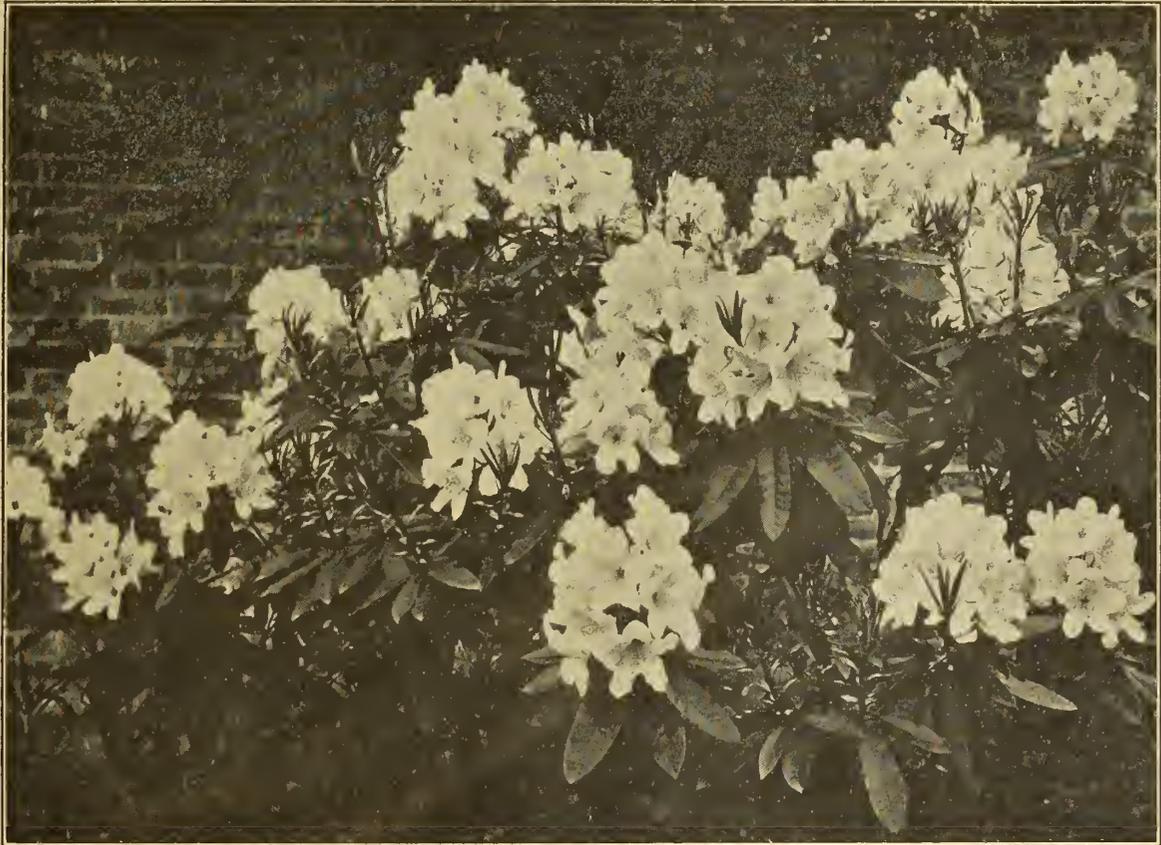

of a small tree. In colder districts these Fuchsias may be treated as herbaceous subjects, that is, cut to the ground in the winter, when the roots can be protected with a few leaves, which will render them perfectly safe. Plants so treated will throw up shoots which will, under favourable conditions, attain a height of 4 feet to 6 feet in one season, and yield a wealth of blossom. A hardy variety quite different from any of the others is *F. corallina*, often known as *F. exoniensis*. This is of a more spreading habit than either of the two preceding, forming as it mostly does a spreading bush whose arching shoots are clothed with larger leaves than those of the preceding. The flowers, too, are more suggestive of some of the greenhouse kinds. From its somewhat spreading style of growth this Fuchsia is seen to advantage in an elevated position, such as in some of the larger arrangements of rockwork, especially where it is lit up by the rays of the declining sun.

GARDEN PESTS AND FRIENDS.

NOTES AND REPLIES.

Christmas Roses unhealthy.—Can you tell me what is wrong with these Christmas Roses and what to do? Before planting them the soil was entirely renewed from a pasture, with good manure mixed into it. I put some Vaporite in afterwards, but the leaves almost all come up spoiled or discoloured, and I think there must be some evil influence in the soil—possibly a grub or worm. The situation is under a north wall.—M. KEEP.

[The leaves are badly attacked by the Hellebore leaf-mould fungus (*Ramularia Hellebori*). Usually the active season of the growth of the fungus is during summer, though its worst effects do not appear till later. All that can be done now is to collect and burn all the affected parts of the plants, removing and burning if possible 1 inch or so deep of the soil about the plants, which is probably full of the spores of the fungus. In spring—say

Rhododendron Gauntletti. Nymans.

the weather be favourable, the different hardy Fuchsias form a delightful feature in the garden. Their merits in this respect are too often passed over, although I believe a good demand has sprung up for them within recent years. In country gardens some of the commonest and, I must say, still some of the best may be often seen. The old Fuchsia *gracilis*, which, by the way, is now regarded as a variety of *F. macrostemma*, is one of the most generally met with. In mild districts it will pass unscathed through the winter and form a good-sized bush which, when laden with its myriads of slender blossoms, forms a handsome specimen. In habit, too, it well merits the distinctive name of *gracilis*. Another good old kind of which large specimens may be seen in various places along the sea coast is *Riccartoni*, a stiffer and larger grower than *gracilis*; indeed, in favourable localities, it will almost attain the dimensions

The list of varieties of hardy Fuchsias is now a long one, a good many seedlings having been raised within recent years, but some, probably owing to the influence of tender kinds, are not so hardy as the old and well-tried ones. When such as *gracilis* or *Riccartoni* are planted in a good-sized bed, *Hyacinthus candicans* or some of the light-flowered *Gladioli* may well be associated with them. An open loam where moderate drainage is ensured is very suitable for these Fuchsias. As with most Chilian shrubs, they delight in a liberal amount of atmospheric moisture.

K. R. W.

"The English Flower Garden and Home Grounds."—New Edition, 12th, revised, with descriptions of all the best plants, trees, and shrubs, their culture and arrangement, illustrated on wood. Cloth, medium 8vo, 15s.; post free, 15s. 6d. Of all Booksellers or from the office of GARDENING ILLUSTRATED, 63, Lincoln's Inn Fields, London, W.C.

about May—periodical syringing with sulphide of potassium should be started, and if kept up at intervals of two or three weeks for some time would doubtless keep the fungus at bay. One ounce of the sulphide to two gallons of rain water will be strong enough, and care should be exercised to wet all parts of the plant, the under as well as the upper surfaces of the leaves. Prior to adding fresh soil to replace that removed, a dusting of air-slaked lime should be given.]

Orange-fungus on Roses.—I would be very much obliged if I could be informed what is the blight which is affecting my Roses and if there is any cure. I send a few specimen leaves. This blight has only appeared during the last month or so, and has rapidly spread, even amongst Rose bushes just planted.—M. COURTNEY.

[The leaves you send have been attacked by the red or Orange-rust (*Pragmidium subcorticium*), which appears first on the

leaves in orange, powdery patches. These in time become darker, owing to the formation of the second kind of spores, which are dark brown, the third kind being produced later and forming small black dots on the undersides of the leaves. In this state the fungus passes the winter; the spores form these black dots, infecting the young leaves the following spring. It is very essential when the leaves fall in the autumn that they should be collected and burned, and plants that have been attacked should, in the spring before the buds open, be thoroughly wetted with 2 oz. of sulphate of copper dissolved in 3 gallons of water. If the disease still shows itself spray with weak Bordeaux mixture and pick off the infested leaves.]

FRUIT.

GRAPES AND GRAPE VINES IN AUTUMN.

A LITTLE fire-heat is absolutely essential in the case of Muscats, Lady Downes' Seedling and Gros Colman in the autumn. It prevents the undue decay of the berries and improves the flavour, especially if the ventilation is well attended to. Advantage should be taken of every bright, calm day in autumn to get the atmosphere as buoyant as possible by ventilating more, and, at the same time, keeping the pipes warm. It is never necessary to have the pipes very warm, and, in the case of the variety Alicante, dangerous to have them so, as much heat causes the berries to decay. Where there are pot plants in the vinery at this season all needful watering of such must be done about 10 o'clock in the forenoon, taking care not to spill any water about the house. The moment a decaying berry is observed cut it out, as, if left, it will cause the decay of many more. The bunches of Muscat of Alexandria should be fully exposed to all sunshine, as there will not be much danger from burning now.

The early varieties, from which the Grapes have been cut, should be treated as carefully as the others. Ripeness of wood is an important matter, and to secure this, ample ventilation is essential at both the top and front of the structure. The ends of the bunch-bearing shoots may be cut off now if a length of about 14 inches from the base can be left, the final pruning being done when the leaves have fallen naturally. Do not neglect the borders. If the soil is approaching dryness—as it will in the case of inside borders—give a thorough watering, repeating if need be.

BOURNE VALE.

THE COMPOST YARD.

WHERE much renovation of fruit borders or top-dressing of the same is contemplated the stock of material for the carrying out of the same should, if at all depleted, be replenished before the work is commenced. This will avert any delay occurring, a most important consideration when the roots of Vines or fruit-trees, as the case may be, are already out of the soil and cannot, owing to a shortage of compost, be properly laid out or replanted. Loam is, of course, the principal and most important of the various ingredients required for work of the above-named description, and a good stock of the best procurable in each individual instance should be carefully stacked both for present and future requirements. For border renovation this may be used in a fresh condition or just as it is carted in. Burnt soil is another necessary ingredient, especially when heavy soils have to be dealt with. This generally consists of the

residue left over after burning a quantity of garden refuse. Very heavy clayey soil and clay itself are oftentimes burnt for the same purpose when the before-mentioned material is not available. Wood-ashes are a valuable asset and should be kept in the dry after hedge trimmings and refuse wood gathered up after gales have been burnt or charred. An abundance of drainage material, such as brick-bats, clinkers, stones, or coarse gravel, should also be kept in readiness to avoid loss of time in cleaning the old when removed from the base of the border. Drain-pipes in two or three sizes should be stocked, while, if necessary to concrete the base of the border, the various requisite ingredients for doing so should be ready to hand. Horn shavings, hoof parings, $\frac{1}{2}$ -inch bones, bone-meal, soot, air-slaked lime, and lime rubbish, all of which must be kept in the dry, are a few other necessary and important materials required for enriching, and, in the last-named instances, making good any deficiencies when lime is lacking in the soil used for forming the compost.

THE LOGANBERRY.

THE Loganberry has become one of the established fruits of the garden, generally speaking, but it cannot be said that it is a success everywhere. The Raspberry has the same variable character. In my own case it is absolutely impossible to maintain full-bearing rows of Raspberries without periodical removal to fresh sites. Unless this is done debility is set up and the plants dwindle away. This does not, of course, happen exactly in the same way with Loganberries, because it is a common experience to find a tendency to excess of vigour on the summer growth, the hopes that may very reasonably be set up by this summer vigour being dashed to the ground when the fruiting season arrives. So disappointing has the open trellis system of growing Loganberries proved with me that I have now grubbed them out. While this has been my experience for several seasons I have envied the fine crops of large berries that I have seen in some other gardens and to which no more attention had been paid than to my own. In one small garden I visited this summer Loganberries had been substituted for Raspberries because these latter had failed, while the Loganberries had borne heavy crops.

The cause of the failure with Loganberries seems to be due to the presence of an insect which deposits its egg in the embryo shoot in the early weeks of the year. The larva burrowing into the shoot causes its collapse, consequently, there is no fruit except on straggling shoots which may happen to have been missed. Raspberries are found to be similarly infested by it. I have observed how well in some gardens Loganberries will fruit when trained to walls, and though I have not seen them thus trained, it is said they can be adapted to narrow arches in Rambler Rose fashion. The great vigour of the root stock and the thicket of growth that springs up from the base would suggest that unless thinning and tying are attended to there would be neither pleasure nor profit in growing them on a trellis. I saw the common Blackberry in Mr. Crook's garden at Camberley as fine in fruit as the much-boomed Lowberry a few years since, but the spiny canes made one shrink from growing them in the garden, fine as was the crop. W. STRUGNELL.

[The pest to which our correspondent refers is, no doubt, the Raspberry moth, to a description and a preventive of which we hope to devote an article in an early issue.—Ed.]

ROOT-PRUNING.

I HAVE just had the pleasure of an afternoon with a Belgian gentleman who comes of a famous gardening family, and he told me that he does not believe in root-pruning, and disapproves of restricting the growth of fruit-trees. He admitted that in the case of wall-trees it was essential, but for orchard or garden he believed in allowing fruit-trees to grow almost as they pleased, merely doing a little thinning-out of the branches. On a large scale he was convinced that too much pruning did not pay, and that it was better to devote the time to spraying the trees. He said he considered cordons quite the wrong method of growing fruit-trees, and also that it was wrong, or, at any rate, commercially and naturally unsound, to try to train trees with every branch a cordon. I have lately been coming round to this point of view. The single cordon in good soil grows so vigorously that it requires an infinite amount of labour to prune it and keep it in bounds, and unless one has a very tiny garden only, and wishes to grow a great variety in a small space, I would do all in my power to persuade others to have nothing to do with single cordons unless on walls. My friend would plant strong-growing varieties 30 feet apart on the Crab and prune them very little. Of course, circumstances may make other methods desirable with some, but in the long run the more natural method would pay the best in quality and fertility, I believe. I should like to hear what others have to say on this matter.

Redruth, Cornwall.

W. J. FARMER.

NOTES AND REPLIES.

Treatment of Apple-trees.—Bush Apples planted last autumn had shoots all shortened by removing upper third. A friend says that they require further shortening. Is this so? There was plenty of bloom, but very little fruit, fortunately, this season. The shoots appear well furnished with fruit-buds for next year.—N. E. W.

[It all depends on the age of the trees. If young and vigorous, shortening the leaders on main and subsidiary branches to the extent you have done will suffice, and nothing further in this direction is needed this winter. Side shoots should, however, be shortened to four buds to form the foundation of fruiting spurs. With respect to trees which are nearly or fully established, all shoots except those at the extremities of the branches should be shortened to four buds either in this or the succeeding month. The leaders may be left 5 inches or 6 inches long. It is a good thing the trees failed to fruit, as nothing tends to cripple newly-planted trees more than premature fruiting.]

Fruit-trees for north-east wall.—Can you suggest two or three Pears (cordons) for north-east wall in Vale of Evesham? If not Pears, Apples or other fruit-trees. I already have Jargonelle on another wall.—N. E. W.

[We fear you would not find Pears do well on such an aspect. Why not try Plumus, such as Coe's Golden Drop, Ickworth Imperatrice, and President or Late Orange, all of which would succeed on a wall facing north-east? Cherries, such as May Duke, Late Duke, or Waterloo, would also answer. If anxious to have Pears, select Louise Bonne of Jersey, Beurré Hardy, and Marie Louise d'Uccle.]

Propagating Currants and Gooseberries.—In view of the diseases which, nowadays, are apt to be imported through the medium of bought-in plants, it is advisable that, where practicable, young stock be raised at home from clean bushes. The strong summer growths of Gooseberries and of Currants make excellent cuttings. The best time to deal with

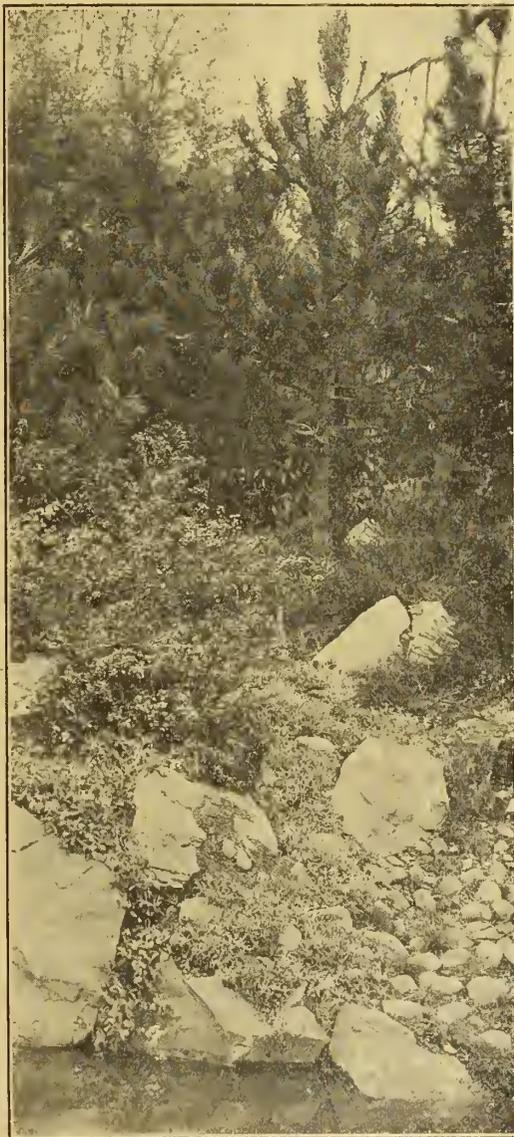

them is immediately after the foliage drops. In making cuttings the base of each should be cleanly cut across just below a bud. In the case of Gooseberries, all the buds ought to be rubbed out from the base upward to the fourth from the top. As regards Black Currants, all the buds may be left, treating Red Currants similarly to Gooseberries. Let the cuttings be from 12 inches to 14 inches in length. Take out a notch with the spade about 8 inches deep, put in 1 inch or 2 inches of sharp sand, placing the cuttings thickly on the latter. Fill up, and make very firm, and the greater part of the cuttings will succeed.—Kirk.

Grapes failing.—I should be grateful to you for advice as to treatment of Vines which have gradually deteriorated year by year for the past six or seven years. Before that my Grapes were noted. I have a large vinery, but lately I use no heat in winter; in fact, living by the sea, we get little frost, and have not thought it necessary. The border outside has a thick line of Belladonna Lilies against the wall. These have increased very much, and it is possible they are robbing the Vines. I intend to reduce them this winter, but should be obliged if you would tell me what sort of manure to apply to the roots and how deep I ought to dig, probably any time now would be suitable. The Grapes are small, and the bunches small, and this year most of them have shanked, even a young Vine, Muscat Hamburg, only planted two years.—CECILIA GEORGE.

[From the description given as to the condition of the Vines in question there is but one remedy, and that is to lift the roots and replant them in an entirely new border. In future we advise you to grow nothing whatever on the border, but to let it be for the roots of the Vines alone. No greater mistake can be made than devoting the surface of Vine borders to other purposes than for which they are intended, and, if insisted on, the Vines invariably suffer and eventually come to grief. Your suggestion as to applying manure and digging it in would but add fuel to the fire, as the effect of the manure, combined with the destruction of the roots, would cause the Grapes to shank still more. Manure should never be applied in the manner suggested, and digging, as is generally understood by the term, should never be attempted. The only approach to digging that is permissible is in spring, when applying an artificially-compounded Vine manure, and in autumn when top-dressing the border. Even then the surface should, at the most, be broken up no deeper than 3 inches, using for the purpose a digging-fork only.]

Enemies of Currants.—The enemies of Red and White Currants do not produce such disastrous effects as in the case of the Black Currant with its big bud, although aphid, and in some seasons red spider, are rather troublesome. In some districts the foliage is affected with a kind of spot or black mildew, causing it to drop prematurely, and although the fruit is not affected to any great extent, it has a tendency to lead to premature ripening, with the result that the berries are neither

so large nor sweet as under more favourable conditions. I used to think that this visitation was due entirely to atmospheric influence, but this is not altogether the case, or, rather, there are certain conditions under which the trees are much more susceptible to attack. I noticed this season, for instance, two plantations not very far apart, the one very old and rather neglected and the other of young, vigorous bushes. The old plants were practically denuded of foliage quite early in the season, while the leaves of the younger plants were only occasionally spotted. The remedy is obvious, *i.e.*, young plantations kept in a healthy-growing state.

A rocky bank in Mrs. Greer's garden at Curragh Grange, Co. Kildare.

Until these can be raised it is advisable to spray older trees fairly early in the season with one of the preparations recommended for preventing and arresting fungoid growths. When starting a new plantation the cuttings should be obtained from a healthy stock, this being specially important in the case of Black Currants, the "big bud" in their case leading to such disastrous results and being so difficult to eradicate. It is fortunate that it is confined to certain districts, there being many places where it is practically unknown.—E. B. S., *Hardwick*.

Planting.—Where vacancies are to be made good by lifting and transferring trees from

one part of the garden to another, the work may be commenced now. If carried out promptly far better results follow than when it is postponed till later in the season, as the trees then become partly re-established before winter sets in. If trees have to be purchased and sent from a distance, preparation for the planting may then be carried on as opportunity offers, there being less need for hurrying matters in this case, as actual planting cannot at the earliest be done until November. Bush fruits, which are to be had earlier than fruit-trees, may be planted during October, therefore, if the planting of new quarters is contemplated and the bushes for the same have to be purchased, the holes should be dug in readiness. If there is a reserve of bushes on the spot to draw from, lifting and transplanting may go forward at once.—A. W.

Fruit stock trials in Kent.—You may be interested to hear we are doing fruit stock experiments at the Malling Experiment Station (under Wye College).—E. A. B.

PLANTS AND FLOWERS.

ROCK, ALPINE, BOG, FERN, AND WATER GARDENS.

A ROCKY BANK.

The illustration shows part of a rocky bank in Mrs. Greer's garden at Curragh Grange, Co. Kildare. This bank runs down into water which catches the reflection of the stones above.

R. H. BEAMISH.

NOTES AND REPLIES.

Newly-planted alpiners after frost.

Many people plant rock plants too late in the season—either from necessity or choice—these requiring careful attention after frost. In many cases it will be found that the plants are partially lifted out of the ground by the frost. Little can be done to them while this lasts, but I have found that small specimens which may have their roots exposed are all the better for having a little dry soil or sand put over them and brought up to the necks of the plants. As soon as a thaw occurs they may be pressed gently down into their proper position. By attention to these little points many small rock plants which would otherwise be lost have a good chance to pull through and start into growth in the spring.—S. ARNOTT.

Airing rock plants in frames.—Many alpiners in frames are lost in winter through keeping them too close, with the result that they damp off badly. They suffer more from damp than from cold, and a free circulation of air should always be allowed. If the sashes are slightly raised this will be sufficient. An ideal frame for wintering rock plants is one which can be ventilated by side or end ventilators just a little above the level of the plants. The plants should be plunged in sand or ashes. Some people keep their rock plants close during severe frosts, but if the plants are dry overhead air is very beneficial.—S. A.

Viola calcarata Papilio alba.—I had some plants of this sent to me in the spring, and have been charmed with them. They are as free-flowering as the typical *Papilio*, and quite as easy to grow. Like it, too, they ripen plenty of seed, and sow thousands about, but they are so dainty that they are welcome anywhere. They have been flowering all the summer, and are still in bloom. The seed-pods of *Violas* must be picked while still green, as they seem to open and throw their seeds out all of a sudden.—N. L.

Carlina acaulis.—This looks very pretty grown in a retaining wall in a hot, sunny position, the curious "everlasting" flowers being handsome among the green spiny foliage. It is allied to our native *Carlina Thistle*, and, like it, the flowers have the habit of expanding in dry weather and closing when it is damp, retaining this property for quite a long time. It needs a dry, poor, sandy soil. It is quite worth growing, and is a contrast to the majority of rock plants. It comes readily from seed.—J. W. O.

VEGETABLES.

PARSLEY FOR WINTER USE.

IN some gardens Parsley always winters badly outdoors, no matter how much care may be bestowed upon it in the shape of affording protection with mats or tanned canvas covers laid on a rough framework, or long rods arched over the beds, and having both ends inserted in the soil. In such cases the precaution should be taken to fill a frame or cold pit at the present time with plants raised from a sowing made in the early part of July. If nice, rich, friable compost is employed as a rooting medium the plants quickly become well rooted, and are soon established. Once the plants begin to recover from being transplanted, the lights should be drawn off, and the plants should be encouraged to make as hardy a growth as possible. The lights need only be used in the event of sharp frost occurring, or when the weather is very wet or snow-storms are expected. In the last two contingencies the plants may receive the requisite amount of air by tilting the lights at the back. Care must, of necessity, be taken to see that the plants receive all the root-moisture they require, but at the same time over-watering must be guarded against, otherwise rotting and cankering at the collar will result. Grown on these lines, a frame filled with plants standing 6 inches apart now will furnish a quantity of pickings all through the winter, or whenever the weather is too severe to allow of the outdoor plants being interfered with. When the time arrives for the frame or pit to be required for something of a more urgent nature the Parsley plants may be lifted and planted outdoors in a sheltered situation should those which have wintered outdoors be in such a condition as to render it unwise to destroy them altogether. When the demand is not so extensive as to require a pit or frame being set apart for the accommodation of the plants the case can be met by filling a few boxes some 6 inches or 9 inches in depth, or a suitable number, of large flower-pots, with some good-sized plants. These, being portable, they can, on the approach of hard weather, be accommodated in an orchard-house, or any structure from which severe frost is merely excluded. Failing this, a cold pit matted over at night would answer.

All this may appear very unnecessary to many, but as Parsley is in daily demand in so many establishments, and has, moreover, to be forthcoming, this is the simplest way out of the difficulty when either the nature of the soil or situation renders the wintering of it so uncertain that to place dependence on it doing so is a sure means of courting trouble and annoyance.

NOTES AND REPLIES.

Treatment of kitchen-garden soil.—I live in Hants, and have a poor soil—sand, peat, and large stones. In my kitchen garden the Cabbages get clubbed, also roots do not do, but Peas and Beans do well; there is no lime in the soil; it has been manured with farmyard stuff. Would a dressing of basic slag do? How much to the square yard?—ELEANOR.

[Yes, a dressing of basic slag dug into the soil where you intend growing the various crops specified next season would greatly improve its condition and render it more suitable for them. As it is slow in its action the slag should be applied and dug in not later than next month. Good lime would also be beneficial. This should be applied next February. Whichever of the two you use it should be thoroughly incorporated with the soil. Of basic slag $\frac{1}{2}$ lb. per square yard could be

applied next month. Dig it in at once, then fork the plots over next February, or, say, a week or two in advance of the time you intend sowing and planting them, as the case may be.]

Forcing Rhubarb in underground quarries.—I have some large disused underground slate quarries at the back of my house; temperature from 50 degs. to 55 degs. all the year round. They are pitch dark. I am informed that Rhubarb could be grown successfully in them. Could you kindly tell me if this is so, and which is the best book to get dealing with the culture, etc.?—F. E. R.

[Yes, the underground quarries, if dry, should prove admirable places in which to force Rhubarb. If the temperature ranges between 55 degs. and 60 degs. there would be but little, if any, need to employ artificial heat in the shape of fermenting manure. A good book for you is, we think, "The Vegetable Garden," which can be had from this office, price 15s. 6d. post free.]

GARDEN FOOD.

FOOD PRODUCTION AND THE GARDEN.

DURING the past two years we have been recommended by authorities—from the Royal Horticultural Society downwards—to increase the supply of foodstuffs in the garden. Admittedly, the advice is good; but let us look a little more closely into the recommendation—that is, from the point of view of the average private gardener. When the outcry for more vegetable production began, many, both employers and gardeners, rushed to extremes. Flower beds and borders were ruthlessly sacrificed, the usual work was upset or disorganised, the soil did not get a necessary rest, and with what result? In the ordinary course of matters, a gardener knows, or, at least, ought to know, the approximate quantity of vegetables consumed by the establishment throughout the season. Even with only the usual supplies available, there is generally more or less waste. There must at times be, as in the case when Peas or Cauliflowers—even Cabbages—turn in more rapidly than they can be consumed. Now, in the case of over-planting, merely for increasing the production, I submit that the waste will be inconceivably greater, and that, therefore, the increased planting is not justified. Two objections may be taken to this statement. Firstly, it may be said, superfluous supplies can be given to those in the neighbourhood who are not so well off. That objection fails, because practically every workman in country places has his own garden or allotment, and has sufficient supplies of his own; and even were that not the case, wherein lies the economy of over-cropping the ground and of harassing an already-over-worked and under-handed gardener, quite sufficiently worried to keep things going? The second objection which may be taken is: Why not send superfluous vegetables to training camps or to the Fleet? Let it be freely admitted that they could not be put to a better use. There arises, however, the question of transport. Take the case of a place sixteen miles from the nearest railway station, and in which all the available horses were requisitioned on the outbreak of hostilities, and which it has been found impossible to replace. Now, owing to the petrol restrictions, motor traction is out of the question. How, then, are these spare vegetables to be forwarded? As a matter of fact, an offer of such was made to a local committee, on condition that they were collected; but the same reason which prevented the vegetables from

being sent to the collecting depôt prevented the committee from coming for them. Therefore, they were wasted. The point need not be elaborated. Then there is another aspect of the matter. Increased production means increased labour. All our young men are now in the Army or the Navy. Casual labour is at a premium. How, then, can the output of the garden be increased? Let us be consistent.

A SCOTTISH GARDENER.

HODGE-PODGE.

WHEN the war broke out a French officer began the study of English with such ardour that he soon felt confident that he could converse freely with the allies of his country. One day, with an English officer, he chanced to visit a company kitchen belonging to a Highland regiment just as the cook was compounding a savory stew of the sort known in his native land as hodge-podge.

"What is it you cook, *mon ami*?" he inquired.

"'Odegpodge, sir," was the reply.

"'Odegpodge? 'Odegpodge? I know it not. Tell me, then, how is it made?"

"Why," said Sandy, readily, "there's mutton intil't, and Turnips intil't, and Carrots intil't, and—"

"But yes, so I see," assented the Frenchman, puzzled. "The vegetables, yes; but what is intil't?"

It was Sandy's turn to be puzzled, but he repeated with patient politeness—

"There's mutton intil't, and Turnips intil't, and—"

"*Oui, certainement!* But intil't—what is intil't?"

Sandy flourished his long spoon with a gesture of helpless despair.

"Am I na juist tellin' ye, sir, what's intil't? There's mutton intil't, and—"

But just then the English officer stopped laughing to explain that "intil't," although not to be found in the dictionary, was a perfectly good Scottish abbreviation for "into it" or "in it"; it was not an ingredient.

"In your so-expressive idiom, then," said the amiable Frenchman, joining the laugh, "I put my foot intil't, did I not? I who thought it was a seasoning! Not yet, alas! do I comprehend fully the English language!"

NOTES AND REPLIES.

Blanching Celery.—Labour is so scarce now that means of dispensing with it are worth attention. The Americans, or one firm in Pennsylvania, are said to carry out a system of blanching of which we hope to give some account later on. MM. Vilmorin write us from Paris:—

One of those most generally used consists in pulling up the plants with a good ball about three weeks or one month before the time of harvest and placing them side by side in a trench from 14 inches to 16 inches deep. They are then watered copiously, and when new leaves begin to develop, showing the plants to be well established, the trench is filled up with fine, friable soil, rather dry than wet, to one-third of the height of the plants. Eight to ten days later a fresh lot of similar soil is added to the two-thirds, and in another ten days the plants are completely buried, so as to leave only the upper part of the foliage in the open air.

As some of our readers may have experienced in the effort we should be glad to hear from them. It is those with heavy, cold soils who find the ordinary way of earthing so great a labour and not always giving a good result.

OUTDOOR PLANTS.

THE BLUE LACTUCAS.

You did not see *Lactuca* (*Mulgedium*) *alpina* here. I have it, but in a very safe and far away corner, whence it cannot well escape. What you did see were *L. Plumieri*, a species that makes a large tap root and never runs, and *L. Bourgaei*, the handsome, stiff-stemmed species, which, although it seeds about more freely than I want it to, plays no pranks at the root, but is a steady stay-at-home. I am also very fond of *L. perennis*, the smaller species, so pretty in the Maritime Alps and many alpine districts, and I am trying to start *L. sonchifolia*, rather like it, but more starchy in flower. It does well

without injury. In gardens where any of the Tulip diseases appears it is, however, safer to lift it yearly. It may be planted from now until the end of November at a depth of from 2 inches to 3 inches.—S. ARNOTT.

LILIUM SPECIOSUM.

OWING to the wet, cold weather experienced in August this Lily has, in some places at least, been less effective than usual this season. With the advent of cold nights and heavy dews the flowers do not open with the same freedom as when the weather is more favourable. Even if they are less satisfactory out of doors they are very useful where the greenhouse or conservatory has to be kept gay at all seasons, as they come in at a

parts, they are sure this season to be more expensive. Owing to this it behoves one to be particularly careful of those that have flowered in pots, for they are often neglected, trusting to make up any deficiencies from freshly-imported bulbs. One noticeable thing in connection with these last is that they are later in flowering than bulbs which have been grown in this country for one season or more. By some it is considered that the bulbs must be dried off for a time after flowering, but this is a mistake, as it leads to many of the basal roots perishing and the bulb itself being greatly weakened. When the flowers are past, the pots should be stood out of doors and watered when necessary till frosts set in, when they may be removed to a frame, giving them plenty of

Lactuca Plumieri at Myddleton House.

with Mrs. Lloyd Edwards, but has not quite caught hold here yet.

E. A. BOWLES.

Tulipa Greigi.—This is a striking Tulip, and attractive even before the flowers appear. The broad leaves are prettily marbled and flaked with a good chocolate-brown on the green ground. The flowers, each sometimes as much as 8 inches across when open, are of a dazzling scarlet. Several varieties have been selected, but most of these are too high in price to recommend in these days of economy. *T. Greigi aurea*, of brilliant yellow, if dearer, is not excessively priced. Although this handsome Tulip is all the better for being lifted annually when the foliage has withered and rested until early November, it may be left in the ground for some years

time when many of the summer-flowering occupants of the greenhouse are past their best. For decoration under glass they are most useful when they are as late as possible, unless there are especial reasons for having them in flower earlier.

In order to obtain late blooms the best way is to grow them altogether outside, from the time sharp frosts are over and throughout the summer months. In potting it is very essential to put the bulbs sufficiently deep to allow of a top-dressing of good soil, when the stems lengthen and the roots form at their base. Unlike *L. longiflorum*, insect pests rarely give any trouble in the case of *L. speciosum*. In previous years, owing to the immense importations from Japan, good bulbs of *L. speciosum* have been obtainable at a very cheap rate, but, owing to restricted im-

portations, they are sure this season to be more expensive. Apart from protection from frost the lights will serve to ward off heavy rains. In the event of sharp frosts a mat or some other protection should be given to the frame. Then at any time during the winter or early spring the bulbs should be repotted in a mixture of loam, peat, or leaf-mould and sand. In potting, as much of the old soil as possible should be taken away as can be done without injury to the roots, and, on being returned to the frame, enough water should be given to keep the soil slightly moist till growth recommences, when the supply must be increased.

W. T.

Helenium autumnale "Riverton Gem."—This richly-coloured form is indispensable for the autumn border, and when grown in a large patch has a very telling effect.

The flowers are large, the petals heavily streaked and splashed with a coppery-erimson hue, making a gorgeous piece of colouring. To get the best blooms the clump should be split up every spring and the strongest crowns planted separately about a foot apart. The result is very large branching heads of fine flowers. There is a more highly-coloured form known as *H. autumnale rubrum*, but I do not think it is superior to "Riverton Gem."—J. W. O.

OURISIA COCCINEA.

ONE cannot but think, when Mr. Arnott (p. 507) refers readers of GARDENING ILLUSTRATED to Mr. Cornhill's note, which scarcely confirms his own view of the above plant, that he is content to let the matter rest on weak, inconclusive testimony. On Mr. Cornhill's own showing his experience of *Onrisia* appears to be limited to three plants, two only of which did well for a time. These, apparently, were neither lifted nor divided, hence their failure in no sense gives support to Mr. Arnott's theory that the occasional lifting, dividing, and replanting which I advised and still practise are, in some instances, wrong. Mr. Cornhill's words are: "I took several well-rooted pieces from it, and from that time it never flourished, and the young plants died." Nothing is said about "lifting and dividing," to which Mr. Arnott appears opposed, hence, not only must Mr. Cornhill's failure be looked for elsewhere, but Mr. Arnott is not justified in seeking shelter for his statement under it. Why established examples did not thrive because a few well-rooted pieces were taken from them is a little puzzling, and we are not told when, or how, it was done. The fact that the "well-rooted pieces died" also would, for these, point to some cultural error or lack of appreciation as to their precise needs.

Here it may be helpful, seeing that failures do occur, to state more clearly and emphatically than I have done before some of the essentials to success. Planting is one of them. This *Onrisia* is rhizomatous, nearly two-thirds of the extending rhizome rooting freely as it goes on. The essential in the case is that these running shoots be planted naturally, *i.e.*, horizontally-disposed, practically even with the soil. If planted erectly so that the greater portion cannot touch the soil they are bereft of support and doomed to failure. Dryness the plant abhors. A cool root-run and humid conditions it revels in. Much heat, full exposure, absence of shade, or some cooling influence, as nearby rock, are, alike, distasteful, each responsible for a meagre, restricted growth and an equally meagre flowering, or none at all. The soil conditions I have given before and will not repeat. Here, however, the plant is not very fastidious. At the moment I have some pieces in pots doing uncommonly well in sandy heath soil, which is neither ideal nor what I would use for choice. They were planted on the principle I have laid down, and at the end of a month new roots are pushing freely. There is no better sign. They have had the protection of a somewhat shaded frame and been given humid conditions throughout.

I would not have written of this plant again except for its sterling worth and beauty, and the desire to help those who have not yet succeeded with it. That it is an exceptional subject I admit. Its cultural difficulties are, however, by no means insurmountable, and those that are—and they are few—will be best overcome by a close study of the plant in conjunction with the genial conditions of its native land.

E. H. JENKINS.

THE THYRSOID BELLFLOWER (*CAMPANULA THYRSOIDEA*).

YELLOW Bellflowers are rare in the genus *Campanula*, and the thyrsoïd Bellflower usually attracts the notice of those who come across it in a garden because of its colour. It deserves some notice in other respects, as its general appearance is otherwise very unlike that of the other *Campanulas* with which we are more familiar. It has entire pilose leaves, forming a kind of rosette, from the centre of which rises the dense pyramidal spike of bloom. The upper part of the spike forms a dense inflorescence of small sulphur-coloured sessile flowers which are sweet-scented and open from the top downwards. Taking it altogether, it is

The Thyrsoïd Bellflower (*Campanula thyrsoïdes*).

one of the most distinct of the genus. Notwithstanding this, it has one grave fault. This is, that it is only a biennial. It usually grows from a foot to a foot and a half high, and prefers a light, rather dry soil in a sunny position. Thus it is more suitable for the rock garden than the border, although a group in a good border is always attractive in its season of bloom, which is generally about July. Its treatment is comparatively simple. The seeds should be sown preferably under glass in April or May, covering them lightly with fine soil and placing the pots or pans in a cold frame or one with a little bottom-heat, moving the seedlings when strong enough to where they are to bloom. It is a native of the European Alps and was introduced in 1785.

Mr. Chas. Oakford, The Gardens, Mells

Park, Frome, who kindly sent us the photograph from which the illustration has been prepared, writes as follows:—

Campanula thyrsoïdes is a good thing among *Campanulas*, and I do not think it is often met with. It has done well with me in the rock garden. The flowers are rather dull in colour, but they are very sweet scented.

NOTES AND REPLIES.

Heuchera sanguinea not flowering.—Will you kindly inform me if *Heuchera sanguinea* requires special treatment to make it flower? I have a strong, healthy-looking plant of it, which has doubled in size in three summers without producing a single flower. It is on a rock bank, well-drained, sunny, and open, ordinary garden soil. Will any special fertiliser help? Ought it to be moved every couple of years, as I have seen suggested, or is it unlikely to succeed near a town?—Z. M.

[In not a few instances this is a shy bloomer, though this is rather due to position than any special soil. It is said to be partial to frequent division and replanting, but we doubt it, more especially if the plants are growing in a very dry, overdrained soil. In certain positions we would only divide and replant every third year. This plant is much more a cool and shade-loving subject than many think, and if a deep soil in a shady corner can be given it all will be well. It is not a suitable plant for a cold clay soil, and prefers that of a leafy nature to which has been added plenty of sandy loam. With this, endeavour to combine a little shade, and see that the soil does not become too dry.]

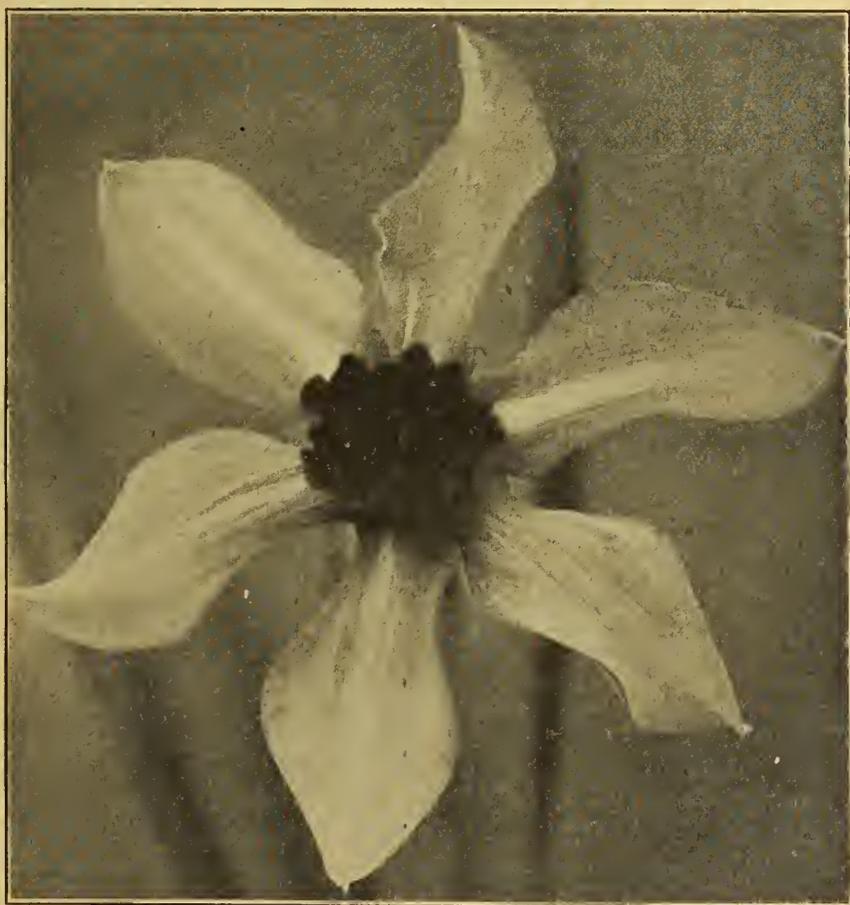

Antirrhinums in the flower garden.—Like "W. McG.," I have been struck with the freedom with which *Antirrhinums* have been planted in the station gardens of the Glasgow and South-Western Railway. I quite agree with him regarding the desirability of employing more decided colours in some cases. As he remarks, the pinks and yellows ought to be more decided. I have specially observed the want of brightness in some of the yellows, especially in those grouped with whites. Some of the whites are inclined to be cream rather than pure white, and a poor yellow beside these detracts from the brightness of the beds. It is a little disappointing, also, to see how the yellow *Calceolaria* is so much planted, when there are so many other more pleasing plants. "W. McG." is also correct in his remarks about the scarlet *Zonals*. In some seasons they are excellent for station gardens, but latterly in the gardens referred to they have suffered so much from wet as to be disappointing in the extreme. *Begonias* generally do better in the south-west of Scotland, but railway station gardens are so much exposed to draughts that they are frequently dried up in summer and autumn, and then the *Begonias* suffer. At some of the first prize stations the best effects were produced by the herbaceous perennials supplemented by annuals. A great annoyance to some of those in charge of these gardens is caused by rabbits, which are very destructive in some quarters.—S.W. SCOTLAND.

Hardy-flower borders.—These still remain very bright, and the later forms of *Asters* are beginning to be noticeable. These include the viminalis type, as well as the *Novae-Angliae* and *Novi-Belgii* varieties, which go far towards maintaining a display during the rapidly-shortening days. A most useful variety is *A. Drummondii*, one of the very latest, if not quite the latest, flowering *Asters* with which I am acquainted. So late is it, indeed, that unless protected by scrim it is occasionally cut down by the earliest frosts before blooming. Nevertheless, it is worth inclusion in any collection, even with this drawback, for it is distinct alike in colour, habit, and foliage

from other Asters. Outstanding have been the Phloxes. The cool, dripping season has evidently met their requirements perfectly. Not only has growth been more robust than usual, but the trusses are larger, and individual pips clear and distinct, but the time of duration has been more prolonged than usual. Phloxes, of course, are hungry subjects, requiring plenty of nourishment; and it will be found that young pieces are always the most satisfactory. As has been said, all have done well, but *Eclairneur*, *Coquelicot*, and *Crepuscle*, with perhaps *Chateaubriand* in addition, have been the pick of the collection.—W. McG., *Kirkcudbright*.

NARCISSUS INCOMPARABILIS TORCH.

MANY of the newer high-priced Narcissus are unattainable by the greater number of flower lovers, and it is always well to grow some of the finest of the varieties obtainable at a moderate price. Such a

Narcissus Torch.

one is Torch, here illustrated. It is a very handsome, vigorous, and early variety, the perianth yellow, the segments long and twisted, with a crown of glowing orange-scarlet. F. W. G.

Erigeron mucronatus.—I am always grateful for this little plant in the autumn, as it goes on blooming till the frost, producing its delicate little pink and white, Daisy-like flowers in the utmost profusion. Its only fault is that its seeds travel all over the place, the seedlings springing up everywhere. However, they are easily pulled up where they are not wanted, and the plant is so graceful and unassuming that the seedlings are often allowed to remain. It likes a gritty, well-drained soil, but otherwise needs no special care.—N. L.

Thymus micans.—Although the flowers of this Thyme are inconspicuous, it makes such a neat little bush of grey-green or golden foliage that it is pleasing all the year round. I think it is by far the sweetest smelling of all the Thymes.—J. W. O.

INDOOR PLANTS.

SOFT-WOODED WINTER-FLOWERING PLANTS.

THE time is at hand when all soft-wooded plants that have been grown for winter flowering, including Pelargoniums, Begonias, Salvias, Marguerites, Eupatoriums, *Lassandra macrantha*, and *Libonia penrhosiensis* should be under cover, or, at any rate, sheltered from incessant rain and cold. If not in pits or frames an extemporised covering should be provided, as the cold is apt to arrest growth and too much rain washes out all the good properties of the soil. One does not often see *Libonia penrhosiensis*, but it is one of the best of the smaller winter-flowering plants, decidedly superior to *L. floribunda*, being of better habit, brighter and clearer in the flower, and

thum, although of very little use for cutting or as a room plant, is valuable for the size and brilliant colour of its flowers. *Hardwick.* E. B. S.

NOTES AND REPLIES.

Calceolaria Clibrani unhealthy.—Can you tell me what is the cause of these leaves turning colour in this way and if there is any cure for it? I have grown this *Calceolaria* (*C. Clibrani*) for some years in a greenhouse and it has always done very well, but this year both the old plants and the cuttings are nearly all affected in this way.—K. M. B.

[We have not met with a parallel case to yours, and, after careful examination, we have come to the conclusion that the trouble is of fungoid origin. There is no trace of insects on the leaves sent. A course of treatment likely to prove successful would be to spray the foliage both on the undersides of the leaves as well as the surface with a rose-red solution of permanganate of potash. It readily dissolves in water and is cleanly to use.]

Mignonette in pots.—In the greenhouse the shortage of bulbs will be felt, more especially in the spring. *Mignonette*, therefore, will be very useful, and during the week a sowing was made for the purpose under notice. Usually the seeds have been sown in 5-inch pots, the seedlings thinned down, and the resulting plants bloomed in 7-inch pots. An experiment is being made during the present season by sowing the seeds in 10-inch pans, which are fairly deep. It is intended to leave three plants in each pan when thinning is completed. The compost used consists of old loam, which has been stacked for some years, and which is now so friable that it can be rubbed down to the necessary fineness with the hands. A very little leaf-mould is added, together with some fine mortar rubbish and a sufficiency of sharp sea-sand. In filling the pans, the soil is made quite firm, and the seeds are only lightly covered. The pans are placed in a cool greenhouse until germination is visible, being kept covered with obscured glass. When the seedlings are sufficiently large for the first thinning the pans will be removed to a cold-frame until they are required.

CHRYSANTHEMUMS.

CHRYSANTHEMUMS IN SMALL POTS.

(REPLY TO "WOULD-BE GROWER.")

CHRYSANTHEMUM blooms, each from 4 inches to 5 inches in diameter, borne upon plants not more than 1 foot high and requiring pots only 4 inches wide at the most, are desirable subjects to have where the filling of small vases with living plants and flowers is a necessity during the winter months. Such plants can easily be obtained if a few simple details of culture are carried out. Early in August is the time to commence the cultivation of these miniature plants. Both Japanese incurved and Anemone Japanese varieties are suitable for this form of growth. The preference should be given to those varieties which are strong in growth, avoiding those that have slender peduncles, as they need so much support to show off their blooms to advantage. One advantage of cultivating plants in the manner named is that any points of growth which may through accident be broken off the plants which are intended for the supply of large blooms can be utilised. From now onwards some points are sure to be broken off the plants. The ligatures which support the plants will have become too tight to allow of the shoot growing. The growth is thus "buckled," so to speak, and then snaps off about 4 inches long generally, or heavy rains will sometimes damage the succulent growths, or birds will alight on the extreme points where they extend beyond the top of the stake, or are not kept tied to the supports. If more shoots were allowed to each plant when growth first

much more enduring. It makes a good companion to *Primula obconica* and *P. malacoides*.

It is generally recommended to put all the above plants into pits or frames through the summer months, and very good places they are if not too much exposed to the sun. Where such is the case it is advisable to shade a little during the hottest part of the day, otherwise the plants dry out very quickly, necessitating far more use of the water-pot than is advisable. It is as well to loosen the surface of the soil and give a small dose of some fertiliser before putting the plants into winter quarters. Any of the plants subject to insect pests should be overhauled and remedial measures taken. Salvias, for instance, are rather subject to red spider in hot, dry summers, the *Lassandra* to thrips, and the Marguerite to the leaf-boring maggot. The *Lassandra*, or as it is now generally called, *Pleroma macran-*

was made from the natural break in May than it is intended shall develop blooms, such surplus shoots will furnish capital material for the subject in hand.

From the first to the last week in August is the best time to strike the cuttings. If the cuttings are inserted sooner than the date named, the plants after being struck are liable to get too tall, and if taken later than the last date the flowers are liable to be much smaller. Varieties with large-sized blooms may be rather taller than smaller-flowered sorts, as the drooping florets show to greater advantage on a correspondingly taller plant. The cuttings should be firmly dibbled into pots 2½ inches in diameter, and well watered to settle the soil. Plunge the pots in a gentle hot-bed, shading the cuttings carefully from the sun. Syringe the foliage every afternoon on fine days, and by keeping the frame nearly close, roots will be formed in about a month, when air should be admitted gradually and afterwards freely when the plants will bear exposure without flagging. When the plants are well supplied with roots they should be shifted into pots 4 inches in diameter, using a fairly rich compost and potting the plants very firmly. When the roots have taken to the new soil the plants should have abundance of air, so that the growth may be stocky and the foliage clean. No place suits them better than a shelf close to the glass in a cool house. As soon as the pots are filled with roots, stimulants should be given to the plants freely, as they require plenty of support when growing in such small pots.

THE WEEK'S WORK.

OPEN-AIR GARDENING.

IN BLOOM OCTOBER 11TH.—*Amaryllis Belladonna*, *Montbretias*, *Gladioli*, *Colchicum speciosum album*, *Hardy Cyclamens*, *Sternbergia lutea*, *Oxalis*, *Linarias*, *Androsaces*, *Lobelia cardinalis* (in variety), *Verbena venosa*, *Pentstemons* (in variety), *Salvias*, *Enotheras* (in variety), *Achilleas*, *Platystemon californicus*, *Omphalodes cappadocica*, *Corydalis thalictrifolia*, *C. lutea*, *Convolvulus mauritanicus*, *Hutchinsia alpina*, *Dwarf Campanulas*, *Mazus Pumilio*, *Plumbago Larpentæ*, *Sedum spectabile*, *S. Sieboldi*, *Valerian*, *Acanthus*, *Helenium*, *Helianthus* (in variety), *Michaelmas Daisies* (in great variety), *Scabiosas*, *Statice*, *Linum arboreum*, *Tufted Pansies* (in variety), *Gazania splendens*, *Nigella*, *East Lothian Stocks*, *Acrocliniums*, *Potentillas*, *Leptosiphons*, *Nemesias*, *Begonias*, *Cosmos*, *Pelargoniums* (in variety), *Marguerites*, *Calceolaria amplexicaulis*, *Ageratum*, *Antirrhinums* (in variety), *Argemone*, *Agathæa cælestis*, *Heeria elegans*, *Dwarf Erigerons*, *Mesembryanthemums*, *Myosotis*, *Sweet Violets*, *Rudbeckias*, *Pyrethrum uliginosum*, *Francoas*, *Dahlias*, *Cannas*, *Tritomas* (in variety), *Early-flowering Chrysanthemums*, *Erigerons*, *Clematis* (in variety), *Tropæolum speciosum*, *Dwarf and Climbing Roses* (in variety), *Cyperus longus*, *Polygonums* (in variety), *Pampas Grasses*, *Nymphæas*, *Hypericums* (in variety), *Genista tinctoria*, *Lavatera Olbia*, *Laurustinus*, *Escallonia montevidensis*, *Hydrangea paniculata grandiflora*, *Hardy Fuchsias* (in variety), *Viburnum coriaceum*, *Abelia rupestris*, *Spiræa Thunbergii* (second flowering), *Myrtles*, *Vernonias* (in great variety), *Daphne Dauphini*, *Calycanthus occidentalis*, *Magnolia grandiflora*, *Desmodium penduliflorum*, *Clerodendron trichotomum*, *Jasminum nudiflorum*, *Buddleia variabilis magnifica*, *Berberis nepalensis*, *Ericas* (in variety), *Menziesias*.

WORK OF THE WEEK.—The planting of Wall-flowers, *Myosotis*, *Polyanthus*, *Aubrietias*, *Alyssum*, and other spring flowers has been continued and will shortly be completed. It is important that the ground be in a proper condition for planting, to allow the plants to be set firmly, as a protection against wind and frost. A few of each sort are kept in reserve for filling blank spaces where the

plants have died. *Salvia patens* has been lifted, the tubers placed closely together in boxes filled with sifted soil, which is made quite firm. The boxes are then placed in a frost-proof shed and kept quite dry. In this manner they winter well. To increase the stock of *Ourisia coccinea*, a few clumps have been lifted from the rockery, the soil washed away, the rhizomes carefully detached with roots, and potted up three together in 4-inch pots in well-prepared sandy soil. The pots are stood in a cold-frame, which is kept close until the plants have made fresh roots, after which plenty of air is admitted. These will be planted out in their permanent positions in March.

Where it is intended to plant *Roses* this autumn, preparations should be made without delay. As these plants occupy the ground for several years, it is necessary that the soil receive a thorough preparation at the start. *Roses* may be planted during favourable weather at any time from now until March, or even April if the work is done with care; but, undoubtedly, the best time of all is the latter part of October and November. At this time the ground is still warm, and the plants have an opportunity to become established before the winter. Therefore, the work of trenching should be hastened, so that the ground may settle somewhat before the time for planting. The best soil for *Roses* is a strong, rich loam of a heavy nature, having natural drainage. Light, sandy, or gravelly soils are unsuitable, but may be improved by taking out a quantity of the staple and adding good, rich, heavy loam. When trenching, dig in plenty of decayed farmyard manure at the bottom of the trench, but do not allow the manure to come into contact with the roots. F. W. GALLOP.

Lilford Hall Gardens, Oundle, Northants.

SOUTHERN COUNTIES.

Tomatoes.—After this date it can hardly be expected that the fruit will ripen properly outdoors. All fruits of nearly full size should be cut and taken indoors and placed on a stage or on shelves, where, if situated so that they experience full light, they will quickly colour and become fit for use. The smaller or not fully-grown fruits can then be used for the making of chutney and other purposes. On plants under glass still carrying a nice lot of fruit the greater part will ripen given a period of bright weather. As an aid towards attaining this end, give less water at the roots and maintain a dry, airy temperature. The plants grown for winter, on which the trusses of flowers are now expanding, should, to facilitate the setting, be kept rather on the dry side and be fertilised daily or the trellis smartly tapped about mid-day to ensure a good set. A sweet, dry, and airy temperature, maintained either with or without fire-heat, according to circumstances, is also necessary, the reverse conditions being conducive to failure.

Late Peach-house.—Every effort should now be made to get both foliage and wood properly ripened, using a slight amount of fire-heat if at command if it appears necessary to attain that end, and freely ventilating the house also.

Maincrop Leeks.—These should now be finally moulded up, first drawing the tops together and tying them temporarily together with raffia to facilitate the placing of the soil around them. They do not need to be earthed up to too great a height, as the object should be to obtain plants having stems large in circumference rather than of less dimensions and of greater length. This condition will result if plenty of well-rotted manure was placed within the reach of the roots and feeding has been properly attended to.

Spring Cabbage.—The plants from the second sowing are now ready for getting out into their permanent quarters. As these will form a succession to those planted earlier in the season, it is not so essential that they be accorded quite so warm and sheltered a position, otherwise they will be turning in too close on the heels of the former, and cause a glut. Rather more space should also be afforded the plants, allowing them a distance

of 18 inches each way. Plant in drills drawn about 4 inches deep, which can be filled in later when the plants have made sufficient growth, both to steady and protect the stems.

Bedding plants.—*Pelargoniums* of all types will now be the better for being placed under cover, *Vineries* from which the fruit has been cut being very good places for the purpose when heated pits are not available or non-existent. Carefully pick off all dead leaves before housing them, and allow them all the space that circumstances permit to prevent their becoming drawn. *Lobelia*, *Iresines*, *Heliotropes*, *Cupheas*, *Ageratums*, etc., require rather warmer quarters, otherwise the losses from damp will most likely be great.

Violets.—Pits and frames should now be got ready for the planting of both single and double varieties. The beds should be made up of a sufficient depth that the plants when set out will be close up to the glass, this being more essential in the case of the double than the single kinds. The double kinds should be planted without delay, but as the singles are still flowering freely, planting in their case may be deferred for another week or ten days. In both cases use good, sound, fresh loam in which to plant them, adding just enough leaf-mould and old Mushroom manure to render it suited to their requirements. Give the plants a good soaking of water as soon as planted, and if lifted with a good ball the sashes need not for the present be placed over them.

Tuberous Begonias.—Pot plants should now be placed under cover, if only in frames, to facilitate the ripening of the stems. When this has been accomplished the pots may be stored away close together in a dry frost-proof place. If space is limited they can be knocked out, relieved of the crocks, and stood as close as possible together in boxes, which, if of convenient depth, may be stood one on the other.

Fuchsias.—These, like the preceding, should now be stored, first relieving them of decaying leaves before placing them under cover for the winter. Any place where frost will be unable to reach them will, so long as it is dry, suffice for these.

Cyclamens.—These having made a full complement of leaves, and beginning to push up their flowers, a house must now be got ready for them. This must be light and sufficiently heated to ensure a temperature of 60 degs. to 65 degs. without the over-heating of the pipes. Before taking the plants in, the structure must be scrupulously cleansed and the walls white-washed, etc. A. W.

MIDLAND COUNTIES.

Root-pruning is a necessary operation in the case of trees making rampant growth, in order to bring them into a fruitful condition, especially if such trees have been established for many years and it is considered unsafe to transplant them. For younger trees transplanting is decidedly better, the removal at once checking the exuberant growth which young trees frequently make for a few years. The present is the most suitable time for this work to be undertaken. In root-pruning, before taking out the necessary trench make sure that the soil is in a moist condition, and if it is not give a good watering and wait for a few days. Take out a trench 4 feet from the base of the trunk, and afterwards gradually work away the soil towards the stem with a fork quite down to the drainage, carefully preserving all fibrous roots and tracing to their original thong-like fibreless roots, which cause the excessive wood growth. Search well under the ball of soil, as these roots—known as tap-roots—often penetrate straight down into the subsoil. Cut well back all such roots, making an upward, sloping cut, so that the new roots that will be formed may be encouraged to grow towards the surface. Return the soil to the trench, making it quite firm about the roots, and lay out evenly all roots with the points trending upwards. It is advisable to put a few inches of fresh soil on the surface to keep the roots there. Should the weather remain dry for long afterwards, it may be necessary to afford water to the trees thus treated. Extra large trees should only have half their roots interfered with this autumn, the remainder being dealt with next year.

Raspberries.—Those who have unprofitable Raspberry canes should now make preparations for planting afresh. October is the best month for making a new plantation. Raspberries will succeed in almost any soil provided the water can pass through it easily and that it is at the same time one that never becomes very dry. If the soil is light in texture and rich in plant food, then deep cultivation is all that is necessary, except for a liberal dressing of well-decomposed manure. On cold and wet ground some additional preparation will be necessary, as the soil must be drained and trenched, adding such materials as burnt refuse, decomposed manure, leaf-soil, and road-scrappings. Any or all of these materials may be used to make the soil more porous, and they will improve the ground for a number of years to come. The Raspberry being rather a shallow-rooting plant, the richest compost should be kept near the surface. The planting of the canes may be carried out according to the aspect of the ground. It is generally best to have the rows extending from north to south, and these rows should be from 4 feet to 5 feet apart, putting each plant at a distance of from 2 feet to 3 feet apart in the rows. After planting is completed apply a light mulch of stable-manure or some other light material over the roots.

Freesias.—The earliest batch of Freesias is now growing freely in a position close to the glass in a south aspect. A little weak liquid-manure is afforded the roots twice each week. As the earliest batch of

Roman Hyacinths is showing signs of top growth this has been removed from the plunging-bed and placed in an unheated frame. In about a week a batch will be placed in the forcing-house, and plenty of tepid water applied to the roots, and as soon as the foliage and flower-spikes begin to develop they will be placed as close to the glass as possible.

Cyclamens.—The earliest plants are showing their flower-buds, and have been given a good position in a light, well-ventilated house. Seedlings raised during the autumn are now ready for pricking off. The largest will be potted singly into thumb-pots, using a light compost of equal parts of sifted loam, leaf-soil, and plenty of silver sand. Press the soil firmly and place the young plants near the glass in an atmospheric temperature of 60 degs., shading them from direct sunshine.

Indoor plants.—All kinds of indoor plants, especially those of a soft-wooded nature, need to be watered with extra care at this season. Syringing must also be reduced, and if overhead syringing is necessary in the warmer houses to keep down insects it should only be done once a day, and in the morning after the temperature has risen a little. As the weather becomes colder it is advisable to drop the temperatures of the houses a little rather than use an excess of fire-heat.

Celery has done remarkably well this season, especially the plants of the later batches. Continue to place earth about the stems on fine days, especially in the case of the very latest batches. It may not be necessary to blanch all the crop for the present, as when the shoots are blanched the plant is more tender and likely to be injured by frost.

Late Peas.—Owing to the favourable weather, late Peas have been plentiful and the quality good. There is every appearance that in the absence of frost the supply will continue for another month. Early varieties of

Rhubarb which are grown for forcing will be lifted as soon as the foliage has died down, leaving the roots intact as far as possible, and allowing them to rest for a period on the surface of the ground under a north wall, covering them with a little long litter to prevent the wind drying them unduly. This will give the roots a check, which is necessary, as Rhubarb is not easily forced at this season. The warmer end of the Mushroom-house is set apart for Rhubarb. After removal to the Mushroom-house, the roots are covered with ordinary soil, and the crowns and surroundings damped twice daily with tepid water.

Tomatoes in the open.—Many fruits are now on the point of ripening, the plants generally being in full bearing, owing to the backward season. To obtain the best results under the

circumstances the plants have been cut off at their base with the fruits attached and suspended their full length in the vineries. By this means they retain their plumpness much better than if cut off individually or in clusters, and the supply will be kept up for some considerable time. A sowing of Tomato seed will now be made to raise plants for spring cropping under glass. Sow in pans, cover the seeds lightly with fine soil, and stand the seed-pans on a gentle hobbed until the seedlings are well through the soil, when they should be raised to within a few inches of the roof-glass. When the plants are large enough to handle they are potted singly into small clean pots filled with a compost of two-thirds loam, one-third sifted leaf-mould, and sufficient coarse sand to render it porous. Grow them close to the roof glass, and when they begin to make fresh growth admit air in sufficient quantity to prevent them becoming drawn. Avoid exposing the plants to cold draughts or they may become stunted. F. W. GALLOP.

SCOTLAND.

Late Potatoes.—At a slightly earlier date than usual a beginning was made in the course of the week with the lifting and storing of late Potatoes. The crop cannot be described as being more than moderate. It was anticipated that, owing to the wet season, disease might prove to be more than usually prevalent; but such is not the case. In most areas of considerable size disease is generally present in a greater or less degree, and during the lifting (so far as it has gone) no more diseased, or partially diseased, tubers than might be expected in the ordinary course of events have been found. The tubers are, however, rather disappointing in respect of size, and there is a marked absence of the extra large specimens which we have been accustomed to expect. Especially is this noticeable in the case of my favourite, King Edward VII., which, for some reason, has been a comparative failure. This, however, does not interfere with the high opinion which I have formed concerning this excellent Potato, and I shall have no hesitation in planting it equally freely next season. Up-to-Date and British Queen have, on the whole, been fairly satisfactory. Storing is done at the close of each day's lifting when the weather is fine, and the tubers are kept in a cool, well-ventilated, and frost-proof house. Lifting will be persevered with, as opportunity offers, until the whole of the late Potatoes have been stored.

Onions.—These, which had been laid out in a sunny position to dry off, have now been removed to their winter quarters. In storing, a strict look out was kept for slightly damaged specimens, these being put on one side for immediate use. Many growers like to "rope" their Onions; but I find that they are more easily dealt with and keep quite as well when they are laid out thinly in a house with a temperature similar to that in which Potatoes are kept, but with rather more light, semi-darkness being apt to induce premature growth in the case of Onions.

Apples.—Further progress was made with the gathering and storing of Apples—a comparatively easy task during the present season. At this time of the year we in this district are at times compelled to gather certain Apples at an earlier date than is absolutely necessary for two reasons. The one is, birds are very numerous, and blackbirds, especially, attack the fruit and soon work considerable damage. The other reason is that the autumn gales, from which we suffer every season, bring down the finer samples; so that, on the whole, it is more profitable to anticipate the gathering by a week or two in the case of mid-season Apples in the open. The case is different with trees on walls, such as Ribston Pippin, Margil, Nonpareil, Court Pendu Plat, and others of that type. These require to hang as long as possible. It is easy to circumvent the fruit-eating birds by close netting. It is regretted that our local Apple, the Gallopway Pippin, a good and long-keeping variety, has failed entirely.

Pears.—In the case of Pears, the wall trees are now inspected frequently, and such fruits as part from the tree when lifted to a horizontal position are gathered. On the whole, the crop, though late, is fairly satisfactory.

During the week the picking of William's Bon Chrétien was completed. Some good samples of Louise Bonne de Jersey were also secured, and if not quite ripe when picked the fruit soon matures when stored in a comfortable temperature for a short time. The crop of this fine Pear is highly satisfactory, both on old and on young trees. A fine crop of Pitmaston Duchess has been gathered. The fruits, although of a good size, are not so fine as usual, still they are quite large enough. There has been much discussion about this Pear. Certainly it is not in the foremost flight, but when grown on a wall and thoroughly ripe, it is not to be despised. A look over was given to later Pears—Doyenné du Comice, Glou Morceau, Winter Nelis, Marie Louise, and so forth—to see that tits, sometimes troublesome, had not begun to peck the fruits at the stem. All these are bearing useful crops, as is Souvenir de Congrès, which, though it does not ripen so soon as it ought to do, owing to its position, is nevertheless a very useful Pear.

Plums.—The season of Plums is now practically over, only trees of Coe's Golden Drop, Reine Claude de Bavay, and Pond's Seedling remaining to be dealt with. The crop has been, for these gardens, a light one, although such varieties as those just mentioned, Washington, and Kirke's did very well. The crops of Jefferson and most of the Gages were very indifferent.

Peaches.—The latest variety grown out-of-doors, Dymond, is now being picked. Although later than usual, and in spite of an unfavourable season for out-of-doors Peaches, the fruits of this variety are well coloured and of quite average size. Peach-trees in the open are at times, and especially if September be a sunny month, predisposed to attacks of red-spider. No traces of this pest have during the season been visible, and this is directly attributable to the cool weather. Nectarines Humboldt and Stanwick Elruge yet remain unripe, and it is now feared that the fruits may have to be ripened artificially. This is a somewhat critical operation—the fruits, if picked prematurely, shrivelling instead of ripening.

Hardy flower borders.—The hardy flower borders begin to assume a rather untidy appearance. It is much better to tolerate this than to try, by cutting over ripening stems and so forth, to smarten up these borders. Such things, however, as spent colonies of annuals and similar subjects which have ceased to be effective may be dispensed with, and, where time can be spared for the purpose, a little tying up and a stir with the hoe will go far to make things passable for the brief time which now remains to the hardy flowers.

Salvia Pride of Zurich.—In the course of the week a quantity of this showy Salvia was lifted and potted up from the beds in which it was grown. These plants are mainly intended to provide cuttings in spring for next year's work. In an ordinary year beds of this plant are very showy, but owing to the unfavourable summer they have not this year been a success.

Arum Lilies.—The last of the Arum Lilies were potted up towards the end of the week. These had been planted out during summer, and have started into vigorous and healthy growth. In potting, a rather retentive soil was used, with but a moderate allowance of sand and a sprinkling of soot. Pots 10 inches in diameter were used, each pot accommodating four crowns. Space was left for top-dressing at a later date. Meantime, these plants have been placed in an unbeated structure, from which, in order to make room for them, exhausted Tomatoes were removed.

Fruit-houses.—Fallen leaves ought to be regularly removed from all fruit-houses, and alike in Peach-houses, orchard-houses, and vineries, in which the foliage is now ripening, the syringe or garden engine should be kept at work. If this be neglected there is a chance of red-spider putting in an appearance. Borders must be inspected from time to time, for while they may not require much moisture, it should be remembered that any dryness at the roots will inevitably result in bud-dropping. If there are no plants in fruit-houses (a practice always to be deprecated) let the ventilation be ample both by day and night.

W. McGuffog.

Balmoe Gardens, Kirkcudbright.

ROYAL HORTICULTURAL SOCIETY.

OCTOBER 10TH, 1916.

DESPITE the frequent meetings held recently that on the 10th inst. was of considerable extent and variety. Two collections of excellent fruit were staged, one from a private garden, the other from a trade source. Roses from Twyford and Oxford were as fine as could be desired, which, nearing mid-October, is saying much for the varieties concerned and their profuse flowering. Collections of beautiful and rare shrubs from more than one source aroused a new interest in these at a seasonable time for planting, while affording a good idea of their value. Dahlias, too, were very fine, their quality demonstrating the mildness of the time and the freedom from autumn gales. In hardy plants the chief novelties were Michaelmas Daisies, and there is proof that important work is being done among them. Ferns, Orchids, Sweet Violets, and Carnations were well shown. Several important novelties received awards.

HARDY PLANTS.

Chief among the novelties in this section was the welcome Genm Borisi, a plant of hybrid origin suggestive of the influence of *G. Heldreichii superbum* or *G. miniatum*, or both. Orange-coloured externally and showing a deep scarlet surface not unmixed with orange, it is particularly brilliant, and, being free-flowered, effective also. The single flowers, too, are large and very shapely. It was presented by Mr. Clarence Elliott and gained an Award of Merit. From the same source, too, came a pair of *Gentiana sino-ornata*, that brilliant alpine which, as *G. ornata* variety, gained an Award of Merit a fortnight ago. The former is the authenticated name. From Messrs. Baker Limited, came a new pure white double Michaelmas Daisy, *J. S. Baker*, that may be likened to a pure white Beauty of Colwall. As shown, it was very pure and good, and likely to be of much value to both gardener and florist. It gained an Award of Merit. This firm also showed a considerable variety of Michaelmas Daisies, *Blue Gem* (the finest blue we know), *Edith Goodwin* (blue), and *Peggy Ballard* being notable among many. Quite a brilliant lot of flowers of the common *Gentianella* (*G. acaulis*) was staged by Mr. G. Kerwell. These late flowers render it highly acceptable now. A new *Colchicum* provisionally named *C. illyricum superbum* presented by Messrs. Barr and Sons and gaining an Award of Merit also attracted considerable attention. Of sturdy habit, with roundly-formed flowers of rosy-lilac, it was most effective. Some new and highly promising Michaelmas Daisies were sent by the Hon. Vicary Gibbs, Elstree, Herts (gardener, Mr. E. Beckett). The plants were growing in tubs, and well displayed habit and merit. Of the set, *King of the Belgians*, with large, shapely, mauve-coloured flower-heads, gained an award. We thought highly, too, of *Brightest and Best*, a *Novi Belgii* form with trusses of bright rosy-red flowers. Its warm colour alone will make it popular in the garden, where, if massed, it would prove most effective. Other good novelties from this source included *Namur* (rosy-pink), *Mons* (reddish-purple), *Brussels* (soft lavender-blue), and *Aerschot* (deep blue inclining to semi-double). *Cimicifuga simplex* was shown by two or three firms, Messrs. W. and A. Clark, Limited, and Mr. W. Wells, Juur. To the former lot the addition "*Clark's variety*" was added to the specific name. We detected no difference beyond the purity of the flowers, due, unmistakably, to the examples having been pot-grown and

flowered under glass. Mr. Wells also had *Echinacea* (*Rudbeckia*) *purpurea* in good condition; also the new *Asters*, *Brightest and Best* and *King of the Belgians*, which, we understand, have passed into his hands. The more notable things from Mr. G. Rente were *Satyrion roseum* and *S. carneum*, only rarely seen. *Phillyrea viburnoides* is a shrub novelty from China having terminal cymes of creamy flowers. *Polygonum amplexicaule* was brilliant, *Cimicifuga simplex* very pure, and *Campanula muralis* still full of bloom. A table group of Michaelmas Daisies from Messrs. Waterer, Sons, and Crisp showed these to advantage. The finest thing, however, was the intensely-coloured Italian *Stewart*, *Ultramarine*. We know nothing like it. *Lustre* (red), *Cloudy Blue*, *splendens* (rich blue), *White Diana*, and *Nancy Ballard* (rosy), of the first-named set, were also good. The *Violets* from Mr. J. J. Kettle have never been better shown, and they were greatly admired. They were chiefly double-flowered. *Mrs. J. J. Kettle* (silvery-mauve), *La Belle Parisienne* (an improved *Marie Louise*), *Comte de Brazza*, and *Marie Louise*, all in ample bunches, were among those making quite a feast of these popular flowers. A group of Michaelmas Daisies from Messrs. W. Cntbush and Sons included the rosy-red *Sirius* and the indispensable *Climax* (blue) among many others.

ROSES.

The wealth and beauty of these were remarkable, and rarely have finer blooms been staged at this season. We were particularly struck with those from Mr. Elisha J. Hicks, who had a wondrous display of the new single crimson *Princess Mary* among many sorts. We thought it finer than ever, and Mr. Hicks has been showing it since March last at frequent intervals. No single Rose is so brilliant, few more delightfully fragrant or so little inclined to mildew. Two great banks of it were separated by a big group of the semi-double cream and yellow *Joanna Bridge*. *Charles E. Shea*, a glorious pink, is the H.T. novelty of the moment. It gained a Gold medal, we believe, last year. *Ophelia* and *Mme. E. Herriott*, the latter rich in colour and still full of buds, were others. Mr. G. Prince, too, had some lovely Roses, none so chaste, graceful of form, or set in such a profusion of buds as the pure white *Mrs. H. Stevens*, which a big stand showed to perfection. *Moonlight* (white cluster), *Josephine Nicholson* (pink), *Rayon d'Or*, *Edith Malcolm* (flesh), *Mrs. Alfred Tate*, *Mrs. David McKee* (cream), *Lady Hillingdon*, and *Mme. E. Herriott* were also abundantly represented. *Rev. J. H. Pemberton*, in addition to *Moonlight*, *Queen Alexandra*, *Clytemnestra*, and others, showed good vases of *Comtesse du Cayla* and *Rayon d'Or*.

SHRUBS.

Messrs. Piper staged a most comprehensive collection, which also embraced some few choice and rare. Of these, *Olearia semi-dentata* (white stems and woolly leaves), *Elsholzia Stauntoni* (pink flowers in Veronica-like spikes), *Osmanthus armatus* (the lustrous, leathery leaves margined by curved spines), *O. rotundifolius* (neat and distinct), *Caryopteris mastacanthus* (a good blue-flowered shrub), *Buddleia macrostachya Yunnanensis* (spicate racemes of white flowers and woolly leaves), *Rubus Veitchi* (silvery), and *Viburnum Henryi* (one of the most distinct of its race) were remarked among many things. Messrs. George Paul and Son had a striking hybrid novelty in *Laurns Cerasus cheshuntensis* (*azorica* x *lusitanica*), a handsome plant likely to displace the *Bay* for tub work and terrace

gardening. The graceful, silvery-stemmed *Salix pruinosa*, *Prunus Pissardi nigra* (of good leaf colour) and *Yucca Ellacombei* were other notable things. In a group from Messrs. John Waterer, Sons, and Crisp, the foot-high *Cotoneaster pyreuaica* was a feature. Rarely exceeding that height and of neat trailing habit, subsequently it should prove ideal to the rock gardener. *Pittosporum eugenioides variegatum*, *Leptospermum bullatum* (white flowered), and the scarlet trumpet *Honey-suckle* (*Lonicera sempervirens*) were also remarked. *Acer cratægifolium*—the name appears to be a misnomer—is the most brilliant-leaved *Acer* we have seen. Its effect in the garden in sunlight would be gorgeous. Messrs. J. Cheal and Sons contributed *Ceanothus* in variety, *Pernettyas*, cut shrubs, and a collection of clipped bushes, Mr. L. R. Russell showing a considerable collection of tree *Ivies* grown in pots and tubs.

MISCELLANEOUS.

Dahlias were contributed by Mr. J. B. Riding, in whose set *Marianne* (a dwarf bedding sort of self orange colour) claimed attention at once, and by Messrs. J. Cheal and Sons, who had many good singles and a delightful series of "*Star*" varieties, *Scarlet Star*, *White Star*, and *Crawley Star* (the original) being well shown. The most conspicuous *Dahlia* novelty was the *Paeony-flowered J. A. Jarratt*, which bears the raiser's name. The revolte florets are heavily tipped, fiery scarlet. *Rex Begonias*, all too rarely seen to-day, were in some variety from Messrs. H. B. May and Sons, and interspersed with many good Ferns. Fascination was the richest-coloured, *Lady Veitch* and *Silver Queen* others of note. Carnations were well presented by Messrs. Allwood Brothers, particularly *Nora West* (a lovely pink), *Nancy* (the latest salmon-pink novelty from America), and *Destiny* (cerise), also from across the water. Some three dozen amply-filled vases were on view.

ORCHIDS.

The pure white *Cattleya Saturn* from Messrs. Armstrong and Brown was among the most chaste varieties shown, their *Cattleya Venus*, *Orchidhurst* variety, one of the most remarkable. Its ruby-crimson lip and golden-bronze petals were in striking contrast. It originated from *C. Dowiana* x *C. Iris*, and, framed after the latter, is three times its size. Messrs. Charlesworth showed the beautiful tri-generic hybrid *Sophro-Laelio-Cattleya Lutetia*, with reddish sepals and petals, its ruby-red lip having a touch of bronze-gold at base. *Brasso-Cattleya Veitchi Queen Alexandra* (an almost pure white form) was included in the group. A particularly good form and well-flowered plant of *Vanda cœrulea* came from Mr. C. F. Waters. The choicest thing, from Messrs. Sander and Sons, was the pure white *Cattleya Lady Veitch*, variety *superbissima*. *Cattleya Cowana alba* from Messrs. J. and A. MacBean was chaste and beautiful, the new *Odontoglossum percultum*, variety *Nicator*, from Mr. E. G. Mocatta, Woburn Place, very fine. It and the two first-named novelties gained Awards of Merit.

FRUIT AND VEGETABLES.

A table of fruit in variety, excellent for the most part, came from Mr. C. A. Cain, Welwyn, Herts (gardener, Mr. T. Pateman). Pears and Apples were in much variety, the former being particularly good. The dishes of Peaches *Sea Eagle*, *Lord Palmerston*, and *Plums Golden Drop* and *President* were of exceptional quality. Good bunches of the leading Grapes were in the background. A *Hogg Silver Medal*

was awarded. Basket-dishes of Apples of much excellence and considerable variety were contributed by the Barnham Nurseries, Limited. Egremont Russet, Allington Pippin, Brownlee's Russet, Ben's Red, and Lane's Prince Albert were among the finer varieties shown.

A complete list of the certificated plants and medals for groups will appear in next issue.

CORRESPONDENCE.

PLANTS AND FLOWERS.

Kalosanthes coccinea (W. S.).—This is one of those good old greenhouse plants that have from some cause or other ceased to be popular. Not many years ago it was one of the most brilliant plants in collections of stove and greenhouse plants, for its natural season of flowering when grown in a greenhouse is from midsummer to the end of July, a time there is not so much variety in plants that bloom naturally as there is in May and early June. If half-a-dozen strong shoots are placed round the edge of a 4-inch pot they will soon strike root, and in the spring, if shifted into 6-inch pots, will produce many heads of bloom. The plants do not need very large pots, and quite large specimens may be grown in pots of from 8 inches to 10 inches in diameter. By cutting out the old straggling growths after flowering the plants may be kept of useful size for a good many years.

Watering pot plants (M. T.).—It is not possible to lay down any hard-and-fast rule, as so much depends upon the temperature of the house, the nature of the soil, and the state of the weather. For example, soft-wooded plants like Fuchsias and Heliotropes, cannot go very long in a warm house without needing moisture. On the other hand, it is possible to over-water delicate Ferns like some of the Adiantums, though liking an atmosphere charged with moisture. It is scarcely possible to give Spireas, especially when near the blooming period, too much water. Azaleas and other peat-loving plants often suffer from want of water, although they may appear damp on the surface, and this is because, peat being of such a close, retentive nature, enough water is not given to penetrate to the ball of roots. After all, as in other departments of gardening, it is the daily attention which brings about the most satisfactory results. When sending several queries, kindly read our rules as to putting each one on a separate slip of paper.

FRUIT.

Peach-tree leaves, insects on (A. M. M.).—In all our experience we have but seldom seen the leaves of Peach-trees in such a bad state. They are infested with brown-scale, red-spider, and thrips, showing all too plainly that the trees have been allowed to get dry at the roots, while moisture in the house, so inimical to the two latter pests, has been neglected. The best thing you can do is to thoroughly water the border in which the trees are and wash the foliage with the garden engine. When the leaves fall gather them all up and burn them, and wash the whole of the shoots with an insecticide, also thoroughly cleaning every part of the woodwork and limewashing the wall with a mixture of hot lime to which some sulphur has been added. No half measures will do any good. The failure of the Vine is, no doubt, due to the rats, while it may be that the leaves of this have fallen a prey to red-spider and thrips, due, also, in great measure, to the soil of the border being dry and want of moisture in the house.

VEGETABLES.

Tomatoes diseased (Mrs. Lawrence).—Your Tomatoes have been attacked by the same disease as affects Potatoes, due to the cold wet weather we have lately had. The cultivation of Tomatoes in the open air is very risky, as in but few seasons can a satisfactory crop be had. All the diseased fruits should be at once gathered and burned. We should also advise you to gather all the remaining fruits, even if only partly coloured, and lay them on

a shelf in the greenhouse where they will ripen sufficiently to come in useful for cooking.

Scarlet Runners not setting (A. R.).—The cause of your Beans not setting is not from want of fertilisation, but food or moisture at the roots. As they are in full leaf water does not get to the roots, which get dried up; the flowers then drop because they need more moisture. A thorough watering, also liquid-manure if you have it, afterwards will often save the crop.

MISCELLANEOUS.

Destroying woodlice (Cucumber).—Woodlice in a Cucumber-frame can best be destroyed by setting traps for them. Flower-pots filled with dry hay and then inverted, and placed in the corners of the frame, will attract great numbers of them. Examine these pots every morning, and shake out the insects into a bucket of boiling water, and also pour boiling water round the edges of the frame, being careful in doing so not to wet the foliage or shoots of the Cucumber plant with it. If this is persevered with they will soon disappear.

Weeds in lawn (Croquet Lawn).—Judging from your letter, no half-measures will be of any avail. Your best plan will be to have the lawn trenched, clearing out the weeds as this is being done, adding plenty of good rotten manure. Do this as early as you can, so that the soil can settle down. If you can get good, clean turf in the district, then you may return it after having made it quite level and firm. If not, then you had better wait until April, when you can sow it down. The above is a drastic remedy, but it is the only thing you can do in the case of a lawn that is so over-run with bad weeds as yours seems to be.

SHORT REPLIES.

M. A.—It is very difficult without seeing your trees to give any advice as to pruning. By far the best plan would be for you to consult a practical gardener in your neighbourhood, who on seeing the trees could suggest what had best be done with them.—*L. I. O.*—See reply to your query in our issue of September 16, page 464.

NAMES OF PLANTS AND FRUITS.

Names of plants.—*T. L.*—1, Cupressus Lawsoni erecta viridis; 2, Thuja elegantissima aurea.—*T. M. S.*—Cape Figwort (Phygelius capensis).—*H. T. Shawcross.*—Bugbane (Cimicifuga simplex).—*Mrs. Phipps.*—Your specimen was named in our issue of October 7th, page 510. We do not reply to queries by post. See our "Rules to Correspondents."

Names of fruits.—*T. L.*—Apples: 1, Lord Derby; 2, Newton Wonder.—*Amelius.*—A, Kentish Fillbasket; B, Probably Yorkshire Greening; C, Cox's Pomona. Please, before sending fruit for name, kindly read our "Rules to Correspondents." As Apples vary so, it is very difficult to name with any certainty when only one specimen is sent.—*A. O.*—Apples: 1, Cox's Pomona; 2, Ribston Pippin; 3, Wellington; 4, Blenheim Orange.—*A. H.*—Apples: 1, Cellini; 2, Lemon Pippin; 3, Norfolk Beaufin; 4, King of the Pippins.—*J. Simpson.*—Apples: 1, Lord Suffield; 2, Lord Derby; 3, King of the Pippins. Pear: 4, Mme. Treyve.—*J. Ross.*—Pears: 1, Williams' Bon Chrétien; 2, Beurré Bose. Apples: 1, James Grieve; 2, Cox's Orange Pippin.—*W. S.*—1, Plum Coe's Golden Drop; 2, Pond's Seedling.—*Pomum.*—Apples: 1, Manx Codlin; 2, Blenheim Orange; 3, Yorkshire Beauty; 4, Wellington.—*W. O. S.*—Apples: 1, Grenadier; 2, Bramley's Seedling; 3, Alfriston (very late); 4, French Crab.

A GARDEN ON A FELL.

You may be a dreamer of dreams all your life, but seldom does it fall to the lot of man that his dreams take form and substance.

In GARDENING ILLUSTRATED, November 8th, 1913, in an article called "Nature in the Garden," I indulged in a day dream of a garden on a moorland planted with Heaths. It was to some extent a criticism of one of a series of garden essays of *The Times*. The particular dogmas I attacked were these:—

"Large or small, the garden should look both orderly and rich. It should be well fenced from the outside world. It should by no means imitate either the wilfulness or the wildness of Nature, but should look like a thing never to be seen except near a house. It should, in fact, look like part of the house. There are, of course, very skilful specialists who, by the expenditure of a great deal of pains, can make a wild garden beautiful, but those who hope to imitate natural beauty with less trouble than it would take to make a pleasant formal garden will surely be disappointed."

Thus *The Times*.

I asserted that the style of a garden should be governed by the kind of country in which the house is built, and amongst other instances gave that of an imaginary house in a moorland country where the great variety of Heaths now in cultivation could be used with brilliant effect:—

"There would be in the short, grassy soil of the moorland garden a sea of Erica carnea intersected by rivers of the cushioned French Gorse, with billows of the hybrid Mediterranean Heaths behind, and in the further distance bold groups of E. australis, more beautiful than the Lilac and more durable in effect, and the fine, upstanding Portuguese Heath, with feathery plumes in early spring. Surrounding the back of the house and sides the Commemara Heaths, and beyond them again the Cornish Heaths. There would be never a season of the year without some great vista of bloom. To many of us this escape from the tyranny of beds and pergolas would be as welcome as the open sky to a dweller in a factory town."

Mr. Hoyle, who calls his house appropriately enough "Above Beck," has to a very large extent realised my dream. Here, on the steep side of a fell overlook-

ing Grasmere, he has planted with very great skill a perfect moorland garden. Down the fell runs a little mountain stream which falls over the face of a splendid rock, picturesque and natural as anything could be. On each side of the little stream, or Beck, as they call it in those parts, the fell side is planted richly with nearly all the best known Heaths in masses. The access to this fell-side garden is made easy by paths partly stepped running crosswise. Half-way up this delightful garden a beautiful terrace intersects the fell. This is formed with the natural rock of the country and is 160 yards long by about 15 yards wide. It is carpeted with the velvety turf which the rainfall of this lovely country keeps ever green. There are two well-built stone summer-houses at each end, and the view from this terrace over Grasmere, the lake, and the mountains is enchanting. The garden contains many beautiful alpine plants, flourishing in their natural habitat.

Let us see how far this garden conforms to the dogmas put forth in *The Times*.

It is well fenced, but there is no appearance of this from below, for the garden looks like what it is, part of the fell. I do not know if it can be said to imitate Nature. It is Nature, and in its wilfulness and wildness lies its charm. The house is a good stone building worthy of its situation, and you feel that it has the garden it ought to have, a garden that appeals to the eye of an artist, a living picture in a picturesque country.

SYDNEY SPALDING.

NOTES OF THE WEEK.

Some Californian plants at home.—In the issue for August 26th (p. 421) I noticed an account by "North London" of *Zauschneria californica*. In California we have two forms—*Z. c. microphylla* and *Z. e. latifolia*. *Z. c. microphylla* is a shrubby variety and the one probably referred to, and the other a broad-leaved, dwarf, creeping form found in the mountains at 5,000 feet to 6,000 feet elevation, and so would be much hardier than *Z. c. microphylla*. It is very free-flowering and is four to six weeks earlier, a point of interest to English growers. In another note "Kirk" speaks of *Diplacus glutinosus*. We have at least five distinct forms here—two red ones, two yellow, and one intermediate variety ranging in colour from red through to yellow. One yellow form is found in company with *Zauschneria e. latifolia*, growing beneath

boulders at 5,000 feet to 6,000 feet. It is also a dwarf 6 inches to 12 inches in height, the flowers being of a light buff-yellow, early, and free. Coming from the ice and snow it also should prove perfectly hardy for rock or wall gardens.—J. HARRY JOHNSON, *Plantsman, Los Angeles Park Dept.*

Cynoglossum amabile.—This is a good addition to annual flowers—bold, free grower, good blue, and is good in effect as I write (October 8th) after flowering through the summer. It is best in a bed of yellow Tea Roses rather openly planted.—W.

Caultheria tricophylla.—I counted today (October 1st) between sixty and seventy ripe berries on *Caultheria tricophylla*, most of them so entirely hidden by the foliage that a casual observer would never see them. On two other plantations which have hitherto been far the most prolific I only found one berry.—E. CHARLES BUXTON, *Coed-Derw, Bettws-y-Coed.*

Chrysanthemum Soeur Melanie.—The pure white blooms of this are borne with the greatest freedom. In the south, no doubt, the variety would expand its blooms in the open, but further north, unless protected by tiffany, frost is apt to occur before the display is general. The plants, if lifted in October and given the shelter of a greenhouse, will provide a wealth of material for cutting over a long period.—KIRK.

Gentiana verna.—This plant, with me, flowers twice in a season, in spring and in autumn. I wonder why this plant does so, seeing in some places it fails to flower at all? On the other hand, I cannot, or at least have not yet, managed to flower *G. acaulis*. It has been tried in varying positions, but the plants dwindle away. *Gentiana verna* is grown in full sun in a front position on the rockery.—C. T., *Hightate.*

Note from Bucks.—A man who prunes Holly and Yew would do anything. It is a curious thing how hard pruning seems to die, and one sometimes wonders if it ever will. The Jalap plant (*Ipomæa Purga*) is beginning to bloom, and there is a good show of Nerines. *Lapageria* also had about a dozen good blooms on it. Do you succeed well with *Romneya Coulteri*? My plants have a habit of doing very well the first year, and then slowly getting worse and worse each year. I think they like all the sun one can give them.—M. Y.

[Sun and free soil should do, and good, young plants are essential; plant in April, using seedling plants.—Ed.]

Rose George Dickson.—This is one of the finest velvety-crimson Roses we have, the colour of the blooms in the autumn days being very rich, while to this is added the fact that it is very sweet-scented. Those who are looking for a richly-coloured, sweet-scented Rose that flowers freely in the autumn should find room for this.

The Blue Bindweed.—I have this in various positions on walls and as edgings, usually working with plants from cuttings. This year a batch, raised from seed in spring, is now flowering very well as a carpet beneath Tea Roses. A more beautiful plant for the flower garden has not been introduced. It is still in good bloom—early in October.—W.

Erodium corsicum.—My plants of this are still (beginning of October) covered with their bright pink flowers and seem to be inexhaustible. They only ripen a few seeds with me, which no doubt helps to prolong the flowering period. To my mind it is quite one of the prettiest of the family. I grow it in a rather poor, very gritty soil.—J. W. O.

Crocus speciosus albus Bowles's White.—This is one of the many new Crocuses we owe to Mr. E. A. Bowles, and a great beauty it is. The flowers are large, of good substance, and of wonderful purity. On first opening, the outside is slightly flushed with pale blue at the base, but this soon disappears. The inside is pure white with the exception of faint purple lines towards the base. This is the best white form of *C. speciosus* which I know.—S. ARNOTT.

Crinum Powelli.—I am glad to see, page 514, that "E. H. Jenkins" recommends *Crinum Powelli*. Some bulbs in my rock garden, planted ten years ago, have again flowered well this autumn. Nothing has been done to them since they were put in, and they have needed no protection in the winter. Do you recommend dividing the bulbs in order to increase them?—M. C. GILLET, *The Elms, Banbury*.

[So long as the bulbs are doing well we should leave them alone, but if you wish to increase your stock, then the best way is to lift them and remove the offsets.—Ed.]

I have a specimen of this fine *Crinum* now carrying seven spikes. The first spike has really finished blooming, and the last one has not opened its flowers, but given a continuance of mild, fine weather, no doubt it will expand. It has never before thrown up more than three spikes in a season, so seven must bespeak unbounded vigour and soundness. The *Crinum* being a deep-rooting plant, many of this plant's roots must now be down in the clay, for the place prepared for it did not exceed 2 feet in depth when planted about seven years ago. The plant gets no protection in winter unless it comes unusually severe, when I place a mound of sand or ashes around the stem. This shows that *C. Powelli* is hardier on cold soils when established than is generally supposed.—C. TURNER, *Highgate, London, N.*

Pyrus (Sorbus) Vilmorini.—This was one of the shrub novelties that gained an Award of Merit at the Royal Horticultural Hall on September 26th last. A Chinese plant as yet not well known in this country and bearing certain affinity to the Mountain Ash section of the race, it appears so far as is at present known to incline to a bush-like habit of growth rather than the small tree character of the Mountain Ash. It is an attractive shrub, the long pinnate leaves and branching clusters of fruits, rose to scarlet in colour and quite *Pernettya*-like in these respects, being somewhat out of the common. Grouped

on the lawn so that other plants—e.g., Lilies—might be associated therewith, it would make quite a new feature. Bearing seeds freely it should soon be available in plenty.—E. H. J.

The Western Yellow Pine on the Sierras.—In support of what I wrote recently as to the need of respecting the natural habit of trees of the Pine tribe I quote this from Jepson's *Sylva of California*.—W.

The Yellow Pine is the most abundant and widely distributed tree of the forests of California, and is particularly characteristic of the Sierra Nevada, where it attains its finest development. The largest trees most commonly grow along the ridges, and it is the ridges which the trails ordinarily follow. Here the traveller may journey day after day over needle-carpeted or Grassy ground mostly free of underbrush, amidst great, clean shafts 40 feet to 150 feet high, of really massive proportions, but giving a sense of lightness by reason of their colour, symmetry, and great height. No two trunks in detail of bark are modelled exactly alike, for each has its own particular finish, so it is that the eye never wearies of the fascination of the Yellow Pine, but travels contentedly from trunk to trunk and wanders satisfyingly up and down their splendid columns—the finest of any Pine.

Cotoneaster Dielsiana.—Seeds of this species were originally sent home by Mr. E. H. Wilson in 1900, and it created a good impression a few years later when exhibited in full fruit at one of the autumn fortnightly meetings of the Royal Horticultural Society. It was at that time exhibited under the name of *C. applanata*, but it had apparently been previously named *C. Dielsiana*, which is now the accepted name. One of the deciduous-leaved set, it forms a light-branched shrub 6 feet to 8 feet high, with long, slender branches clothed with dark green, ovate leaves, from the axils of which, on short shoots, the small, rather inconspicuous flowers appear in June to be followed later by bright red or almost scarlet fruits, which ripen in September and remain on the bush for a couple of months or more if protected from birds. It is a native of Central China, and one of the most attractive of the several species that have been recently introduced. It thrives in good, loamy soil, and can be increased either by seeds sown in spring or by cuttings of half-ripe shoots inserted in light soil in a close frame during summer.—D.

Sweet Verbena (Aloysia citriodora) in Scotland.—Some weeks ago there was an interesting article on fragrant plants in your columns. Among others mentioned was Sweet Verbena, and it was remarked that it flourished in the milder parts of Scotland. This I can vouch for. In Campbeltown, Argyle, there is an old bush growing in a warm, sheltered corner of a garden. It is never protected in any way. I took the opportunity of measuring it, roughly, the other day, and found it was fully 9 feet high and about 8½ feet through—truly a noble bush, and its fragrance is truly delightful. A younger bush has been planted as a companion, and it also has grown to nearly the same size.—SCOTUS.

—In our mild climate the Sweet-scented Verbena (*Aloysia citriodora*) will remain out of doors for a succession of seasons, but, in the event of a very severe winter, such pieces will succumb. One such plant which has been outside during the past few years has assumed the proportions of a shrub, some of the present year's shoots being almost 9 feet in height, while the plant is nearly as much through.

On the other hand, pieces raised in heat from cuttings in spring, hardened off, and put out in late June are only a little over 3 feet high, in some cases slightly under that height. Of course, the unfavourable season must be taken into consideration, but it is clear that, where *Aloysia citriodora* will stand the winter out of doors, better results may be obtained than by annually raising young plants from cuttings, even if the former are cut down to the ground-line.—W. McG., *Balmac*.

FRUIT.

GRAPE CHASSELAS NAPOLEON.

I SEE that Chasselas Napoleon has been exhibited recently at the Royal Horticultural Society's Fruit Show. The fact that it was in the winning collection of six varieties where the competition was keen proves that this is a fine Grape when well grown. It was in 1867 that I made the acquaintance of Chasselas Napoleon, when exhibited in company with about 400 varieties of Grapes in the Paris Exhibition. These Grapes came from the south of France and varied greatly in colour. Some were white, some were tinted with amber, and there were all shades of chocolate, purple, and black. The difference between many of them was, naturally, minute. They were probably mostly local varieties, which had at various times originated in the vineyards, many, perhaps, being chance seedlings. Among them Chasselas Napoleon was prominent and distinct, and I thought at the time that in the hands of English Grape growers it would be a fine addition to the varieties grown under glass in this country. The bunches exhibited were from the open air. The berries were of medium size, but finely coloured, and it seemed to me that this variety would be a good companion for the Hamburg and Buckland's Sweet-water. The colour of the berries and the flavour seem to indicate that it is a cross between Muscat of Alexandria and the Chasselas, so much grown in France. It would be interesting to know what treatment is given to this Grape at Clumber. Is it grown with the earlier-ripening kinds or with those that require a considerable amount of artificial warmth? For years past I have been watching for some account of this Grape, but have not in the course of forty years come across a Grape grower who had ever cultivated it, and not more than one who knew of its existence. Anyway, it is evident that it is worth the attention of Grape growers in this country.

J. CORNHILL.

NOTES AND REPLIES.

Apple Allington Pippin not fruiting.—I will be obliged if you will tell me if the shoots with bud at tip I send you should have been pruned away on Apple Allington Pippin? The tree was first started on wires as a cordon, but from neglect in pruning became a bush. It has never fruited though four years planted, and the gardener prunes off the branches every year to the third eye. Is this right, or should these branches with the bud have been left?—A. L.

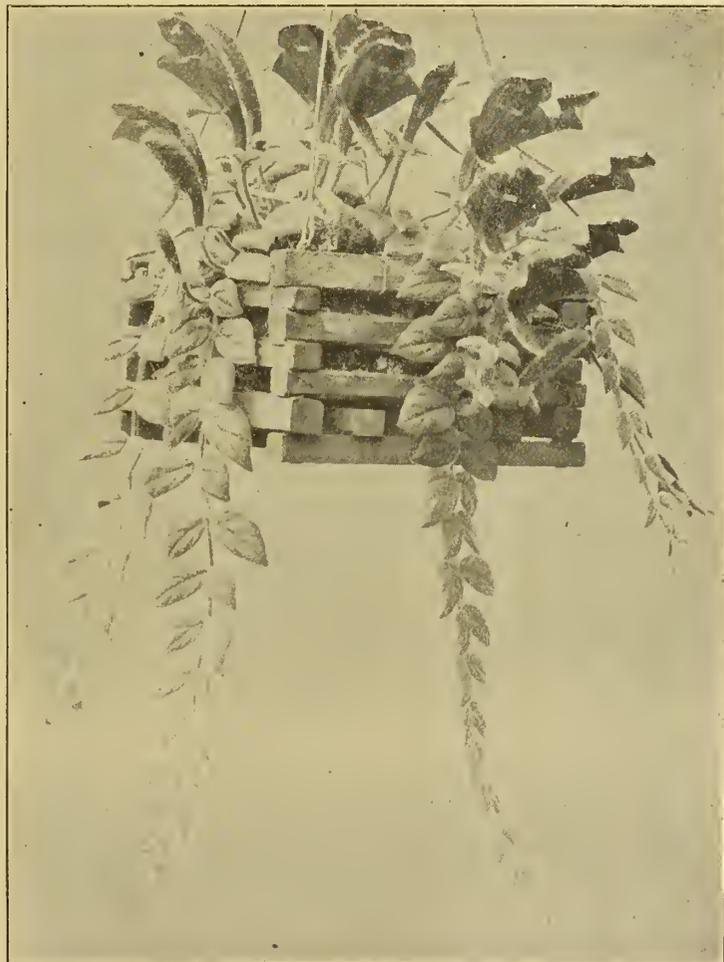

[The variety of Apple mentioned is prone to form fruit-buds at the points of the young shoots. These may, when it can be done without unduly shading the buds on the spurs behind them, or when it is not likely to lead to a congestion of young shoots, be left to fruit and then be cut away. As a rule, Allington Pippin produces such an abundance of fruit-buds on the spurs as to render those formed on the tips of the shoots superfluous, and we invariably sacrifice them when winter pruning. We are, however, always careful to leave five buds when cutting these shoots back in

summer and retain four at the winter pruning. Too close pruning leads to the production of growth alone, and this may be the reason why your tree has not yet fruited. If, after treating the tree as we advise, next season it still fails to fruit, lift it and replant it.]

"Sleepiness" in Pears.—Never a season passes in which there are not complaints of sleepiness in Pears. This is not a disease as is by some supposed. It is merely an indication that the fruits have not been used soon enough, and that the first symptoms of decay are setting in. Some varieties are more prone than others to this fault, Williams' Bon Chrétien being a confirmed offender in this respect. Generally speaking, it will be found that early and mid-season Pears are more apt to go sleepy than later sorts, but even the

a somewhat pronounced flavour and aroma, as Cornish Gilliflower, Ribston, Margil, and others, are the favourites of the birds, and one occasionally comes across varieties in out-of-the-way cottage gardens practically unknown to commerce that seem very susceptible to attack. I have one, apparently a good type of Pearmain, on which they started early, but a plentiful supply of strips of old curtains hung in different parts of the tree checked the onslaughts, although, I fancy, the ripening of the fruit in wood, covert, and hedgerow may have drawn them in other directions.—E. B. S., *Hardwick*.

Pears.—Many varieties are ready for storing, and the following have been gathered: Beurré d'Amanlis, Beurré Superfin, Beurré Hardy, Fondante d'Automne, Pitmaston Duchess, Louise Bonne of Jersey, Marie Louise, Hessele,

Columnea gloriosa at Glasnevin.

latter will go "sleepy" if they are kept too long. A good deal depends on the fruit-room. A cool, uniform temperature ought to be aimed at, fire-heat being only permissible to bring on a variety which may be required at an earlier date than that at which it will naturally mature. Pears ought to be allowed to hang as long as possible upon the trees, too early picking, I think, being one of the chief factors in the production of sleepiness.—KIRK.

Late Apples.—It being advisable to let the late Apples hang as long as possible before gathering, it will be found necessary to keep a sharp eye on those varieties for which birds have a decided partiality, and, where it is not possible to net the trees, to try some means of keeping them at bay; also to have some plaster of Paris ready to hand with which to stop any tiny holes as soon as the fruit is gathered. Yellow-fleshed Apples with

Seckle, and Thompson's. Many of the later varieties should be allowed to hang on the trees until nearly the end of October, shrivelling taking place if gathered too soon, these later sorts requiring a longer time to mature. The varieties mentioned above must be examined every few days, as they ripen quickly when stored, and will not keep in good condition for a long time.—F. W. G.

Apple Warner's King.—This is an overpraised Apple. Many growers who planted this in small gardens or as restricted trees soon found out their mistake. In my garden the owner planted eight trees some ten years ago. When I came these were in positions where they had to be pruned, but those I could allow to extend have borne heavy crops for four years or five years, while those restricted have not paid for the room they occupy. I have seen this Apple give enormous crops on large standard trees on the free loam of Ilminster in Somerset. With me it is a poor keeper, but commands a good price in the market owing to its size.—WEST SURREY.

PLANTS AND FLOWERS.

INDOOR PLANTS.

THE COLUMNNEAS.

THE Columnneas, which consist of a large number of species, belong to the Gesneria family. In a state of nature most of them occur as epiphytes in the forests of Central America and in the warmer parts of the southern portion of that continent. Their cultural requirements are much the same as those of the different *Æschynanthuses*, also belonging to the order Gesneraceae. The genus *Æschynanthus* is, however, as a rule, confined to the tropics of the old world. Most of the Columnneas will succeed when grown in hanging-baskets, as in the accompanying illustration of *Columnea gloriosa*. A suitable compost may be made up of fibrous peat, Sphagnum Moss, and sand. During the growing season they need liberal supplies of water, while at no time must they be allowed to get dry. They may also be grown in pots into which an upright piece of dead Tree Fern stem has been placed. The shoots will in time clothe the stem, and a very pretty effect is produced when the plant is in flower. A prominent characteristic of some of the Columnneas is the large size of the curiously hooded blossoms. The flowers are scarlet and yellow. A notable feature is the pretty, bronzy tints of the hairy leaves. Much in the same way is *hirta*, with deep green leaves; indeed, by some *gloriosa* is regarded as but a variety of this. *Columnea glabra* is an upright shrubby species, with small, fleshy, glossy green leaves and long, red flowers, while *C. magnifica*, also an erect grower, has hairy leaves and brilliant scarlet flowers. Within recent years a first-class certificate was given to *C. Cerstediana*, a species whose long pendent shoots bear a profusion of erect scarlet flowers. A curious, yet attractive, species is *C. Scheideana*, whose large flowers are coloured brown and yellow. Between *C. glabra* and *C. magnifica*, M. Lemoine, of Nancy, has raised a very desirable hybrid, whose large upright flowers are of a rich scarlet colour. It is more or less erect in habit. There are many other species, but few, if any, of them are in general cultivation.

K. R. W.

BOUVARDIAS.

WHERE a greenhouse has to be kept as gay as possible throughout the year the different Bouvardias are of great service. While the long-tubed, white-flowered, fragrant *B. Humboldtii corymbiflora* will flower during the summer, the others are at their best during the last three months of the year. If cuttings are struck early in the year neat little bushes may be obtained in 5-inch pots by the time the flowering season comes round. By some, Bouvardias are planted out during the summer and lifted and potted before the flowering season, but this is, I think, not so much practised as at one time. They can all be propagated by means of root cuttings, but I prefer to take the young growing shoots which have been brought forward in a gentle heat, treating them the same as *Fuchsia* cuttings. They will form neat flowering plants the first season, but if larger specimens are desired they may be grown on a second year. When it is intended to treat them in this way they, as soon as the flowers are over, should be kept somewhat drier at the roots in order to give them a partial rest. Then early in the year they should be pruned into shape and placed in a structure a little warmer than an ordinary greenhouse. As soon as the young shoots

make their appearance the plants should be repotted in a mixture of loam, leaf-mould, and sand. In potting, as much of the old soil should be removed as can be done without unduly distressing the plants. For this potting they may not require pots any larger than those in which they have flowered, but may be shifted into larger ones when growth is more active.

VARIETIES.—A selection of the best varieties would include *alba odorata jasmiflora* (blush-white), *elegans* (scarlet), *Humboldtii corymbiflora* (white), *King of Scarlets* (large scarlet flower, white tube), *Mrs. Robert Green* (salmon-pink), *President Cleveland* (vivid scarlet), *Priory Beauty* (delicate rose), and *Vreelandi* (pure white). The above are all single-flowered varieties, a few of the best doubles being *Alfred Neuner* (white), *Bridesmaid* (pink), *Hogarth flore pleno* (scarlet), and *President Garfield* (pink). This limited number has been raised in different parts of the globe, for *King of Scarlets* comes from Australia, *Alfred Neuner*, *President Cleveland*, and *President Garfield* from the United States, *Hogarth flore pleno* from the Continent, while most of the others have been obtained in this country. W. T.

NOTES ON GREENHOUSE PLANTS.

BOUARDIAS.—The excellence of these, as seen in some of the London market gardens, would surprise those familiar with the class of plant commonly seen in private gardens. It cannot, of course, be expected that amateurs with a miscellaneous collection of plants which all vary somewhat in their needs can compete with the market grower, who concentrates his energies on three or four things, the peculiarities and needs of which he has studied for years. As regards the *Bouvardia*, the mistake commonly made is in coddling the plants too much. Early in spring they need to be brought along in a rather confined atmosphere, with plenty of overhead sprinklings, but as the season advances they should get plenty of air, and by the end of June they are best in the open, and well supplied with moisture. They must never get dry. When the weather is warm they make a short, stout growth, which is able to produce large heads of high-quality blooms. Grown all through the summer with other things under glass the plants are apt to become somewhat attenuated and the flower trusses poor in quality. Those who may have been rather disappointed with this fine greenhouse plant should try the above method, which is practised by the experts who produce those fine specimens which form a feature in Covent Garden Market during the winter and early spring.

KALOSANTHES COCCINEA.—There was a time when this was very popular with amateurs. At the present time I fancy that it is not much grown. Properly managed, it is a very attractive greenhouse plant, the deep green foliage displaying the vivid tints of the flowers to great advantage. It is, moreover, easy to cultivate and is a good thing for the amateur who has not expert knowledge of plant culture and has not, perhaps, much time to spare for gardening. Some things, if they get on the dry side in the growing time, are much checked in their development, but the *Kalosanthes* shows a happy indifference to neglect in this way so long, of course, as it is not pushed to an extreme. The great fault that amateurs committed in those days was in retaining old plants instead of putting in a cutting or two every year. The plants in the course of a couple of years became gaunt, bare of leaves at

the base, and therefore unsightly. Such plants can be cut back and dwarfed, and the very big specimens, some 4 feet across, which once formed a feature in collections of stove and greenhouse plants at the big shows were treated in this way, but this involves shifting along into larger pots, and in a general way the amateur does not want to go beyond the 6-inch pot stage. Where there is ample glass accommodation and there is a large conservatory to decorate, well-grown, large specimens are useful, as they afford a welcome variety to *Zonals*, *Tuberous Begonias*, etc. For small growers the best way is to put three cuttings into a 3-inch pot in August and shift into a 6-inch pot the following spring. This will give dwarf specimens with foliage down to the pot.

ROCHEA FALCATA.—It is a long time since I have seen this old inhabitant of our gardens mentioned. It belongs to that class of plant which was cherished by a bygone generation of plant growers. Like the *Kalosanthes*, it comes from the Cape, and, therefore, loves sunshine and air, but, unlike it, frequent propagation is neither necessary nor desirable. Plants may remain in the same pots for several years, and retain and even increase their blooming power if well supplied with water and a little stimulant in the growing time. This old Cape plant is quite distinct from any other greenhouse plant, and the big heads of orange-scarlet blooms are very striking.

HABROTHAMNUS FASCICULARIS is showy and of very easy culture. It should be grown on into 8-inch pots and the compost should be generous, loam with a little well-decayed manure suiting it best. The great thing is to induce a free, strong growth and mature the same by exposure to atmospheric conditions from July to September. With this treatment full-sized heads of bloom will be obtained. J. CORNHILL.

NOTES AND REPLIES.

Phyllocactus fruiting.—Is it rare for a *Phyllocactus* to bear fruit? I have one the size of a hen's egg, dark reddish-purple.—OLD WOMAN.

[It is by no means unusual for *Phyllocacti* to bear fruit; indeed, most garden varieties have been raised from seeds.]

Adiantum with long stems (p. 424).—The best form of *Adiantum cuneatum* for producing long stems is *A. c. elegans*, and the best method of ensuring them is to raise young plants periodically from spores and grow them in brisk heat and moisture. Growing them under Vines, whether in small or large pots, is starvation to them; the heat is not brisk enough, the moisture insufficient. The length of the fronds given not only proves this, but shows also that the plants are more or less exhausted. Young plants less than a year old raised from spores, if grown on briskly in a temperature of about 80 degs. would produce fronds of three times the length stated. Market growers, who are constantly picking the fronds of these as they are ready, know that there is a limit to endurance, and, realising this, raise fresh stock periodically to replace that exhausted. The low, well-heated houses are fairly heavily shaded, and in the growing season reek with moisture. Of course, there are long-stemmed varieties of *Adiantum*, but, lacking the grace of the above-named, are not in demand. I once saw the *British Maiden-hair* with fronds 18 inches in length in rather exceptional circumstances. The greenhouse stage rested on brick arches, and the plant, becoming established at the back with the growth constantly drawing to the light,

fronds several times the length of those ordinarily produced had resulted. The exceptional circumstances of their production were interesting rather than otherwise and of little practical use to the gardener.—E. H. JENKINS.

Pelargonium Unique.—There is certainly a revival in favour of the various scented-leaved *Pelargoniums*, in some of which the blossoms are remarkably showy. Among them the variety *Unique*, represented by different forms, occupies a prominent position. The least showy of them is what is usually referred to as the old *Unique*, whose flowers are of a deep lilac tint. Surpassed by none of the others is *Rollisson's Unique*, with rich violet-crimson blossoms. *Mrs. Kingsbury* (magenta-crimson) is also in the same way, while in *Scarlet Unique* the flowers are scarlet, but of a somewhat dull tint. It has a decided blotch of maroon. All of these are what may be referred to as of a straggling habit of growth, but there are several ways in which they can be utilised in the greenhouse. They may be treated as wall or pillar plants, under which conditions blossoms will be freely produced throughout the summer and well on into the autumn. At this season they are, from their bright colours, particularly attractive. Good examples may also be grown if the flexible branches are trained round a few sticks, and, as they will flower freely in this way, they afford a pleasing change from the Zonal varieties. In bygone days they were at times grown as specimen plants. In this way, if carefully attended to, they soon covered a good-sized trellis. Like all the rest of their class, *Pelargoniums* root readily from cuttings, and their cultivation is simple, provided they are kept clear of aphides. Other scented-leaved kinds whose blossoms are also particularly showy are *ardens*, said to be a cross between *P. fulgidum* and *P. lobatum*. The flowers of this are bright scarlet, blotched inside with a deeper tint. Also worthy of mention are *Clorinda* (deep rose), *Lady Mary Fox*, also known as *Scarlet Pet* (soft red, maroon blotch), and *M. Nonin* (bright scarlet).—W. T.

Aphelexis humilis.—Though the *Aphelexis* are now included in *Helichrysum*, the older name still holds good in gardens. At one time a considerable number of species was catalogued, but now most of them are regarded as varieties of *Aphelexis humilis*. It, or at all events one of its forms, was much grown as specimen plants when these were so generally cultivated and largely exhibited. *A. humilis* forms a bushy specimen from 18 inches to 2 feet in height, the branches covered with white tomentum. The flowers, which open only during sunshine, are of a clear satiny-pink, and if gathered before they are too far gone and dried will retain their colour and shape for a very long time. The type and its varieties need much the same treatment as *Cape Heaths*—viz., a compost consisting mainly of peat and sand pressed down firmly, a well-ventilated structure, and careful watering.—W. T.

Freesias have started into growth and the material used for covering has been removed. They are exposed to all the light and air possible to ensure a sturdy growth, and when the cooler weather sets in the plants will be removed to a shelf in a light, well-ventilated house. Watering must be done with great care, for *Freesias* are very impatient of too much moisture, rarely succeeding well if this happens. As support becomes necessary, provide neat stakes. The plants require to be kept growing steadily, but at no time must they be subjected to excessive heat. An atmospheric temperature of 50 degs. to 55 degs. is quite sufficient during the winter.

ROCK, ALPINE, BOG, FERN, AND WATER GARDENS.

SAXIFRAGA OPPOSITIFOLIA SPECIOSA.

THE experiences which have recently been exchanged between growers of alpine plants as to the likes and dislikes of this particular section of the genus, variable as they undoubtedly are, should go a long way to tempt those who have not tried them to grow some of the more beautiful of a very desirable race. The measure of success attained under varying conditions in diverse localities goes to show that the plant is not fastidious in the majority of instances, hence one to garden with on a generous scale. Sheeting the earth with countless blossoms in white, crimson, and purple in a way comparable to no other, and giving of this wealth when not many hardy plants are astir—much less in flower—invest them with a value which cannot be denied, though to these must ever be added the good attributes of complete hardiness and comparative immunity from

weeks. Division is best done directly flowering is over. In this connection the prostrate habit must be borne in mind, the units so planted as to be half-buried by the soil. Unless this be done, failures will assuredly occur. The species varies considerably, and there are some good varieties. The most brilliant—a vivid crimson indeed—is *W. A. Clark*; next to it, *coccinea*—intense crimson. *Speciosa* (here figured) is one of the largest, and, with *splendens*, two of the richest of the crimson-purple set. *Maxima*, major, *pyrenaica*, and *grandiflora* are other names found in catalogues. Those first mentioned are the best. *Alba* is pure white and quite distinct, its smaller flowers having the petals widely separated to their bases. It is, however, beautiful and very desirable.

E. H. JENKINS.

SOME ROCK GARDEN PLANTS.

[To the Editor of GARDENING ILLUSTRATED.]

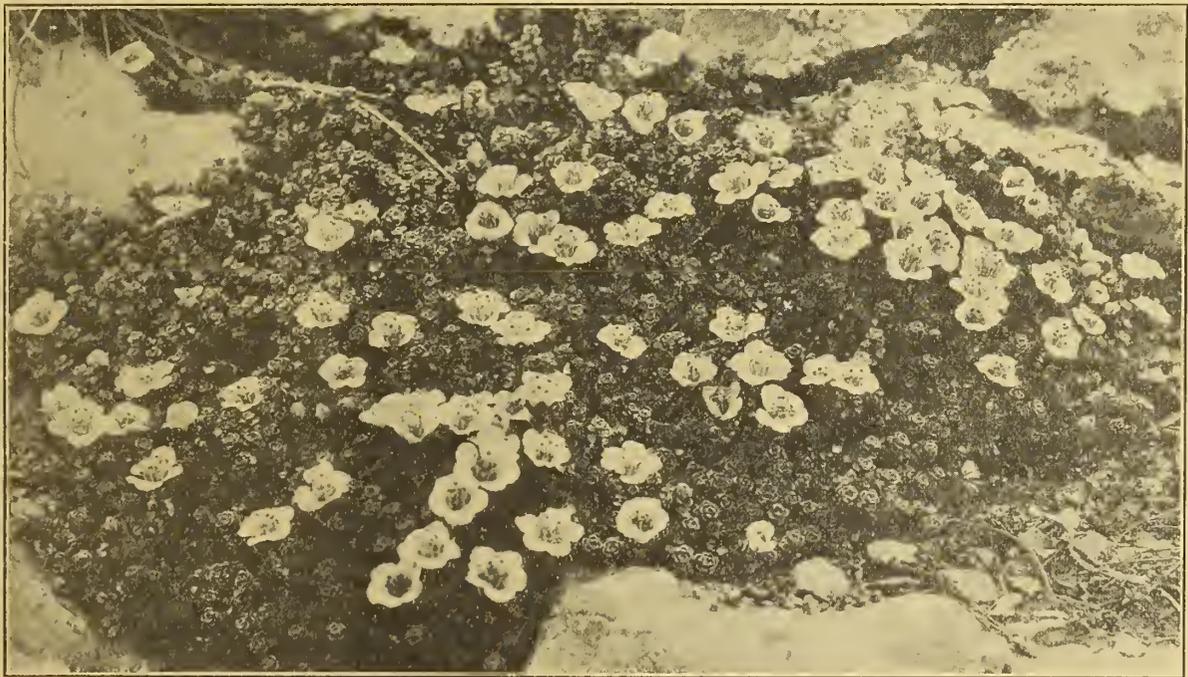

SIR.—In addition to the two dwarf Fuchsias mentioned in your columns a short time ago, there are at least two also worthy of a place in the rock garden.

just above the foliage. They consist of a flat calyx of concave petals, of a soft lavender-blue, resting on a smaller epicalyx of the same shape. From the central ring of white anthers springs the white stigma, with a spreading base. Immediately behind the flower, at the top of the stalk, there are generally two or three diminutive infertile inflorescences of dull purple, at once proclaiming kinship with the Hydrangeas. It is obvious that in one long course of evolutionary change these inflorescences are being discarded altogether, as sometimes there is only one, and occasionally a mere rudimentary attempt. *Deinanthe cerulea* should be planted in a fairly moist situation. A shady spot is imperative, for if the direct rays of the sun fall upon the leaves they speedily become bleached and unsightly; in fact, a fairly dense shade is, as doctors say, indicated for its perfect health and beauty.

T. A. HYDE.

Avonwick, S. Devon.

Cobweb Houseleeks.—Will "E. H. Jenkins," who writes about "Cobweb Houseleeks in pots" in your issue of October 14th, page 515,

Saxifraga oppositifolia speciosa in the Royal Gardens, Kew.

slugs. From the cultural standpoint, soils which are best avoided are those of a hot, sandy nature, and those of an opposite extreme, which are cold and tenacious. Between these the grower will be able to fix a midway line which will bring him a fair amount of success. Aiming at a cool-rooting medium in a position removed from the ill-effects of parching summer heat—always the more to be dreaded where the plants are not under a watchful eye—such a soil would be assisted by a free incorporation of broken sandstone or limestone and firm planting. Very gritty soil and even pure sand are helpful with moisture. Sun and exposure will not harm if the plants are attended to, while sun and partial shade will play a helpful part by extending the season of flowering in any one variety. Mulching, too, is important for permanently planted groups, and done soon after flowering gives new life and assures a growth that will be dowered with blossom in its turn. Propagation by cuttings in spring also ensures increased vitality and a prodigality of blossoming not excelled. In a close, cold-frame, 1/2-inch long bits or rather more root in a few

FUCHSIA PROCUMBENS, from New Zealand, has yellowish, tubular flowers, whose lobes are tinged with purple at the tips. Its leaves are round and small. The entire plant lies close to the ground and stones. Nestling amid the foliage are the remarkable fruits, like a medium-sized Gooseberry, which remain on the creeping twigs for months. They are crimson as they ripen, later on taking a rich, almost turquoise-blue bloom. Another is

FUCHSIA MICROPHYLLA, with tiny bell-like flowers held well away from the red stems, and small green leaves. These are almost upright, of a deep crimson-magenta, with a white stamen. It leads a more or less herbaceous existence in this part of South Devon, springing afresh each season to little more than a foot in height. One of the most interesting and as yet very rare plants comes to us, with so many new treasures, from China—

DEINANTHE CERULEA, a near relative of the Hydrangeas. It is a herbaceous plant, forming a thick tuft of wrinkled, hairy leaves, extremely rough to the touch, and grows about 9 inches high. The flowers are each an inch in diameter and are lifted

kindly say if for rockwork they should remain in the pots which should be sunk in the ground?—CECIL A. P. OSBORNE.

[No; the intention of the note in question was to bring into prominence the special value of these plants to those having very small gardens and probably no other way open to them of growing these very interesting subjects. On rockwork they are seen to the best advantage threading their way, as it were, through large, specially-conceived crevices, or furnishing a sunny, dry slope or ravine composed of half rock, half soil. In these and like places the whiteness of their web—the chief garniture of these plants—is emphasised to the full. On level ground or on rockwork, with too much soil about, much of this characteristic beauty is lost, and in winter is non-existent. Dry overhead conditions and the general absence of soil-damp as felt at ground-level bring out the best attributes in these Houseleeks. In planting break them up or plant single rosettes freely and await results.]

Primula pubescens alba and Daphne Genkwa.—I would be greatly obliged if "E. H. Jenkins" will tell me where I can pro-

cure *Primula pubescens alba* he refers to; also *Daphne Genkwa*? I cannot find either plant in the many catalogues I have by me. I am just now starting a rock garden, and also, if possible, a Heath garden. Can you tell me of any really good work published on Heath gardening?—CECIL A. P. OSBORNE.

[The *Primula* you can get from any hardy plant specialist, while any grower of greenhouse plants would no doubt be able to supply the *Daphne*, which is not hardy. There is no really good work that we know published on the Heath garden. You will find an article on the subject in our issue of August 19th (p. 410), while hardy Heaths are also dealt with in "The English Flower Garden." In your anticipated work in the rock garden you will be well advised in getting outside help and thus avoid the pitfalls into which many amateurs fall.]

Polygonum affine.—The *Polygonum*s are not very choice subjects for the rock garden, being for the most part somewhat coarse, but this species looks quite pretty just now—a pleasing effect being produced by the contrast between the old flowering spikes, which are of a rich reddish-brown colour, and the younger ones, which are pink. It spreads very fast, and needs to be watched carefully to prevent its swamping other things. It is not at all particular as to soil or situation.—W. O.

VEGETABLES.

NOTES AND REPLIES.

Greened Potatoes.—I have been unfortunate as to some King Edward Potatoes. I dug them up, and was called away from home, and they have been lying two weeks on the ground. A man has just got them under cover for me. I would like to know whether it is true that Potatoes are poisonous for table use after they have got a bit green. I do not want to use them as seed as I am getting new Potatoes for seed next year, and I do not want to give them to the pigs when Potatoes are so dear.—HENRY C. W. TOWNEND.

[The greened Potatoes may be safely used. If you lay them out thinly in a dark place and cover them with mats or sacking the green colour, which is due to the exposure to light, will disappear, or you may clamp them in the ordinary way, when the normal colour will again return.]

Brussels Sprouts.—In autumn it is no unusual thing to see growers remove a portion of the lower leaves with a view to induce the plants to produce sprouts. On several occasions I have tried a few plants in a batch, but have never seen any good results from so doing. It is worthy of notice how some plants produce sprouts early compared to others. The many so-called sorts are nothing but selections. Everyone who has grown "Imported" must have noticed how varied the plants are. I am convinced no green crop pays to rogue more than Brussels Sprouts. During September I could not notice how early some plants were developing sprouts. I sowed where they were to stand to avoid labour in planting out. The plants have short glaucous leaves, with nothing of the Savoy kind of foliage. For years I have observed all of this type produced early sprouts of that nice, hard, close kind which are of so much better flavour than the big ones. During the past two seasons I have found that by sowing early in March in the open where they are to remain the sprouts come much earlier into use. If the soil is not rich the growth is firm. Removing the tops and the foliage I consider a mistake, seeing both help to protect the stems in severe weather.—J. C. F. C.

[This idea of sowing Cabbages, Brussels Sprouts, etc., where they are to stand is quite opposed to all the tenets of good gardening. From our correspondent's

note, it seems that all the plants are allowed to stand, no thinning being done, or are we to understand that he sows single seeds in lines at the same distance apart as would be done were the seedlings planted out in the usual way.—ED.]

Potatoes are badly diseased in this locality. If not already completed, the lifting of the tubers should be pressed forward with all the speed possible, there being nothing to be gained by leaving them longer in the ground. As wet weather may now be expected, the effects would be disastrous. Those that were clamped some time ago have become diseased, and it is necessary to examine the tubers in the clamps and reject all that are unsound. Keep the ridges protected from heavy rains by means of tarpaulins or other suitable material. Sprinkle lime freely amongst the tubers, as advised in former notes.—F. W. G., Northants.

Late Potatoes.—Of these there is but a very moderate crop—moderate, that is, as regards the size of individual tubers. Disease, although present, was not alarmingly noticeable; and the best returns during the present year have been given by Up-to-Date and by British Queen. A long line of Langworthy, planted from home-grown seed, hardly repaid the labour of lifting. This variety was planted experimentally. It has previously failed here, but was given another trial, but will now be permanently dispensed with.—KIRKCUDBRIGHT.

GARDEN FOOD.

WHY EAT MEAT?

THAT the vegetable kingdom does furnish a diet of sufficient quality to keep the body at the highest point of efficiency is witnessed by more than half of the human race and almost the entire animal kingdom. Most of the manual work in the world is performed by men and women whose food is obtained from plant life, with a total or nearly total absence of meat. This proves that vegetable foods are force and heat producers and tissue builders.

Many of the cereals are not only rich in proteid and starch, but some of them contain considerable fat. Oats have over 6 per cent. of fat, and Corn about 5 per cent.; while Wheat, Rye, and Barley have about 2 per cent. The fat of the body is estimated at about one-fifth of the total weight. It is evident that this indispensable foodstuff is abundantly supplied in Nuts, ripe Olives, and some of the cereals. Furthermore, Nature has lavished upon mankind a marvellous variety of the most delicious fruits, which are indispensable to the healthy body. While with a few exceptions they do not possess a high nutritive value, they are rich in acids, sugars, and mineral salts, all of which are needed in the body.

Plants are the natural food builders. In these natural foods there are no products of disintegration or waste such as are found in flesh foods. Furthermore, plant foods are always built up under healthful conditions, whereas meat may be diseased during the entire life of the animal, or made so by the conditions incident to slaughter. The process of life in the animal tears food down or breaks it up into its elements again, and then forms it into a more complex molecule, but more unsuitable for food, because of the waste products held within its structure. Vegetable foods tax the excretory organs less than a meat diet, and require less oxygen in their oxidation, and hence have a tendency to increase the duration of life, as their conversion into brain, bone, and muscle is accomplished at a less expenditure of energy. A flesh diet increases the quantity of urates, sulphates, and other waste products, hence increasing the work of the kidneys.

The consumption of meat increases the

function of uric acid and its antecedents in the blood and tissues of the body, which are well-recognised factors in many chronic diseases. Moreover, meat diminishes the alkalinity of the blood and increases the acidity of the urine. Fruits and cereals increase the alkalinity of the blood and also of the urine, an important factor in the prevention of disease. Sir Henry Thompson says, "It is a vulgar error to regard meat in any form necessary to life." Again, "To many it (meat) has become partially desirable only by the force of habit, and because their digestive organs have thus been trained to deal with it." Then he says, "A preference for the high flavours and stimulating scents peculiar to the flesh of vertebrate animals mostly subsides after a fair trial of milder foods when supplied in variety." This variety can be found in the list of cereals, vegetables, fruits, and Nuts. When a well-balanced diet of these foods is partaken of there is no desire for meat. Usually, when there is a craving for flesh foods after once having given them up it is because the body is not receiving sufficient proteid, fat, or salts.

Nature amply furnishes man with food of sufficient quality, quantity, and variety to meet all the needs of the body under all circumstances and conditions, and when he wisely subsists upon such food he is better off physically, mentally, and morally.—*Herald of the Golden Age.*

NOTES AND REPLIES.

Plum Coe's Golden Drop.—The value of the Plum for dessert is so great that the season ought to be prolonged as much as possible. This can be done by planting suitable varieties, and one of the best—if not, indeed, the very best—of late Plums is Coe's Golden Drop. This excellent variety needs a wall, and as it ripens well in such a position during late September and early October its value is evident. Of moderate size, the flavour is first-rate, and it is, in addition, a free-stone, which makes it more valuable. It is a consistent and heavy bearer. I cannot recall a failure with this variety during the past twenty-one years. The tree is of moderate growth, and does not need anything severe in the way of pruning. There is a red variety which is equally useful. Other good late Plums are Reine Claude de Bavay and Wyedale, the latter hanging until November. Pond's Seedling is also useful when thoroughly ripe, but, strictly speaking, it is a cooking Plum.—KIRK.

Squashes as food.—Have any of your readers grown these as the Americans do? In their nature like a large Marrow, they are more fitted for winter storing, and give a fine supply of food. Will our climate perfect their growth? The French make a good use of a like series, of which the Potiron rouge is the largest. Are we not mistaken in neglecting such valuable and easily grown sources of food? Some cottagers use old Marrows in a like way. Can any of your readers kindly tell us of any trials in this way?—HANTS.

Honey as a flavouring addition.—One of my friends recommends honey for sweetening when making jam. The other day he told me that a little touch of honey, eaten along with Black Currant jam, gave a delicious result. An Apple which is somewhat too sharp for the palate when eaten raw may be made quite acceptable when just tipped with honey. I recently tried raw Tomato with a touch of honey, eaten with brown bread-and-butter, and liked it.—J. N.

The Potato Onion.—This should be more generally grown. It has a mild, agreeable flavour, and would be welcomed by many people who like the Onion but who for various reasons avoid it. The Potato Onion has such a mild flavour and is so easily digested that many prefer it.—J. N.

TREES AND SHRUBS.

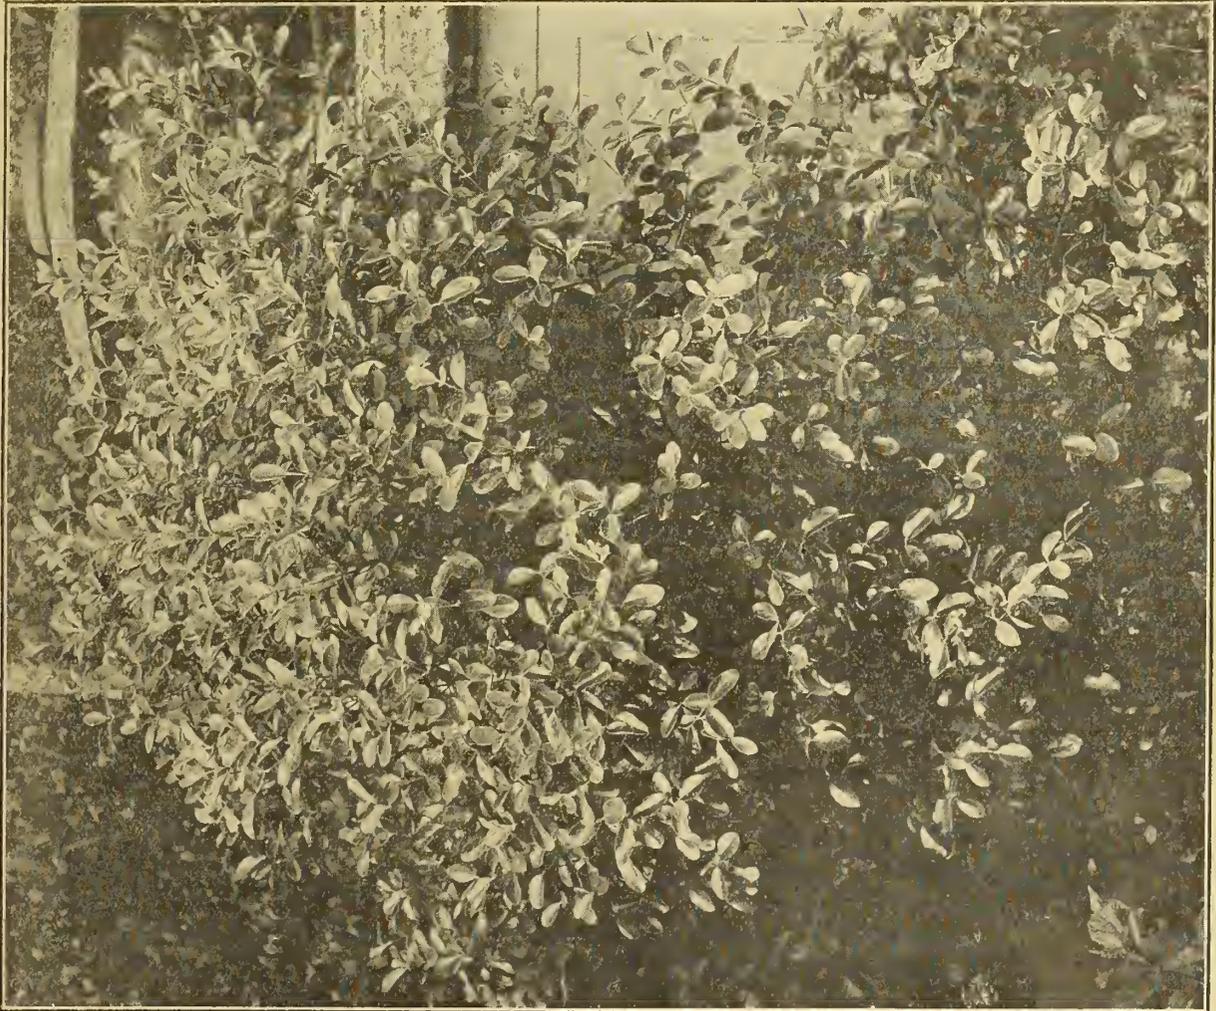

FEIJOA SELLOWIANA.

This handsome shrub has created a good deal of interest, for, although a native of S. Brazil and Uruguay, it is quite hardy when planted against a wall with a south, west, or east aspect, in many parts of the British Isles. Originally discovered in 1819, little appears to have been known of the plant in this country before 1895, but it is now fairly common. In Brazil it forms a large bush, its chief interest lying in its edible, Guava-like fruit. Here it grows 10 feet or more high when planted against a wall, and is of interest as an evergreen, for its dark green, oblong leaves, with white under-surface, are re-

flavour. It is well worth growing for the sake of its flowers, which are each about 2 inches across, and composed of four fleshy petals of a curiously hooded shape. These petals are purplish inside, and almost white on the exterior, but owing to their hooded shape the interior is almost hidden by the incurving of the edges, thus exposing the paler tinted outside. Like many other members of the Myrtle family, the long, slender filaments in the centre of the flower form a notable feature of the inflorescence. In the case of this Feijoa they are bright red tipped with yellow. The temperature of a warm greenhouse or intermediate structure suits it best. A native of Brazil and Uruguay, Feijoa Sellowiana was introduced by M. Edouard André in 1895.

leaves were unfolding, they were attacked by myriads of aphides, which, if left undisturbed, would soon disfigure them. A syringing with a mixture of soft soap and an infusion of quassia chips made short work of these pests. Strange to say, I never saw these aphides on any other plants except this Fatsia. The value of the Fatsia as an ornamental plant for the dwelling-house is considerable, as, owing to its hardiness and the stout, leathery nature of its leaves, it stands exposure to draughts well. When too large for this purpose it can be planted out. This should be done in early summer, so that the plants may be well established before winter.—W. T.

Hydrangea Sargentiana.—The most remarkable feature of this plant is the huge size of

Feijoa Sellowiana at Myddelton House, Waltham Cross, N.

tained throughout the year. Moreover, it bears handsome flowers freely. Each flower is about 2 inches across and produced singly from a leaf-axil. The sepals are white, as also are the outsides of the petals, the inside being blood-red. The stamens are each an inch or so long and red. Altogether it is a very showy flower. Unfortunately, the fruits are not perfected, or only on rare occasions here. It thrives in ordinary good garden soil, but likes a little peat about its roots. Cuttings of young shoots root readily in a warm and close frame in summer. In some favoured localities it can be grown as a bush in the open ground. D.

—This, a member of the Myrtle family, is very nearly related to the Guava (*Psidium*). The fruit is said to be egg-shaped, and of a delicious, aromatic, spicy

NOTES AND REPLIES.

Fatsia japonica.—In a note on this shrub in GARDENING ILLUSTRATED, October 14th, attention is directed to the fact that it is of considerable value as a hardy evergreen. It has another recommendation, and that is its value for smoky towns. I was long resident in a congested district of London, and, having a couple of plants that had become too large, they were planted in a front garden where little sunshine or fresh air fell to their share. Still, they did remarkably well, and pushed up numerous suckers. For some years before I left, the creamy-white flowers were each autumn freely borne. The atmosphere, being so smoke-laden, I used to sponge the leaves over in the spring when the fogs were over. A singular feature was that each year, just as the crowns of young

the leaves on the barren or non-flowering shoots. These are each 10 inches or 12 inches long and 7 inches or 8 inches wide, dark green and densely hairy above and paler and bristly below. The shoots, too, are thickly furnished with hairs and bristles, giving the plant altogether a remarkable appearance. On the flowering shoots the leaves are smaller, but the large flat corymb of flowers compensates for this. The fertile flowers are lilac-coloured and occupy the centre of the corymb, while an outer fringe is formed by the sterile flowers composed of large showy petals of a pale pink colour.—*Irish Gardening*.

Garrya elliptica.—Looking round the other day I was struck by the excellent promise given by a piece of *Garrya elliptica* upon a wall. The piece in question usually does very well, but it seems to have been suited in a special degree by the damp season. One of the most attractive of the catkin bearers, it ought to be borne in mind by intending planters

that there are two forms of *G. elliptica*. Of these, the male form is much more attractive than the female, the catkins being not only larger, but much more graceful than are those of the female plant.—W. McG.

ROSES.

Treatment of Cabbage Rose in pot.—Please tell me how to treat a Cabbage Rose slowly recovering from accidental over-watering in July. It is in a 12-inch pot. It was doing well, and had fourteen buds showing colour when I had to go away for a week, early in July. On my return it was covered with black-fly and every bud was yellow, soft, and rotten inside. I stirred a little ground lime into the top-soil, and kept this well open, and it recovered enough to emit fresh leaves (all the old ones fell) and to make some new shoots, but they are thin. I am anxious to keep it in a pot, as I have only a little, walled, flagstone garden, and only five or six hours' sun from March to end of October. Before this accident I was feeding it with liquid artificial manure. I have had to fight caterpillars, and have managed to keep it fairly clear of them.—M. DE C.

[Many reasons might be urged against growing this in a pot at all, but that is not the point. You say it "was doing so well," though the puny-sized growth you sketch proves it to be in a very poor way. Planted last November, if in good soil and properly done—these are important items in this connection—and all had gone well, it should require nothing more than top-dressing now. Being now so feeble we should have it repotted in good, loamy soil, shaking away the bulk of the old soil which frequent waterings may have rendered stale or even sour. Add a dusting of bone-meal to the soil or some old mortar-rubble if available, and make sure the drainage is perfect. When potted it would be best plunged in ashes or Cocoanut fibre to the rim. At the end of March next have it pruned hard back to good dormant eyes to induce a new and more vigorous growth. As the plant is suffering from overwatering, repotting in fresh soil is the only remedy.]

Repotting Orleans Rose.—Please tell me whether I should shift now or in March a half standard Orleans Rose which came established in a pot during this summer? It is in an 8-inch pot, and has done well. Would a 12-inch pot be too big a shift? I have only a little, walled, flagstone garden, and should like to keep it in a pot. Please tell me how best to protect it from frost? I have no shelter of any kind, and the garden only gets an hour's sun in the mornings from November to February; but the rest of the year a good five or six hours.—M. de C.

[Shift, *i.e.*, repot, the standard Orleans Rose now, reducing the old ball of earth at least one-half and repotting in good, fibrous loam to which well-decayed stable-manure and a little bone-meal and sand have been added. Healthy Roses like rich food. Good drainage and firm potting are essential. The 12-inch pot will not be too large. Let it be perfectly clean and dry. Place it in a sheltered corner of the garden, plunging the pot to the rim in ashes or other material. It will need no other protection. Take care, however, it does not suffer from root dryness in consequence. October is the month of new root production in the Rose, and at this season, or near, the plants readily respond to intelligent treatment. If you do not possess the right soil get a nurseryman to supply some or pot the plants correctly for you.]

The Orleans Rose and mildew.—This Rose has proved practically immune to mildew, which has been troublesome this year in many gardens, and has deprived the plants of much of their value and beauty. The Orleans Rose has done exceedingly well, and has produced a wealth of excellent flowers of that glowing red often called "Geranium red."—S. A.

OUTDOOR PLANTS.

FROM NEW ENGLAND.

ABOUT your creeping Fern. I wrote the specialist in our native Ferns, who took my order last April to pot and properly root some plants and to send them to me at once, as I wished to carefully re-pack them for their long journey to England. Can you imagine my feelings when he replied that, owing to the very bad season, he had not been able to get plants that were sufficiently strong to survive the journey. Do not despair, you shall have them. That you may be assured of my interest, there is being sent to you by the ship that takes this letter a box containing the following plants, which I hope will reach you in good condition and thrive in their new home. They are as follows:—*Cypripedium acaule* (showy Lady's Slipper), plant under thin Pine woods in a rather dry and mossy place in leaf-mould; colour, lovely pink. *C. pubescens* (yellow streaked with purple, very handsome). *C. Regina* (pink and white, large and beautiful), these last in partial shade near the foot of a bank; also in leaf-mould. Blackberry Lily (*Belamcanda chinensis*), a Chinese plant escaped from cultivation, probably brought to New England from China by sailors in the last century; blooms here in late July and August. Give it a dry situation. It does well in rock crevices. *Hepatica*, one of our loveliest little spring flowers. Plant also among rocks. Jack-in-the-Pulpit (*Arisaema triphyllum*), shady place in leaf-mould.

I wish you could see the autumn flowers in the meadow, about 8 acres in extent, with two brooks running through it, great trees surrounding it, and Grass paths crossing it. These are some of the flowers in full bloom at present and growing by the thousand:—Blue Veronica, Iron Weed (*Vernonia*), Joe Pye Wood (*Eupatorium purpureum*), Golden Rod in twenty varieties, many varieties of hardy Asters, Bone Set (*Eupatorium perfoliatum*), many varieties of *Heleniums* and *Helianthus*, *Boltonia*, *Phlox* (naturalised, white, dull pink, and purple), *Turtle-head* (*Chelone*), *Giant Arrow-head*, *Pickrel Weed* (*Pontederia*), *Red Lobelia* (*Cardinal Flower*) and blue *Lobelia*, white *Snake-root* (*Eupatorium ageratoides*), *Purple Loosestripe*, *Jewel Weed* (*Impatiens biflora*), *Tansy*, *Water Forget-me-not*, *Fringed Gentian*, *Bottle Gentian*, *Deptford Pink*, *Wild Carrot*, *Bouncing Bet* (*Saponaria officinalis*), with *Cacti* and *Sedum spectabile* on the rocks.

P.S.—Just after writing the above I have been informed by the forwarding agents to whom I took the box of plants referred to above that Great Britain had passed a law forbidding the importation of all "luxuries" during the war, and that plants came under the head of "Luxuries," and could not be imported. This, because there are so few ships at present, and all possible space needed for necessities.

The plants will be cared for and sent on when the war is over. They will be planted in a little corner and called "Your Garden." H. R. F.

NOTES AND REPLIES.

Carnations failing.—Two months since my Carnations were in a frame, looking very robust and healthy. A fresh gardener moved them a month ago into unheated conservatory. They are gradually becoming light in colour and drawn. Can you suggest the treatment they should have and if any stimulant is necessary? I cannot say if they have had any feeding.—K. B.

[If you are referring to hardy border sorts layered a few weeks since and recently potted up, the plants would have

been infinitely better in the far more congenial conditions of a cold frame, where, on a cool ash bed near the glass and with ample air available, they would be more likely to receive correct treatment. A "moderately cool house" is quite unsuitable, and a cold frame in sunny aspect is to be preferred to even a cold house. For these the treatment is obviously wrong, and the remedy is to return them to the frame, where a more rational treatment could be meted out to them. If, however, you are referring to perpetual sorts grown for winter flowering, you had better send fuller particulars, among which size and age are important. You should send full name—see rules.]

Iris not flowering.—Please tell me what can be the reason of the common purple Iris not flowering with me, while it does so well in every London garden? Five years ago I bought three or four of these, and one pale primrose one. This latter flowers regularly and well, but the more ordinary purple has refused to do so for the last three years. In the autumn of 1914 they were all transplanted nearer the sunny end of my little, walled, flagstone garden. Can it be that the soil here is too light? It is near some Orange Lilies, and these and the primrose Iris and a deeper yellow *Antirrhinum* should have made a charming group. The purple Iris looks exceedingly healthy, with great, strong leaves, of a beautiful grey-green, with a kind of shimmer on them. Do these Irises like lime or not?—M. DE C.

[This is most unusual and not possible of determination from your letter. We should, indeed, look for a good flowering next year from plants that now look "exceedingly healthy" and have "great, strong leaves of a beautiful grey-green," all of which is quite consistent with health and vigour. As a rule, the plant is so indifferent to soils, not liking those of a very retentive nature, however, but succeeding well in most others. Lime is favoured by all the Flag Irises, and many other species and hybrids like it, too, and you will not err in adding some to the soil, scattering it thereon and pricking it in with a hand-fork. It may be given in the powdered form or by way of bone-meal, well dusting the surface over with either and pricking it in. Ordinarily light soils suit the plant well—the good growth you speak of proves this—hence we imagine there is not much wrong here. Do not disturb the plants.]

Ceratostigma Willmottianum.—This flowers freely from August onwards until cut by frost, which in sheltered positions may not be until November or December. It is also valuable cultivated in pots for the cool greenhouse, growing the plants outside during the summer, and bringing them under glass when flowering commences. The colour of the blooms may be likened to that of *Plumbago capensis*. It is a much more robust species than the older plant, *C. plumbaginoides* (syn. *Plumbago Larpente*). Plants in Miss Willmott's garden have reached a height of 5 feet, but at Kew the growths were cut back last November. The plants, however, pushed up young shoots freely from the base in spring, and are now very bushy plants, 2 feet to 2½ feet in height. The soil should be well drained and comparatively light, a mixture of peat, leaf-mould, and coarse sand mixed with most garden soils being suitable.—*Irish Gardening*.

The European Dog's-tooth Violets.—May I put in a plea for the European Dog's-tooth Violet, which may still be planted and is one of the prettiest of our dwarf hardy flowers? It is cheap, easy to grow in sun or semi-shade, and, when it does well, gives many of its charming flowers above its mottled leaves. I like to plant with the crowns about 2 inches below the

surface and in any common soil. By the way, some people plant the tubers the wrong side up. They should be set with the broad or blunt end up, the sharp one below. *Erythronium Dens-canis* is to be had in various colours, purple, pink, almost red, rose, and white. Mixed varieties can also be bought. The grandiflorum strain is the finest, and selected varieties under name may be procured at a small additional cost.—S. A.

LILIUM GIGANTEUM.

This fine species from the Himalayas is worth the attention of all hardy plant lovers. When in flower no finer or more handsome plant could be found in any garden. The weak point of the plant is that one can never say when a good flowering may occur. To this uncertainty has to be added the fact that the plant flowers

depends upon individual size and progress. Those who do not mind waiting should raise seedlings and plant them when three years old into their permanent positions, selecting a place among low shrubs, as *Kalmias*, *Heaths*, *Andromedas*, etc. When planting, the bulbs should be inserted about 6 inches deep in the soil, which should be first deeply trenched and heavily manured. The finest development of the plant is seen in the more sheltered and warm districts, but it is not unusual for the plant to reach the same perfection in localities quite the opposite. Where the more mature bulbs are being planted, those of three years or four years old are best, and such as these will take three years more before the flowering stage is reached. This lapse of time permits the bulbs to become fully established, and only when this is the case does the plant attain to its

raer, Wigton, who kindly sent us the photograph from which our illustration was prepared, writes as follows:—

The plant produced from the one bulb a stem branching near the base into ten perfect stalks. It produced forty flowers, all normal, as shown in the illustration.

Van Tubergen's Tulip.—This gorgeous species from Bokhara is worth mention for the benefit of those who admire Tulips. The big cup-like flowers, produced in May, are each about 9 inches across and of the most vivid crimson-scarlet, with a big black spot at the base. It received an Award of Merit from the Royal Horticultural Society, and thoroughly well deserved the distinction.—S. ARNOTT.

Epilobium Hectori.—This tiny little carpeter is a native of New Zealand, and has rounded, bronze-coloured foliage. The flowers are white, but insignificant, the whole charm being in the foliage. Where doing well, it runs about and also seeds freely, but with me it does not seem very hardy unless planted in very stony soil.—N. L.

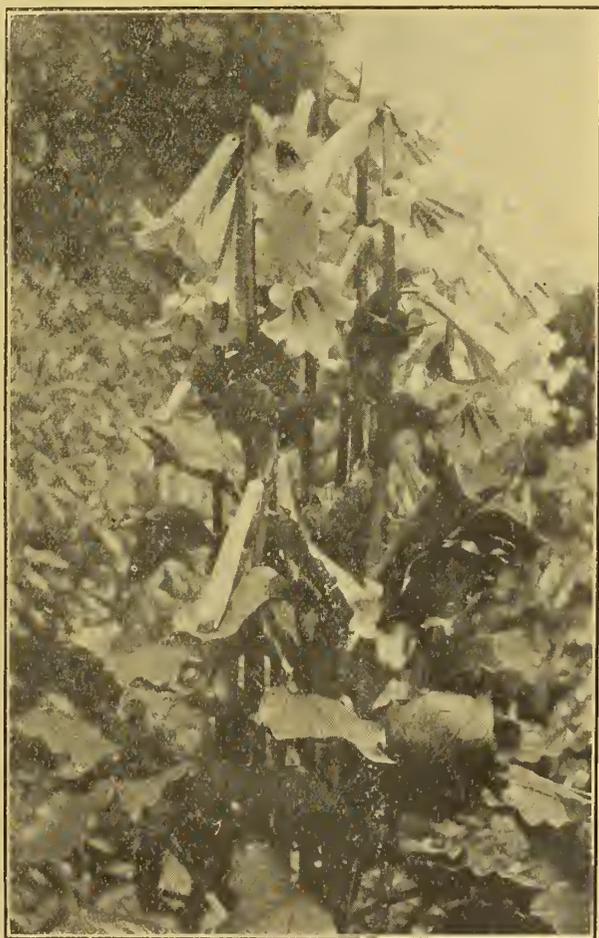

Lychnis Lagascæ.—This, once established, goes on blooming all through the summer. I am still getting plenty of its beautiful delicate pink blossoms at the beginning of October.—N. L.

GARDEN PESTS AND FRIENDS.

NOTES AND REPLIES.

The Wood Leopard Moth (*Zeuzera æsculi*).—I am sending you a piece of a Crab Apple-tree, in the centre of which I found the caterpillar I enclose. I should be glad if you can give me the name of it and how it became embedded in the tree. I first noticed some small, sawdust-like particles near the base of the tree, and on examining it I found a soft cavity under the bark full of fluid and eggs.—JAMES DENHAM.

[The piece of wood of the Crab Apple tree you send is bored by the caterpillar of the Wood Leopard-moth (*Zeuzera æsculi*), a by no means uncommon insect. The presence of one of these caterpillars in a branch or stem may be detected by finding small sawdust-like particles sticking to the tree where a little moisture is oozing from the bark; on closer examination a small hole will be found from which these particles (which are composed of small pieces of the wood gnawed off by the caterpillar and its droppings) are exuding. The easiest way of killing the inmate is to pass a sharp-pointed wire as far as possible into the hole, which will usually be found to proceed upwards, so as to stab the caterpillar. It can usually be seen, from the appearance of the wire, whether the insect has been reached or not; if by any turn in the tunnel it has not, the entrance to the tunnel should be slightly enlarged, and some cotton-wool or tow soaked in tar or paraffin oil should be pushed in as far as possible to stifle the caterpillar, and the mouth of the hole should then be closed tightly with a plug of clay, so as to keep the smell in. If it is possible to cut off the branch without injury to the tree, you can then, by splitting it open and killing the insect, make sure that it is destroyed. The caterpillar lives for three years before it attains its full growth and becomes a chrysalis, which it does near the mouth of its burrow. The moth is a fine and very elegant insect. The females are considerably larger than the males, and are 1½ inches in length, and measure 2¼ inches across the wings, which are white and almost transparent, with yellowish-brown veins, between which are rows of roundish bluish-black spots. The body is white, with black markings. They may be found in July or August.]

Lilium giganteum at Logan, Stranraer, Wigton.

but once and perishes, and while as a sort of compensation producing offsets to propagate its kind, these latter must be grown for three or more years before they reach a size at which they may be expected to bloom. This, then, is the seamy side of this noble species; but as a set-off against all this there is that unique beauty in the plant when in flower which commands the attention of all, and which renders it so conspicuous an object in the garden.

A good depth of soil, a cool rooting medium, and shelter from frosts for the huge heart-shaped leaves that appear in early spring are among the chief essentials to success. As a rule, the plant produces seeds quite freely, and these may take from seven to ten years to reach the flowering size. The offsets left by the blooming of a plant may, with good treatment, arrive at the flowering stage in three or four years. Much, however, de-

noblest proportions. When fully grown the strongest spikes will tower to a dozen feet in height, and in such instances the giant stature, usually accompanied by a flowering proportionately good, appeals to all. A more frequent height is 7 feet to 10 feet, and then a group or colony in the garden is a most imposing sight. The plant itself is quite hardy—i.e., the root and bulb—but the fresh leaf growth which develops quite early in spring is apt to be cut by frost or by biting winds. In these circumstances, therefore, it is advisable to plant where shelter to the leafage can be given, and a western exposure with banks of shrubs or evergreens sheltering from the north and east is the best position in which to grow the plants. This question of position is important, inasmuch as if the foliage be much injured by frosts the plant will take longer before it flowers.

Mr. Kenneth McDouall, Logan, Stran-

THE WEEK'S WORK.

OPEN-AIR GARDENING.

IN BLOOM OCTOBER 18TH.—*Abelia rupestris*, *Choisya ternata*, *Hydrangea paniculata grandiflora*, *Ceanothus* (in variety), *Escallonia* *Edinburgh*, *E. mon' idensis*, *Hardy Fuchsias* (in variety), *Osmanthus ilicifolius*, *Berberis nepalensis*, *Laurustinus*, *Genista tinctoria*, *Spartium junceum*, *Solanum jasminoides*, *Magnolia grandiflora*, *Jasminum nudiflorum*, *Hamamelis virginica*, *Veronicas* (in variety), *Myrtle*, *Spiræa Thunbergi*, *Lavatera Olbia*, *Polygala Chamæbuxus purpurea*, *Polygonums*, *Senecio Greyi*, *Nierembergia frutescens*, *Phygelius capensis*, *Michaelmas Daisies* (in great variety), *Acanthus*, (*Enocheras* (in variety), *Anemone japonica* (in variety), *Plumbago Larpentæ*, *Sedum Sieboldi*, *S. spectabile*, *Lobelia cardinalis* (in variety), *Achillea Eupatorium*, *Linum arboreum*, *Tritomas*, *Francosas*, *Pentstemons* (in variety), *Antirrhinums*, *East Lothian Stocks*, *Scabiosa* (in variety), *Nemesis*, *Petunias*, *Pelargoniums* (in variety), *Ageratum*, *Cannas*, *Begonias*, *Salvia azurea grandiflora*, *S. Greigi*, *Tufted Pansies* (in variety), *Gazania splendens*, *Ethionemas*, *Heeria elegans*, *Convolvulus mauritanicus*, *Potentillas*, *Helianthemums*, *Tropæolum speciosum*, *Clematis* (in variety), *Polyantha* and *Climbing Roses*, *Ericas* (in variety), *Menziesias*, *Erigeron mucronatus*, *Polyanthus*, *Myosotis*, *Hardy Cyclamens*, *Sternbergia lutea*, *Crocus speciosus*, *Belladonna Lilies*, *Violets* (in variety).

Many trees and shrubs are now conspicuous for their coloured foliage, among them being: *Azaleas*, *Berberis Thunbergi*, *Rhus* (in variety), *Parrotia persica*, *Cockspur Thorn*, *Liquidambar*, *Cornus* (in variety), *Viburnums*, *Ame-lanchier*, *Akebia quinata*, *Vitis* (in variety), *Actinidia arguta*, *Maples* (in variety), *Quercus coccinea*, *Willows*, *Canadian Poplar*.

WORK OF THE WEEK.—Climbers on walls were gone over during the week, cutting out all dead wood, and tying in growths where necessary. These are not tied too tightly, but allowed to extend out from the wall, which gives the plants a more natural appearance. Just sufficient ties to keep them in position are all that are required. The present is a good time to plant such climbers as *Wistaria*, *Lonicera*, *Polygonum*, *Solanum*, *Azara*, *Jasminum*, *Vitis*, *Berberidopsis corallina*, *Forsythia*, and many others. Before planting, the soil should be deeply dug and some manure and fresh soil added. *Montbretias* are now being taken up, stored in boxes, and placed in cold frames for the winter. I do not dry them off, but allow them to grow, dividing them in February, again planting them in boxes, encouraging them to grow as much as possible, and planting out in April. It is impossible to over-rate the value of the *Monthretia* for late summer and autumn. Some late-flowering varieties even extend the blooming season well into October. Seeds of many perennials, alpine, and rock plants, sown as described on page 417, have germinated freely. Many of the seedlings have been pricked out into boxes filled with finely-sifted sandy soil, and placed in a cold frame. The rock garden is being cleaned and weeded. Where the roots of coarse weeds are underneath the cultivated plants it is in some cases necessary to lift the plants to get every bit of weed root out of the soil. Following the cleaning and weeding, a top-dressing is applied to most of the plants, using a mixture of loam, leaf-mould, and granite chippings, first screening all these through a ½-inch sieve. Plants that are easily injured by damp will now be protected by placing squares of glass or small hand-lights over them to keep off the wet. Many of the hardier plants, such as *Dianthus* species and varieties, *Saxifrages*, etc., raised from cuttings this season, will now be planted in their permanent positions. Others will be kept in cold frames through the winter and planted out early in the spring. As some plants become overgrown after a few years, it is necessary to replant them. For this purpose young plants raised from cuttings are much better than pieces obtained by division. *Michaelmas Daisies* have been a great attraction for the last month. The best varieties may be increased by division as soon as the plants have

finished flowering, or they may be propagated from the young growths which the clumps freely produce in spring. The plants should be examined when in flower, selecting the best and most distinct varieties, discarding all inferior kinds. F. W. GALLOW.

Lilford Hall Gardens, Oundle, Northants.

SOUTHERN COUNTIES.

Late Potatoes.—These must now be lifted as the tops are decaying fast. If the weather continues wet much loss of tubers is likely to ensue. The crop, as far as can be ascertained, is good. The ware, or those tubers intended for eating, should either be put into the Potato store or be clamped outdoors in a conveniently situated and dry spot. The seed-tubers, which should be picked up after the ware has been stored, should be laid out thinly in a cool, dry, frost-proof place, where they can remain dormant until the time arrives for placing them in boxes to give them a start prior to planting in spring.

Spring Cabbage.—There being an abundance of plants on hand, a further large breadth of varieties such as *Harbinger*, *Ellam's*, *Matchless*, *Johnson's First-crop*, and *Nonpareil* is being planted. Previously set-out breadths require constant attention, as slugs are very numerous and destructive. Rings formed of ashes and lime, round, but not touching, the stem of each plant, act as a good preservative, but need to be renewed frequently until the plants start growing freely. To keep down weeds is a troublesome matter just now, as the surface is too wet for hoeing to be profitably done. Until the weather allows of hoeing taking place, the largest of the weeds must be pulled up by hand, paying particular attention to *Groundsel* in this respect.

General work.—There is much that wants attending to now in the kitchen garden to render it tidy until digging commences. All exhausted crops, such as old Cabbage and Cauliflower stumps, need pulling up and the ground afterwards cleaned of weeds, etc. Peas which have finished cropping should be pulled up, and if the sticks are of no further use they and the haulm and weeds can be burnt on the spot. French Beans no longer serviceable should be got rid of, Carrots lifted and stored for the winter in dry sand or soil in the root store, *Ruhharb* and *Seakale* for early forcing cleared of decaying tops, and *Globe Artichokes* made ready for affording protection as soon as it becomes necessary. Winter Onions need to be hand-weeded and the ground between the rows afterwards hoed through, and the same with regard to Lettuces, which will remain in the drills throughout the winter. A good quantity of plants raised from the first sowing must now be planted at the foot of walls facing south and west, or in any other sheltered position to stand the winter. The *Hardy White* and *Bath Brown Cos* are very hardy, and will stand a fair amount of frost with impunity. Cauliflower plants to stand the winter must now be pricked off into frames where this has not already had attention.

Outdoor Peach-trees.—Shortage of labour having prevented these from being attended to as they should have been during the summer months, the young wood is now being fastened back to the wall so that it may receive the full benefit of autumnal sunshine. As the work proceeds surplus growths are dispensed with, and a distance of at least 6 inches allowed between the shoots retained, with a view to giving them a chance to become properly ripened. The few fruits now remaining on the late varieties are best utilised for the making of compotes, etc., as it is doubtful if they will ever become sufficiently ripe for the dessert. Other fruit-trees will now receive a final look over, cutting back all secondary growths on spurs both on walls and trees in the open. In the former case leading shoots will be lightly tacked in to be finally dealt with when winter arrives; and in the latter case they will be shortened about one-third. Figs must be relieved of partly-developed fruits, as these will not come to maturity this season, neither will they be of any use for next year.

Fruit-gathering.—With the exception of the very latest varieties, Apples and Pears should now be carefully gathered and stored, laying them out as thinly as circumstances permit in the case of Apples, and in single layers only in the case of Pears.

Herbaceous borders.—The beauty of these is fast waning, and work in the nature of rearranging or the formation of others elsewhere can soon be undertaken. In the first instance, all choice subjects and such things as will not be readily recognised after the tops are removed should be labelled before lifting. The plants as they are dug up should be laid in temporarily in some convenient spot. After all are lifted it is a good plan when creeper-covered walls form a backing to the borders to put these in order before the border is dug. If the latter has not been done within the last four or five years it should not only be double dug or "bastard trenched," but be thoroughly well manured. Before replanting, divide the clumps of all subjects which stand in need of it, and select for planting the outer portions only. From five to seven pieces will form a good clump or group of any one subject. A greater number is admissible when good, bold groups are required or when the borders are of a good width and proportionate length. Planting single plants of any one thing should be avoided as a "spotty" effect results and the beauty of the border is spoilt. Spaces for the planting or sowing of appropriate biennials and annuals may be left vacant along the front of the borders. Colour arrangement is, as a rule, governed by individual taste; all the same, care should be taken that when in flower the border forms a harmonious whole.

Michaelmas Daisies.—The plants as they pass out of flower should be cut down and the border made as tidy as possible. Notes should have been made ere this as to any alterations that may be required, also the situations for the planting of the more recent introductions, if such are to be acquired. Replanting may be done after the late-flowering varieties are past their best, but deferring the matter till next February is better.

Border Chrysanthemums.—The borders require much the same attention as the foregoing to keep them tidy. Care must be taken that the labels do not get misplaced or much confusion may ensue next year.

Heath garden.—This requires a general look over, pulling up weeds where necessary, cutting the long Grass between the breadths or beds of each variety and rendering the whole as attractive as possible.

Rock garden.—This needs a general look over, and should now be put in order for the winter. Any replanting or alterations may also be carried out at the present time and the formation of new rockwork undertaken.

Planting.—As there are now many vacancies in the front portions of mixed flower borders owing to the dying off of annuals and biennials, the same should be filled with *Wall-flowers*, *Sweet Williams*, *Canterbury Bells*, *Myosotis*, *Arahis*, *Aubrietias* in variety, *Silene*, etc. As the beauty of hedging plants is fast fading, the beds should be gradually filled with their winter occupants. Planted in good time, these have a much better opportunity of getting established before winter sets in than when not set out till the beginning of next month. Pansies for making a display in the spring should be planted without delay about 9 inches apart each way.

Belladonna Lilies.—These are now making a fine show, and to prevent wind and rain damaging the hoods, provision should be made for stretching a length of canvas over them when occasion arises for giving protection. This small amount of attention will considerably prolong the display.

Arum Lilies.—If not already housed, the plants should without delay be taken under cover. The forwardest plants—if spathes are wanted early—may be put into slight warmth only for the present. The remainder should be kept as cool as possible.

Hippeastrum.—The foliage having in most cases died down, the pots may now be stood on a shelf or stage in a vinery until the time arrives for shaking out and re-potting the bulbs in spring. A. W.

MIDLAND COUNTIES.

Peach-houses.—In houses where the wood is still green, a little fire-heat is afforded to assist the wood to ripen. In the early house the wood is sufficiently well ripened, and preparations will now be made for a fresh start. As the shoots were thinned at the time the fruits were gathered and only sufficient retained for furnishing next season's crop, the pruning will merely take the form of removing a few of the older branches to make room for younger shoots. The trees are loosened from the trellis, and the base of the stems well scrubbed with Gishurst compound. For the smaller branches a soft brush is used, taking care not to damage the buds. The trellis and the wood work are cleansed with soapy water, and the wall washed with hot lime. The borders will then receive attention, removing the top soil to a depth of about 3 inches, replacing it with a top-dressing composed of fresh fibrous loam mixed with lime rubble and a moderate quantity of Le Fruitier.

Tomatoes.—Old plants which have nearly finished cropping have been thrown away, cutting off the few remaining fruits that will ripen. Plants which are swelling their fruits are liberally fed with stimulants, such as liquid-manure from the farmyard, soot-water, and an occasional sprinkling of an artificial manure. Side shoots are removed regularly, and leaves which are likely to prevent the sun ripening the fruits are cut back. Attention to the setting of the fruits on the later plants is necessary, as the flowers do not set freely at this time of the year. In bright weather a sharp tap on the stem is sufficient to distribute the pollen, but when the weather is dull and cold the flowers are dusted with a rabbit's-tail. A free circulation of air is maintained avoiding cold draughts, and sufficient artificial heat is employed to keep the temperature about 60 degs.

Strawberry beds.—The plants should be looked over once more, and any runners found upon them should be cut off. Lightly hoe the surface soil between the plants and remove all weeds and rubbish. Afterwards apply a good mulch of decayed manure. It is essential that this work be done early, in order that the autumn rains may wash the manurial properties from the mulch down to the roots, and so assist the plants to complete the maturing of their crowns before winter sets in.

Planting fruit-trees.—It often happens that planting, rendered necessary by the exhaustion of old trees, is deferred until another season on account of the difficulty in getting the work done. This neglect should be avoided wherever possible, as time and space are wasted on the cultivation of old, exhausted trees. Thorough preparation of the ground is necessary to obtain the best results in fruit culture, and this should be done without delay, so that the trees may be planted during November if the weather is favourable. Trees planted early, while the ground is still warm, will commence root-action at once, and will soon become established. Where young trees are planted in the place of worn-out specimens the soil should be removed entirely and replaced with fresh compost, as the ground will have been exhausted by the older trees. Do not plant in heavy, cold land if it can be avoided. Where the soil is naturally unsuitable, much may be done to improve it by adding road scrapings, lime rubble, wood ashes, and similar materials to render it more porous. In the case of Apples and Pears, manure should not be used at the time of planting, but it may be freely incorporated in the soil when Gooseberries, Currants, and Raspberries are planted. Stone fruits require plenty of calcareous matter in the soil. In the case of wall trees, a layer of lime rubble, broken bricks, or similar material should be placed at the bottom of the trench, which should be from 18 inches to 2 feet deep. As the varieties of Apples are very numerous, only those that succeed in the particular district should be selected, this also applying to Pears. It is a common mistake to plant too many varieties. The first batch of cuttings of

Perpetual-flowering Carnations has been inserted in boxes of washed silver sand. The cuttings are made of strong side shoots, taken off with a heel attached. The sand is

thoroughly soaked with water and the cuttings are simply pushed into it. The temperature of the pit in which the cutting-boxes are placed is about 60 degs. The sand is kept thoroughly moist until roots are formed, when the plants will be transferred to thumb pots filled with a sandy compost. In this locality cuttings rooted at this time of year give better results than those rooted in January or February. In the south, those rooted in January or February are preferable. Pelargonium cuttings which were rooted in boxes out-of-doors have been removed to a cool house, the boxes being elevated as near to the glass as possible. Abundance of air is given in favourable weather.

Late Cauliflowers of the Autumn Giant type should not be exposed to the weather or their value may be considerably lessened. The usual method of protection by placing a few of the plant's own leaves carefully over each head will be sufficient to keep off a few degrees of frost. If unheated pits or frames are available, the very late plants should be lifted with a good ball of earth attached to the roots, and planted fairly close together in them. Give a good watering immediately after the planting has been done. In favourable weather admit all the air possible to the plants. Under this treatment good Cauliflowers may often be obtained until the middle of winter.

Autumn Broccoli.—Owing to the mildness of the season the plants are "turning in" earlier than usual. These need to be closely watched, it being necessary to protect them from frost by covering the curds with leaves and by tying up closely together the outer leaves. In order to keep up a supply as long as possible some of them may be lifted with a good ball of soil and replanted at half their usual distance apart, taking care that a covering of some kind is at hand in case of severe frost. By lifting some of the plants carefully when the curds are about the size of a hen's egg the supply of Broccoli may be kept up for some time after the ordinary crop is over. Be careful to lift the plants with a good ball of soil. Clean mats will be found a suitable protection against frost. Cabbages planted four or five weeks ago have been given a dressing of soot and the soil stirred.

Runner Beans.—The supply of these is practically exhausted. Any young pods that are left upon the plants and are fit for use will be picked and preserved by placing the ends in a little water. Pods that have been saved for seed are laid out on mats in a vinery to dry.

F. W. GALLOP.

SCOTLAND.

Stove.—Unsettled weather may, as a rule, be expected about this time, and when it is impossible to further the work out-of-doors advantage may be taken of wet days to clean out and rearrange the stove. The majority of the plants which bloom in this house during late summer and early autumn are now past their best, and as the autumn plants generally and those which will provide a display up till the New Year have made good progress, nothing is gained by delaying to get them into their places. All woodwork, ironwork, and glass ought to be thoroughly scrubbed down with hot water, and in the case of permanent plants in large pots, which are not easily moved, the soil should be removed to the depth of 3 inches and replaced by fresh compost. Such things as Gloxinias, now ripened off, can be shaken out of their pots and stored in boxes among Cocoa-fibre. Many plants can be discarded, such as supernumerary pieces of Eulalias, Panicum, Begonia Rex, Abutilon Savitzi, Tradescantias, and small pots of Coleus, or similar things which can be readily replaced. A feature can now be made of the commoner Orchids, Cyripediums of kinds, *Ceoloyne cristata*, and the like. Late pieces of *Hymenocallis* are always effective, so, too, is a good batch of *Pentas rosea* or of *Justicia carnea*. The winter-flowering *Begonias* may be got into position, and *Libonia floribunda* makes a good display in 5-inch pots. Edging plants may comprise *Ceropegia Woodii*, the finer forms of *Tradescantias*, and *Selaginellas*; *Panicum variegatum* is always useful, and well-furnished plants of *Begonia Rex* in 3-inch

pots will break the monotony of the edging stuff. *Crotons*, *Dracænas*, *Acalyphas*, *Dieffenbachias*, *Sanchezia nobilis* var., *Pandanus Veitchi*, and such like give variety. At the same time climbing plants ought to be considerably reduced in order to admit as much light as possible. Successional batches of stove flowering plants will, of course, be kept in a cooler temperature for some time yet. As regards such things as *Eucharis Lilies*, it is largely a question of heat as to when they may be had in bloom. If they can be plunged in a bed of Cocoa-fibre through which some heat is run, not only will they bloom at an earlier date, but the foliage will be more luxuriant and the flowers of superior quality. Certain hard-wooded plants are yet resting, and until growth begins let them be kept sparingly supplied with moisture. Careful and regular firing is now indispensable. This ought to be in trustworthy hands, for fuel is very expensive, and the utmost value should be extracted from it. A small, clear fire will give quite as much heat as one which is carelessly and wastefully stoked, and will maintain a more regular temperature. In all cases the outside thermometer will prove a safe guide to follow. Night temperature at present, round about 65 degs.

Ferns under glass.—During the summer, Ferns are, in a general way, dispersed among various houses for different purposes. Now, however, they may be assembled in their proper quarters for the winter. Any shabby pieces may be cut over. Young fronds will soon push in a genial, moist atmosphere. In other cases, decayed or ripened fronds ought to be cut cleanly out, the pots scrubbed, and, if necessary, a little top-dressing can be afforded. *Adiantum Farleyense*, *Phlebodium aureum*, some of the *Davallias*, and a few of the *Nephrolepis* family will do better during the winter if room can be found for them in the stove. No shading is now permissible. Occasionally, hosts of seedling Ferns from self-sown spores make their appearance on the surface of the pots. If these are not needed they ought to be promptly suppressed. The commoner forms of *Adiantums* and (especially) of *Pterises* are confirmed offenders in this respect. Only sufficient moisture to maintain good health ought now to be given. Temperature, 58 degs. to 60 degs.

Housing Chrysanthemums.—This important work cannot now be longer delayed; indeed, the earliest varieties ought to have been under cover before this date. The housing of Chrysanthemums means a general overturn in the structure in which the bulk of these plants is grown, and—in the majority of cases, at any rate—there is a tendency to grow rather more plants than can be comfortably accommodated. I started the season with the determination to make a considerable reduction in the numbers grown. As a matter of fact, one way and another, there are actually more than were grown in 1915. Nevertheless, if a little crowded at first, there is soon space made when cutting begins. The plants which occupied the house have had to find other quarters—pits and shelves, in some instances cold-frames having been requisitioned. In housing, all withered foliage is removed before the plants are staged, the stakes are regulated, ties adjusted, and the pots are thoroughly scrubbed. When the house is washed down and staging completed it is advisable for a night or two to run rather a brisk heat through the pipes in order that superfluous moisture may be dried up. At the same time full ventilation ought to be given at the apex of the house. One point is worth drawing attention to: No matter how carefully the bottoms of the pots are inspected when staging is going on, it is almost certain that snails will be introduced. These soon give signs of their presence, and ought to be hunted for, with the aid of a lamp, after dark. This must be done in rather a hurried way in districts such as this, where the lighting regulations are very stringent. On completing the staging, if the house be lightly vaporised on two successive nights, and again in a week's time, it will be found that very little trouble will afterwards be experienced from the attacks of aphides.

W. MCGUFFOG.

Balmie Gardens, Kirkcudbright.

CORRESPONDENCE.

PLANTS AND FLOWERS.

Begonias, keeping (D. G. Buchanan).—Your best plan will be to stand the plants in a frame in order that the growths may dry off, of course, giving no water. When the shoots have all fallen away, you may either shake out the tubers and lay them into dry sand or keep them in the pots. Any spare room or dry cellar into which frost cannot penetrate will do as a store. The boxes must on no account be closely covered up.

Romneya Coulteri buds injured (R. F. H.).—It would seem from the injured buds that you send that earwigs are the cause, and if this is so, then your best plan will be to lay some hollow Bean-stalks among the leaves, and when the pests congregate therein to shake them out into a pail of water on the top of which some paraffin is floating. It may be that caterpillars are responsible for the damage, and a few visits to the plants at dusk may give you a clue.

FRUIT.

Air-roots on Vines (P.).—There is nothing unusual in the Vines producing air-roots; but it is not a good sign, as their presence betokens a want of proper action on the part of the true roots running naturally in the soil, and they are frequently the precursors of shanking. To prevent their formation, or to recover Vines subject to this evil, the border must be seen to, and, if necessary, the Vine roots should be taken up when the crop of fruit is cut, and be replanted in well-drained turfy soil, containing plenty of old mortar rubbish and broken bones.

VEGETABLES.

Celery diseased (H. R.).—Your Celery is badly attacked with the maggot or leaf-miner, and your best remedy, though a tedious one, is hand-picking the affected portions and burning them. You see the maggot is encased inside the skin or leaf-covering, therefore very difficult to get at with insecticide. After removing the worst plants attacked, well dust over with soot, and this will kill the larvæ. By repeated dressings you will at this season soon get a healthy growth, as only the older leaves are attacked, and the new ones, kept free, will soon develop, and strong plants are less liable to attack.

MISCELLANEOUS.

Poor lawn (E. D. Prichard).—Top-dress the lawn with a mixture of loam, rotten manure, and wood-ashes. Let this lie on the surface during the winter, then in the spring break it down fine and brush it into the roots of the Grass. A dressing of sulphate of ammonia or nitrate of soda in the spring, when growth is starting, at the rate of 3 lb. per rod, will do good. If you can get good turf, by all means use this, but if not, then you may sow it down in the coming April, using only the best Grass seed, and not that from a hayloft, which is full of weed seeds, and will cause no end of trouble later on.

SHORT REPLIES.

A. A. Thornton.—The only plants likely to do any good in such a shaded position are hardy Ferns, among which you could plant Narcissi, Blue Bells, Chionodoxas, and other spring-flowering bulbs.—**H. M. W.**—1, Impossible to say why your Celeriac has failed to bulb, as you give us no idea as to how you have treated

it. Only the root is used, as the hollow leaf stalks are so bitter that they are quite unfit for table use. 2, All the Roses you mention should have been dealt with after flowering, cutting out the old and worn-out wood and laying in the vigorous shoots of this year. It is not too late to do this now.

NAMES OF PLANTS AND FRUITS.

Name of plant.—*Rosemary.*—*Leycesteria formosa.*

Names of fruits.—*C. L.*—1, Mère de Ménage; 2, Blenheim Orange; 3, Golden Spire; 4, Golden Noble.—*A. R. Scott.*—Apples: 1, King of the Pippins; 2, Claygate Pearmain; 3, Adam's Pearmain; 4, Court Pendu Plat.—*W. A. S.*—Apples: 1, Red or Winter Hawthornden; 2, Cox's Pomona; 3, Cellini.—*S. M.*—Apples: 1, Ecklinville; 2, Bramley's; 3, Mère de Ménage; 4, Alfriston.—*A. M.*—Apples: 1, Rymer; 2, Yorkshire Greening; 3, French Crab; 4, Wellington.—*S. L. May.*—Pears: 1, Beurré d'Amanlis; 2, Brown Beurré. Apples: 3, Stone's; 4, The Queen.—*W. Wright.*—Pears: 1, Marie Louise; 2, Louise Bonne of Jersey; 3, Beurré Bosc; 4, Beurré Clairgeau.—*N. M.*—Pears: 1, Glon Morceau; 2, Nouvelle Fulvie. Apples: 3, Bess Pool; 4, Cox's Orange Pippin.—*F. G. M.*—Pear: Doyenné du Comice.

Hon. Mrs. Cross.—Apple: Cellini, so far as we are able to say from the single fruit you send us.—*A. B. C.*—1, Cox's Pomona; 2, Tower of Glamis; 3, Mère de Ménage; 4, Claygate Pearmain.—*R. E. 2.*—Apple is, we think, American Mother, a dessert variety in season during October, but it is very hard to say with any certainty from a single fruit. Kindly read our rules as to the naming of fruit.

The Royal Horticultural Society and exemption from rates.—At the Surrey Quarter Sessions (Sir Chas. Walpole, K.B., presiding) the solicitors of the Royal Horticultural Society put forward an office copy of a certificate of the Registrar of Friendly Societies that this society is entitled to claim the benefit of the Scientific Societies Act, 1843, allowing exemption from county, borough, parochial, and other local rates in respect of lands and buildings occupied by scientific or literary societies. The exemption was claimed in respect of the gardens, laboratories, etc., of the Royal Horticultural Society at Wisley. The certificate had to be laid before the Quarter Sessions, who were required by the above Act, without motion, to allow and confirm the same. Sir Chas. Walpole said that the society was entitled to the exemption claimed and the matter was thus disposed of *nem. con.*

LIST OF AWARDS AT THE R.H.S. MEETING ON OCT. 10, 1916.

ORCHID COMMITTEE.

Awards of Merit.

Sophr. Lelio-Cattleya Lutetia, from Messrs. Charlesworth and Co., Haywards Heath; **Odonoglossum perculum**, var. **Nicator**, from Mr. E. J. Mocatta (Gr., Mr. Thomas Stevenson), Woburn Place, Adestone; **Cattleya Venus**, **Orchidhurst var.**, from Messrs. Armstrong and Brown, Tunbridge Wells.

Medals.

SILVER BANKSIAN.—Messrs. Charlesworth and Co.; Messrs. Armstrong and Brown, Tunbridge Wells; Messrs.

Sander and Sons, St. Albans; Messrs. Hassall and Co., Southgate, N.; Messrs. J. and A. McBean, Cooksbridge; Messrs. Stuart Low and Co., Jarvis Brook.

FLORAL COMMITTEE.

Awards of Merit.

Pelargonium General Joffre, from Mr. W. H. Robbins, Leves; **Gemm Borrisi**, from Mr. C. Elliott, Stevenage; **Aster J. S. Baker**, from Messrs. Baker, Codsall; **Nerine Rothschild**, from Messrs. Chapman, Ltd., Rye; **Aster King of the Belgians**, from Hon. Vicary Gibbs (Gr., Mr. E. Beckett), Aldenham House, Elstree, Herts.; **Viburnum dasyanthum**, from Hon. Vicary Gibbs; **Colechium ibyricum superbum**, from Messrs. Barr and Sons, Taplow; **Chrysanthemum Lichfield Pink**, from Mr. J. W. Thorpe, Lichfield; **Dahlia Elaine**, from Mr. J. T. West, Brentwood; **Dahlia Autumn Tints**, from Messrs. Stredwick, St. Leonards; **Dahlia J. A. Jarratt**, from Mr. J. A. Jarratt, Anerley-road, S.E.; **Dahlia Anerley Yellow**, from Mr. J. A. Jarratt.

(All the Dahlias above mentioned also received the First Class Certificate of the National Dahlia Society.)

Medals.

SILVER GILT BANKSIAN.—Mr. J. B. Riding, Chingford, for Dahlias.

SILVER FLORA.—Messrs. Cheal and Sons, Crawley, for clipped trees and shrubs; Messrs. Piper, Bayswater, for Chinese shrubs; Mr. J. J. Kettle, Corfe Mullen, Wimborne, for Violets; Mr. L. R. Russell, Richmond, for Tree Ivies.

SILVER BANKSIAN. Messrs. Allwood Bros., Haywards Heath, for Carnations; Messrs. Bakers, Ltd., Codsall, for hardy flowers; Messrs. W. Cutbush and Son, Highgate, for hardy flowers; Mr. Elisha Hicks, Twyford, for Roses; Messrs. H. B. May and Son, Edmonton, for Ferns, etc.; Mr. G. Reuthe, Keaton, Kent, for hardy plants; Mr. Geo. Prince, Longworth, for Roses; Messrs. Waterer, Son, and Crisp, Twyford, for Asters, etc.; Mr. W. Wells, Junr., Merstham, for hardy flowers.

BRONZE FLORA.—Rev. J. H. Pemberton, Romford, for Roses.

FRUIT COMMITTEE.

Medals.

SILVER HOGG.—Mr. C. A. Cahn (Gr., Mr. T. Pateman), The Node, Welwyn, Herts, for collection of fruit.

SILVER KNIGHTIAN.—The Barnham Nurseries, Barnham Junction, for collection of Apples.

SILVER BANKSIAN.—Mr. J. Chivers, Wychfield, Cambridge, for collection of fruit.

NOTES OF THE WEEK.

Aster St. Egwin.—This is still one of the best, with its large pink flowers, which show to best advantage in artificial light. Of neat habit of growth, it is not nearly so tall as most of the *Novi Belgii* section, averaging from 2 feet to 3 feet, and, if grown from a single crown, will make a compact rounded bush covered with flowers.—N. L.

The blue Hound's-tongue (*Cynoglossum amabile*).—This, to me new and excellent annual flower, is a late bloomer and is pretty in the house in October arranged with yellow or white Roses, or by itself. Easily raised from seed in spring, it is to be hoped it is one of the annuals that endure our winter and that may be sown in autumn. It is almost as good a plant as the blue Cornflower. The colour is a beautiful blue.—W.

Escallonia macrantha.—This deserves all that has been said for it on page 501. I know some parts of Scotland, particularly in the south-west, where it makes quite a good hedge and does not require a wall. In specially hard winters I have known it badly cut, but the recuperative powers spoken of in your note enable this *Escallonia* to resume its former beauty in a year or two. Nowhere have I seen it finer than in the south of Ireland. *E. philippiana*, I find, is the hardiest of the lot.—S. A.

Elsholzia Stauntoni.—This interesting and distinct sub-shrubby plant has been exhibited on more than one occasion lately, and on October 10th was seen in good condition at the Royal Horticultural Society's fortnightly meeting. The plants shown were less than 2 feet high and yet were producing somewhat freely their Veronica-like spikes of pale pink flowers. The serrated leaves are each 3 inches to 4 inches long, very finely pointed, and, when rubbed, not unpleasantly fragrant.

Erigeron strigosus.—I have been delighted with this new annual, which I tried this year, being attracted by the description of it in a seed list. It bloomed all the summer and was a mass of flower the first week in October. Even now (October 18th) it is covered with bloom. It is of rather shrubby habit, with grey leaves and pinky-mauve flowers, with deeper pink buds, and grows about 18 inches high. I sowed it in a cold frame, and put it out in the borders in May in patches of six or eight, and the effect of the cloudy masses of grey and pink was delightful.—E. G. H., *Huxham Rectory*.

Arbutus Unedo in fruit.—I have not noticed whether it is the case elsewhere, but a large, old *Arbutus*-tree in my London garden is fuller of fruit this year than I have ever seen it, the branches hanging down with the weight of fruit, although at present they are only green and not nearly their full size. When they are fully developed the tree will be a lovely sight.—W. O.

Geum Borisi.—This shapely and good form, which attains to about a foot or so high, is among the most brilliant the genus contains, and, by reason of its dwarfness, should be welcomed by rock gardeners generally. The plant is, I believe, of hybrid origin, the well-rounded flowers suggestive of *G. Heldreichi superbum* influence, in some measure at least. The brilliant orange-scarlet flowers are single. It gained an Award of Merit on October 10th last, when shown by Mr. Clarence Elliott, and if a consistent bloomer at that season, or even giving a share of its richly-coloured flowers, the newcomer will be welcome.

Apples in Kirkcudbrightshire.—In a general way the crop of Apples has been poor in the Stewartry. Some growers blame the inclement weather which prevailed when the trees were in bloom, while by others the blame is attributed to a late and severe frost. Be the cause what it may, the fact remains that, all over, the Apple crop is the poorest for a considerable number of years. It is, therefore, the more gratifying to record at least one instance in which the yield has, even in such an untoward season, surpassed the average. At Lauriston, in the garden of Captain Cassady, Bessy's Croft, an excellent crop has been secured all over. Especially is this the case upon a tree of Ecklinville—of considerable age—which bore such a weight of fruit that the branches had to be supported, and from which Apples were gathered by the bushel. The garden at Bessy's Croft is not particularly well sheltered, but the Apples there seem to have missed both the winds and frosts experienced elsewhere. In the case of the tree of Ecklinville it appears that it had practically failed in 1915, although the other trees were heavily laden. Probably the reserve of vigour stored up last year may have stooed the tree in good stead, but, whatever the reason, the crop was phenomenal.—KIRK.

Gentiana sino-ornata.—This is the authenticated name of a brilliantly-flowered species which, when exhibited by Mr. Clarence Elliott at the late September meeting of the Royal Horticultural Society

as *G. ornata* variety, unanimously gained an Award of Merit. A reputedly good doer, this was clear from a solitary-established example in a pan carrying from fifteen to a score of buds and blossoms, while a greater vigour was apparent than is customary with other forms of this welcome and somewhat variable species. Blue-flowered alpine are acceptable at any time. In September and October we are more grateful for them, perhaps, than at other times, because of the scarcity of good alpine with flowers of any colour. Larger flowers with broader, more reflexing corolla lobes than are usual in the species, on first opening they approximate to a good *Gentianella*-blue, which pales later into one of those indescribable blues of which no garden ever has enough. The flowers are solitary, ascending at the ends of decumbent stems, the lighter-coloured tube but enhancing the richer predominating blue. Each flower lasts a week or ten days, hence a succession may give beauty for twice that period. Under cultivation all these prefer a cool, rather moist position in loam, leaf-mould, and peat in about equal parts.—E. H. JENKINS.

The Banksian Roses in Scotland.—It is often said that the Banksian Roses will not bloom in Scotland. This is an error. In certain districts and seasons the Banksian Roses are badly cut by frost and have to be allowed to make fresh growth, which, again, must be thoroughly ripened to induce flowering. I know of one garden where for a number of years the white and yellow Banksian Roses flowered freely every year on a wall. One hard winter these were cut back to near the ground, with the result that it was some three years before they again bloomed. Banksian Roses require at least three years' growth to induce them to flower really well. This means that pruning should be practised very carefully, and in Scottish gardens I know the Banksian Roses require only a few of the shoots which have bloomed to be cut out with some late soft growths. This should be done about July. A warm wall and a sunny position are also essential. Given these conditions success with the Banksian Roses is practically assured in the milder parts of Scotland, but they are not recommended for the colder districts or those where sunshine is much obscured by mists in summer. A wall covered with the white or yellow Banksian Roses is a sight worth going miles to see. Time, patience, and a little consideration would secure this in many a warm Scottish garden.—SUB ROSA.

Lobelia Tupa.—Attention was directed to *Lobelia Cavanillesii* in the issue of September 9th, p. 448, as a brilliant autumn flower not usually met with, and I think the above, a handsome, tall-growing kind from Chili, also deserves attention. Neither may be quite hardy in all localities, though a similar remark may apply to *L. fulgens* and some of its forms. Plants of such well-marked character merit special treatment, even though that occasionally involves slight winter protection to ensure safety. Said to attain 6 feet or 8 feet high, *L. Tupa* commands attention when in bloom by the pyramids of crimson flowers set in downy, maroon-coloured calyces borne on inch-long foot-stalks of like colour. The thick, downy, velvety-inclined leaves on the reddish stems and often exceeding 2 inches in width and 6 inches in length, prove that these are consistent with fine stature; indeed, seen in its best form it is one of the most imposing of its race. Flowering in September and October, very effective when freely grouped, revelling in rich, moist soils and genial atmospheric conditions, it is a valuable plant in favourable localities, or to be indulged in experimentally by those in search of something removed from the stereotyped or commonplace.—E. H. JENKINS.

Gentiana verna.—Will you kindly allow of yet a few more words on the cultivation of *Gentiana verna*, admittedly so difficult and capricious in our gardens? It is obviously one of a class requiring a close imitation of its natural conditions. Given a free, light soil, with lime in some form, moisture, and full exposure to the sun, there, nevertheless, remains yet another condition of success. We recognise that some plants require close association with others in order to grow well. So essential would this seem to be in the case of *Gentiana verna* that some horticulturists have not hesitated to speak of it as semi-parasitic in its habit, a tendency which scientists call symbiosis. Perhaps the French term "commensal" might be accurately applied to its system of growth. The spring Gentian grows in association with Grass, the roots of the two plants freely intermingling. In our lowland conditions Grass grows too luxuriantly, and in time would crowd the Gentian out of existence. Who will report upon its habitat and tell us of another plant in partnership with which the Spring Gentian will be content to live? Possibly *Globularia nana* might be a sufficiently gentle fellow-guest, for even the dwarfest Grasses have, under cultivation, a way of waxing fat and kicking which the Spring Gentian would resent.—T. A. HYDE, *Avon Grove, Avonwick, S. Devon.*

Lychnis Arkwrighti.—I think it was at Holland House Show last year—it may be longer—that I first came across the above name attached to a group of plants in flower claiming to be of recent hybrid origin. The parentage was stated to be, if I remember aright, *L. chaledonica* × *L. Haageana*. The group of plants, however, obviously represented nothing more than the well-known *L. Haageana*, itself of hybrid origin (or seedling variations), first derived from the Siberian *L. fulgens*. The above name has since found its way into some catalogues, and seedlings raised as such are already a source of disappointment. I am reminded of the circumstance by an amateur recently seeking my opinion on the point. He had purchased seed as *L. Arkwrighti*—a supposed novelty—only to find, on its flowering, that he had under this name added to his stock of *L. Haageana*, which he had known and grown for many years. Disappointments of such a nature cause amateurs to be ex-

ceedingly sceptical of much-advertised so-called novelties, while doing not a little harm to hardy plant progress generally. The best strains of *Lychnis Haageana* afford great variety in pink, salmon, scarlet, and crimson, and, in their way, are not surpassed. The whites are dirty-looking and not wanted, even if pure in colour, since there is no scarcity of white garden flowers when the others are at their best. The great enemy of *Lychnis Haageana* is the slug, which in winter devours its crown-buds and, on occasion, its tuberous-inclined roots. In good condition when established in rich, light soil, some of the more brilliant forms will grow 3 feet high.—E. H. JENKINS.

Viburnum Davidi.—The members of the Guelder Rose family are remarkable for a diversity of habit and leaf-development not common among shrubs. Among them *V. Carlesi* is probably unique for its clusters of fragrant white flowers, albeit the plant is of somewhat straggling habit. *V. plicatum*, *V. p. tomentosum*, and others near are equally unique, and on the lawn in bold groups in May or June, when in the heyday of their beauty, they are effective at a long distance. The evergreen *V. rhytidophyllum*, apart from a leaf growth and vigour distinct from all, is effective in autumn when in fruit. *V. Davidi*, also evergreen, is very dwarf and cushion-like in habit of growth. So dwarf and sturdy is it, that it is the only one known to me suited to rock gardening. In such, in a well-chosen position, the hard-looking, handsome, ovate leaves would be attractive at any season, its slowness of growth a guarantee of suitability. The flowers are white, succeeded by small oval fruits of a blue colour. It is, however, for its fine foliage effect rather than for its fruit or flower beauty that I would recommend it.—E. H. JENKINS.

Rhus Toxicodendron poisoning.—Mr. L. P. Shadbolt, F.R.C.S. (Bushey), writes:—

"I have had under my notice during the past month three cases of poisoning by the American Poison Vine or Ivy (*Rhus Toxicodendron*) which have led to the discovery of four very sturdy specimens of this objectionable creeper growing on two houses in this neighbourhood. Last month a patient came to me for advice for a peculiar bulbous eruption on his hands and wrists which was accompanied by intense erythema. Erythema was also present about his face and various parts of his body, notably the genitals. His work was that of a painter. On inquiry, I found that he had been engaged in painting a house in this neighbourhood, and had to clear away certain creepers from the framework of the windows; further, that his 'mate' was suffering in the same way and had been engaged on the same job; also that the gardener at the house in question periodically suffered from the same affection. I went to the suspected house and there found, growing on its walls and reaching to the eaves, two luxuriant plants of the Poison Vine, easily identified by the long stalk of its central leaflet. Further search revealed another specimen growing on a fence in the garden, and on the neighbouring house yet another."

[This plant shows a vicious practice in renaming a well-known poisonous plant as *Ampelopsis Hoggi*, leading some to plant it as a novelty. It retains its virus in England, and should never be in a garden or among climbers. It had also been in gardens under its true name years before.—Ed.]

FRUIT.

STORING APPLES.

THREE things are necessary if one is to keep Apples in good condition for a long time. They must be in the right condition when picked. They must be protected from too much drying. They must be protected from attacks of fungi (rots and molds).

TIME TO PICK.—An Apple is ready to be picked when it is fully mature, but before it is "dead ripe." It should be free from extensive bruises and from diseases. Small bruises where the skin is not broken will dry over and cause no trouble in most cases, but in some varieties (the Northern Spy is a conspicuous example) which have a very juicy, tender flesh and a tender skin, the slightest bruise is likely to allow the rot fungi to enter. In New York State the two most serious Apple diseases are "scab" and "Baldwin spot" or "shot-hole fungus." The latter appears usually on overgrown specimens of many of our Winter Apples, especially where they have grown in the shade on the lower side of the limbs, and in our orchards it sometimes seems to be, perhaps, associated with slight aphid injury. This may be accidental, and simply owing to the fact that the large, tender, juicy specimens grow in the same sheltered situations where there is much moisture in the air as are favourable to the life of plant lice. This injury has the appearance of small depressed patches about an eighth of an inch in diameter with a small brown spot under the skin. They much resemble bruises caused by hail except that they are smaller and usually more numerous. In storage the brown area extends through the flesh of the Apple to the core and appears as bitter brown streaks about as large as the lead of a pencil. The Apple scab first appears on the Apple as a small greyish raised spot in the thin waxy outer skin or epidermis. When this gets about an eighth of an inch in diameter the epidermis begins to break and roll back, and the trouble appears as a black spot. When this gets about one-quarter inch in diameter the centre usually begins to heal up and we have the condition sometimes called "fish eyes." In some varieties, notably Ben Davis and Gano, the healing may be complete and the scar appear as a golden wart, which is one of the usual marks of these varieties. In storage, scab spots which have not developed enough to show when the Apples were picked may grow and injure the appearance of the fruit greatly. The scab fungus itself does not injure the Apple for use, but it gives a chance for various rot fungi to get through the epidermis and destroy the fruit.

Apples stored in a dry cellar without very good protection are almost sure to dry out so much as to be too withered to be very good to eat. The air around each Apple should be as nearly saturated with moisture all the time as possible. Pits and ordinary methods of storage in barrels meet these conditions well, but have other objections. Apples stored in bulk in pits in contact with the earth are likely to lose flavour and become "earthy." Storage in pits and in ordinary barrel methods does not protect the perfect Apples from fungi.

The tough, waxy epidermis of an Apple is a good protection against most of the rot fungi, but if a sound Apple lies against a rotten one sooner or later the fungus will be able to grow through the protection of the good one and destroy it. Wrapping each Apple in paper as it is

placed in the barrel is a great help in keeping the Apples from decay. If

COLD STORAGE is available it is a great help in keeping Apples sound. The temperature should be as low as it can be kept without freezing the Apples. A few degrees below the freezing point of water are usual. This is, of course, the temperature of the air in the room, and the centre of the barrel is always warmer. For this reason Apples can seldom be kept in cold storage more than a few months.—*Rural New Yorker.*

PLANTS AND FLOWERS.

OUTDOOR PLANTS.

A ROSY CLEMATIS.

Rosy Clematises are not common. I grow a good many myself, but not many

very hot and dry summer these Fuchsias are not seen at their best, for, the original species being natives of the Andean region of South America, where moisture-laden fogs prevail, the progeny delights in a good deal of atmospheric moisture. Their partiality for seaside districts is thus accounted for. During the past summer they have been seen to considerable advantage, especially during the comparatively cold, dripping weather that played such havoc with the Pelargoniums. In selecting varieties of Fuchsias for the open air those with small or medium-sized flowers should be chosen in preference to those with large, heavy blooms.—*W. T.*

PLANT VAGARIES.

[*To the Editor of GARDENING ILLUSTRATED.*]

SIR,—Many instructive notes have appeared from time to time in GARDENING

stood still. After three years I lifted it, divided it, and replanted it just on the edge of a pond facing full south, with a rock behind it. It remained there two years, repeating the first phase. I moved it again a distance of, perhaps, 3 feet a year ago, replanting it as near the water as before, after again dividing it, but this time with a lump of rock in front of it. It has never been out of bloom all summer, and there are sprays still showing their lovely colour.

DAPHNE CNEORUM.—In the cultivation of this plant it is generally said peat, or loam, or leaf-mould, or all three are necessary. I had a bank composed of newly-dug clay with a very little top soil. Farmyard manure was incorporated with it, and later, to keep the soil open, a heavy dressing of lime was dug in. On this bank-side, amongst other things, two plants of *Daphne Cneorum* were put in about ten or twelve years ago. They grew with a will from the first. One of them is now roughly oval in shape and measures 7 feet by 4 feet, and every spring the flowers hide the leaves. The other had to be moved to another position on the same bank, which checked the growth, and it only measures 3½ feet by 2½ feet. I planted another in sandy peat and loam. It promptly died.

PAMPAS GRASS.—This is generally said to require rich, light, sandy soil. I have four or five big clumps. One is at the north end of the rock garden in strong loam, into which the roots of trees and shrubs penetrate. It does well. Another is planted at the back of the rock garden in very light, gritty soil, facing full south. It does less well. Another is planted in strong, clayey loam on a bank much exposed, and is an immense clump full of plumes. Another is within a few inches of the edge of the pond in very strong, clayey soil. Its roots are always in the water. It does best of all, and is now carrying forty or fifty plumes each over 7 feet in height. Last year it had over sixty plumes on it.

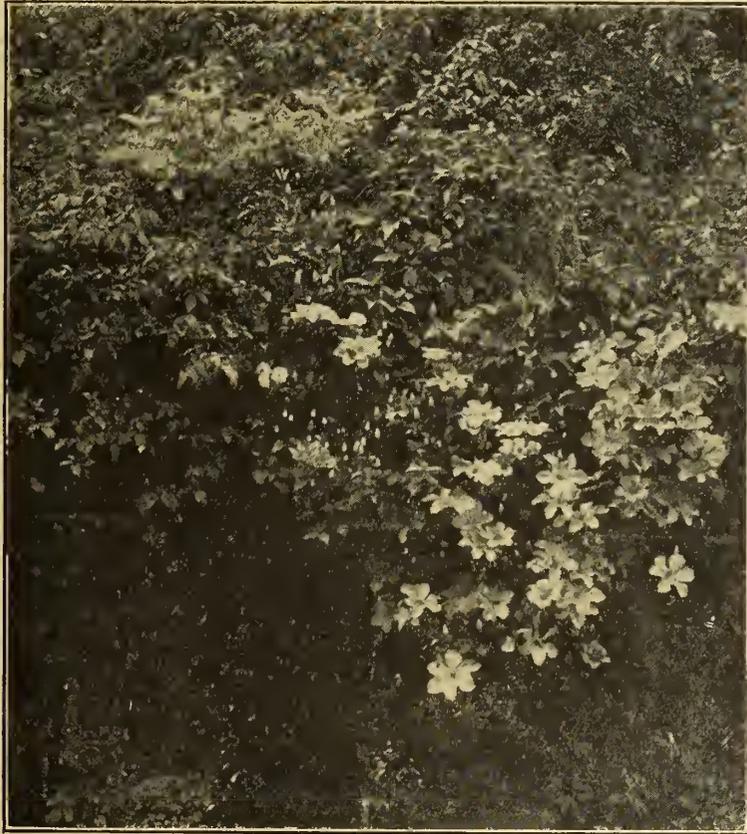

YUCCA FILAMENTOSA.—This is said to require sunny banks and light, well-drained soil. I have one planted in a good position on the rock garden in full sun. It is now in bloom, but has no special vigour. Another was planted at the same time by the water-side in the shade of the Pampas Grass in a pocket of good loam. It grew well and flowered well, but a water-rat ate the flower-stalk and the stump of the plant completely down to the ground two years ago, and I bid goodbye to it. Last year it threw up a number of shoots round about and at some distance from the old stem. These have now grown into strong, healthy-looking plants, but have not yet flowered. The roots are always in water.

PRIMULA JAPONICA.—This is a bog plant, and, it is said, should always have its toes in the water. I have a group in such a position and they flourish. I have an older plant amongst grit and stones on a raised part of the north side of the rock garden. The only moisture it gets is that conserved by the stones. It flowers equally well and is the seed-parent of hundreds of plants growing all over the garden, but it is less gross in growth.

SNOWDROPS were a weed with me fifteen years ago in my garden a quarter of a mile from my present residence. I cannot establish them in my new garden.

MONTBRETIAS.—My present "weeds" are Montbretias, which receive no care or protection, but bloom and spread as persistently as Buttercups.

I might go on enumerating a score of instances, all of which would lead to the same conclusion, viz., that whilst there is

Rosy Clematis on rustic arbour at Warley Place, Great Warley, Essex.

of the character of this. Here is an illustration of one in Miss Willmott's garden as a seedling. It well deserves to be better known. It looks as vigorous as a Clematis should. *W.*

Fuchsias in the flower garden.—In many places old plants of greenhouse varieties of *Fuchsia* are used in the flower garden during the summer. They are mostly kept for this purpose year after year. Their old and gnarled branches when they are devoid of leaves do not, at least to the uninitiated, promise much of a future floral display. With the return of spring, however, if the loose shoots are shortened back and the plants placed under conditions favourable to growth they soon become a mass of young and tender shoots, while a profusion of flowers will make its appearance in due course. These old plants flower more freely than the young and succulent ones. Given a

ILLUSTRATED as to the special requirements of different plants. It is probable that there are an ideal situation, treatment, and soil, but as these are generally unattainable and frequently unknown we are apt to lay too much stress upon securing them. Plants, like human beings, have their likes and dislikes, but equally so many of them can thrive and multiply under quite opposite conditions, and I like to think of them as possessing individuality and able either to rise superior to their environment or to petulantly strike for better conditions. These thoughts arise from a perusal of the contrary advice often given by experts, all of whom I have no doubt write from personal experience. Let me give one or two facts from my own experience.

OURISIA COCCINEA.—I planted a clump in a cool, damp part on the north face of my rock garden. It lived; never flowered;

in the plant world a number of irreconcilables demanding special treatment, the great majority are adaptables and will make the best of what is given to them, and also that some plants seem to have a double dose of original sin and are intractable, whilst others are so amiable that, Mark Tapley like, they will flourish in spite of the most adverse conditions.

NORTH YORKS.

AMONG THE HARDY FLOWERS.

COVERING LATE BULBS IN FLOWER.—It always makes me sad to see the bulbs which are in flower in autumn suffering from the bad weather that then very often prevails. I have found it worth while to have some protection at hand to keep rain off the blooms. Hand-lights, bell-glasses, cloches, etc., are expensive, but I find a piece of flat board useful if supported above the flowers by means of sticks and with a stone on the top to keep the board from blowing off. By this simple means I have prolonged the beauty of many flowers for quite a considerable time.

TOAD-FLAXES.—I should be glad to get rid of *Linaria repens* from my rock gar-

den. Once it gets hold it creeps under stones and comes up in the middle of some other and, perhaps, choice plant, and it is almost hopeless to attempt to get it out without injuring a more highly-prized specimen. This creeping habit of the Toad-flaxes, present in nearly all that I know, detracts a great deal from their value, unless one has some spare corner or wild place for them. *Linaria Cymbalaria* is a troublesome plant as well. There is one called *æquitriloba*, which creeps over and among other plants in a most insidious way. It is rather a nice little plant with small leaves and tiny flowers, but it wants careful supervision or it will become a perfect old man of the sea. The best of the family, to my mind, is *Linaria alpina*, whose only fault is that in a severe winter it is liable to perish.

MONTBRETIAS.—This has been a good season for the Montbretias, and I have learned the importance of lifting and replanting the corms when at rest if I want to get the best spikes and flowers. When they are left too long the clumps become crowded. By lifting them and planting the larger-sized corms by themselves a little apart much better flowers are ob-

tained. If increase is wanted the small corms may be planted by themselves in a nursery-bed to grow on.

HELIENIUM AUTUMNALE STRIATUM.—A friend gave me a bit of this, which he said he had got under the name of *Helenium grandicephalum striatum*, but that the above was the correct one. I am content, when speaking of it, to call it simply *Helenium striatum*. It is a good autumn-flowering plant, growing to 3 feet or 4 feet high. The blooms vary in their colouring. Some are almost pure yellow, flushed with a little brown or red, but others are more conspicuously marked in stripes with these colours. Others, again, are almost wholly chocolate or warm red, and come nearer to the newer Riverton Beauty.

AN AMATEUR OF HARDY FLOWERS.

MICHAUXIA CAMPANULOIDES.

This is one of the most remarkable plants of the Bellflower order. Eminently well-fitted to free grouping when so grown, it is capable of creating a feature of rare interest and beauty in any garden, a solitary example or even a few giving but little idea of its worth. Meagre-habited

ordinary border. Far better that it be planted in generous groups near shrubs of sombre leafage. Flowering period, July-August. Warm, well-drained soils and sheltered places are to its liking. Seeds are very cheap, and there is no reason why in large gardens it should not be planted freely. Well grown, it may reach to 5 feet or 8 feet high. The flowers are white, tinged purple on the outside, and, appearing from the leaf-axils, are disposed candelabra-like in the upper parts of the plant. Native of the Levant about Aleppo and on Mount Lebanon, it has been known to cultivators nearly 130 years. A goodly group is seen in the accompanying illustration, and, to ensure such displays, seeds should be sown annually.

E. H. JENKINS.

Mr. Chas. Oakford, Mells Park Gardens, Frome, who sent us the photograph from which the illustration was prepared, sends us the following note as to his mode of culture:—

"The *Michauxia* has been much admired here this summer, there not having been much rain to spoil the flowers. I sowed the seed in early spring in a warm house and plant out the seedlings where to flower in April. They make fine, large clumps and stand the winter well in light soil, and flower the following summer. I have had the plants throw side growths and flower the next year, but I prefer to sow every spring."

HARDY FUCHSIAS.

Those who may be seeking for variety in the outdoor garden should try some of the many varieties of *Fuchsia* which succeed well in the open ground and can be relied on to become well established and increase in blooming power from year to year. Such kinds as *Riccartoni* and *globosa* have long been inmates of cottagers' gardens, but there are others equally suitable which have probably been forgotten. *F. gracilis* is very old and very hardy, and old specimens may be found here and there in cottage gardens. *F. macrostemma* is robust and one of the hardiest, and *F. corallina* is free-growing and effective. The miniature *Tom Thumb* is pretty and suitable for very small gardens, and *Dunrobin Bedder* and *Enfant Prodigue* are very ornamental. The gem of the family is undoubtedly *F. Carmen*, which has large, highly-coloured blossoms on a stem which, under the best culture, does not exceed 1 foot and is frequently not more than 6 inches high. That very old greenhouse variety, *Venus Victrix*, which in the earliest days of *Fuchsias* was regarded as a little wonder, does well in the open ground. *Mme. Cornelson*, with white and red flowers, never, I think, grown under glass nowadays, is very showy, and that good old kind, *Rose of Castile*, forms a perfect mass of bloom. I have had these in the open ground for seven or eight years. Sometimes the crowns had the protection of a little leaf-soil, and in late summer and autumn they were a mass of bloom. I have tried some other kinds, such as *Mrs. Marshall*, *Crinoline*, etc., but with partial success only. The question of economical furnishing comes up strongly nowadays, and for beds on the lawn these *Fuchsias* are admirable, and need no annual planting. Some cheap hardy bulbs planted with them would lead the way in the flowering time.

Byfleet.

J. CORNHILL.

subjects are not, as a rule, suited to isolation, but, grouped on a generous scale, their value is apparent. In this, probably, gardeners have not fully appreciated the merits of an exceptional plant. Equally probable, too, is it that its cultural requirements are not understood by all. A biennial for all practical purposes—though in some instances plants may take two or more years before reaching the flowering stage—it is not always accorded at the start those systematic methods of culture—timely seed-sowing and the like—which for plants of a biennial nature are considered essential to success. Where this is so a moderate development only ensues, which does not do the plant justice. Where no artificial heat is at hand seeds should be sown in pans in a frame in autumn or with slight heat quite early in the year. Either of these should result in moderately good plants for planting out in May. If established in pots so much the better, and, with a full season ahead for growth, a representative flowering should follow in the ensuing year.

By reason of its uncertain flowering and tall, spare habit it is not recommended for, or, in my opinion, even suited to, the

Geranium cinereum album.—This beautiful albino form is a most satisfactory plant for the rock garden, as it is of quite easy culture in well-drained gritty soil, never encroaches on

Part of a group of *Michauxia campanuloides*.

its neighbours, and goes on blooming all the summer until quite late in the autumn. Here, at the beginning of October, it is still throwing up plenty of its delicate white flowers, and these, combined with the beautiful foliage, always make a pleasing little picture. I grow it on a retaining wall in a limy soil. It can be easily raised from seed, which it ripens freely. The seedlings usually come true.—N. L.

CROCUS SPECIOSUS.

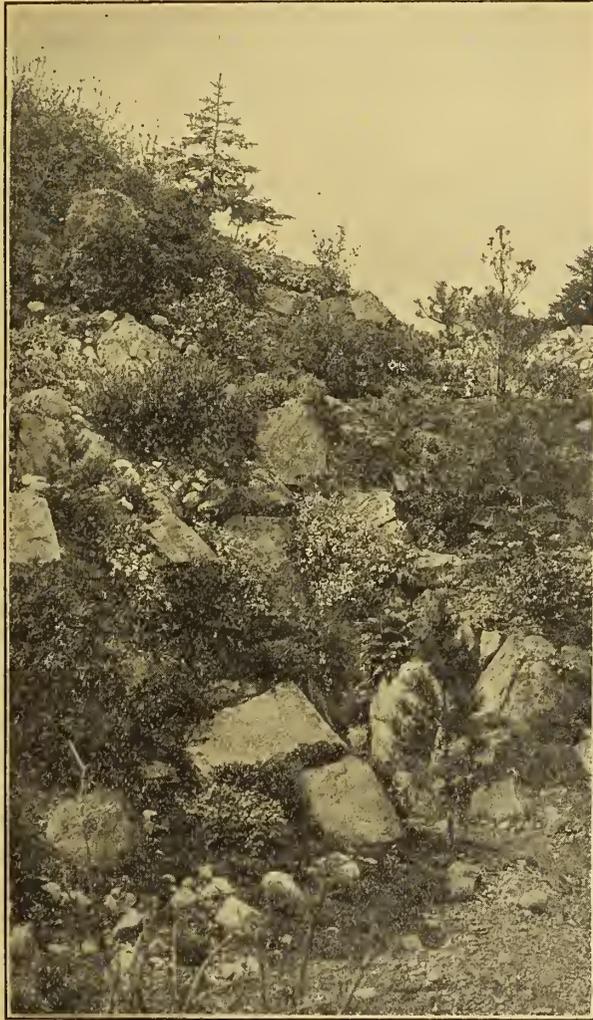

This is more cup-shaped than other Crocuses when fully expanded, and, except in a few well-marked forms with long and narrow segments, seldom opens into a star-shaped flower. The deeper-coloured and bluer forms are the more globular in outline, and the pure white, and some very large forms with outer segments of pale grey tinged with lilac, are the most starry of all. Somewhere and at some time this large form was called variety *Aitchisonii*, but I have never been able to find a description of it or its native locality. The name suggests the most Eastern ranges of the plant's distribution, as most plants named after Aitchison are from the Afghan frontier, and the most Eastern record we have for *Crocus speciosus* is Astrabad, just south of the Caspian Sea. It is a mysterious plant in other ways, and though the first roots I ever had of it, one of Mr. Elwes' kind gifts, seldom flower before the greater number of the darker forms are over, I find seedlings approaching it in colour and equalling it in size now and again among those raised from other forms, and flowering as early as any.

The rich blue of *C. speciosus* gives it its great value in the autumnal flower-beds, for whether rising out of a carpet of fallen leaves of many shades of bronze and orange, or from the bare brown earth, the effect is wonderfully pleasing. Again, as a groundwork under autumn-tinted shrubs, or among brightly-coloured flowers, the drifts of blue are unlike any other effect produced at any season. One of the easiest to grow, and certainly the freest of all Crocuses in its dual method of increase, by seeds and bulbils, it can be allowed to spread about in the borders, and year by year there should be an increase of its colonies. Even digging does not kill them, and they do not mind how deeply they get buried, and after a year or so re-appear as vigorous as ever.—E. A. BOWLES in *Garden*.

Bulb planting.—If any bulb planting yet remains to be done, let it be finished without delay. In planting, a dibber with a blunt end is essential; if a tool with a pointed end be used the bulb does not reach the bottom of the hole, and water is apt to lodge in it beneath the newly-planted bulb. This, naturally, is detrimental to the roots when they begin to push. Should sand be plentiful, a little placed at the base of each bulb will be

found of advantage. There is, as is well known, a shortage of foreign bulbs; but there is a plentiful supply of home-grown material, and at prices which compare favourably with those of foreign origin. Some of the finest *Narcissi* in these grounds came from the Channel Islands a number of years ago; and certainly the finest Darwin Tulips in the garden were bought in Ireland. It ought to be borne in mind that in the woodland—in places where bulbs have been largely naturalised—there is plenty of the commoner varieties of *Narcissi* which may be drawn upon to some extent for forcing, either for the purposes of decoration in pots or for forcing in boxes for cutting.—KIRK.

Michaelmas Daisies.—I do not remember having seen Michaelmas Daisies so freely flowered as they are this year, while the colours of the flowers seem to me to be brighter than

A wild corner in Mrs. Greer's garden at Curragh Grange, Co. Kildare.

usual. The plants will grow in almost any soil, and it is probably owing to this that they do not generally receive the treatment they so well deserve. The outside portion of each old clump always does the best, thus proving the necessity for providing new, fairly rich soil. All ground intended for these plants should be deeply dug, or, better still, trenched.—G. G. B.

Aster Drummondii.—This very late variety is not yet (October 12th) in bloom, but if frosts hold off it may be expected to flower shortly. In seasons when very early frosts are experienced this variety fails to bloom; but even with this drawback, it is worthy of inclusion. Its china-blue flowers, freely produced in sprays, are charming in mid-October; and, in addition, the habit of the plant is quite distinct from that of the generality of *Asters*.—W. McG.

ROCK, ALPINE, BOG, FERN, AND WATER GARDENS.

A WILD CORNER.

The illustration shows a wild corner in Mrs. Greer's alpine garden at Curragh Grange, Co. Kildare. Here alpine plants of all sorts thrive with vigour, as the ground is open and well drained, and the soil is perhaps somewhat better than may be at first assumed by the appearance of all the rough-looking stones.

R. H. BEAMISH.

Stone for rock garden.—Do you know the red Norfolk sandstone? Is it reliable for this work. They build the houses with it near Sandringham, and I can have it fairly reasonable in price. I am also offered blue and brown limestone from Ancaster, both colours in each piece of stone. Can one have all brown limestone and the blue and brown mixed in one stone used for the same garden? They both come out of the same quarry and from one large block. I have been told it would look unnatural.—(Dr.) CECIL A. P. OSBORNE, F.R.C.S.

[We know nothing of the Norfolk sandstone to which you refer, and the "mixed blue and brown," also mentioned, would be simply hideous for the rock garden. The best stones are the weathered limestone and sandstone, these being available in considerable variety in many parts of the country. Their chief value lies in their porosity and their sympathy with plant life. In humid districts or where the rainfall is heavy some of these soon attract lichens and mosses, and, quickly toning down, present quite an old-time look in the space of a year or two. Hard, impervious stone as granite is unsuitable. Cheap stones are often the dearest, and very often are quite unsuitable into the bargain.]

Pentstemon isophyllus, increasing.—I find some difficulty in striking this. Would you use soft wood or not, and would you take the cuttings with a heel? Will "E. H. Jenkins" kindly tell me where I can buy the half pots he writes about in his article on "Cobweb Houseleeks in pots," page 515?—CECIL A. P. OSBORNE.

[There should be no difficulty in rooting cuttings of the right sort, youthful, *i.e.*, soft, cuttings being the best. It is late now to root such in a cold frame, though they would respond to slight warmth. Heels are not desirable and take longer to root than the others. For autumn work a stem or two should have been cut back slightly in July, the resulting growths from which at 3 inches long would furnish cuttings of the right stamp, and, inserted about mid-August, would have been well rooted by this time. If you have greenhouse warmth a plant might be lifted and put into a frame, having been first shortened back. Placed in the greenhouse in February, fresh young growths would soon appear, and which root readily in sandy soil in a closed frame. The half-pots are usually only made to order, and if you require a small number only you would get them best by applying to some of the specialists who grow alpine plants.]

Polygonum affine or Brunonis.—This has been a good year for this Knotweed, and there are still (mid-October) many of the short, crowded spikes of red or pink flowers which overtop the brilliantly-coloured leafage. I grow it on a north-east exposure, which it appears to like. It is easily increased by division, and forms a low trailing or creeping plant only a few inches high.—S. A.

Saxifraga L. C. Godseff.—A capital doer and a really good plant is this Saxifrage. *S. Burseriana* is one of its parents, but it has yellow flowers. It was raised, I understand, at the nursery of Messrs. Bees, and has made its way into gardens by reason of its beauty, its good growth (for a plant of its class), and its free-flowering habit. In March and April it is usually very pretty, its nice yellow flowers

rising above a spiny cushion of grey. It is a grand plant for the moraine or in a dry rockery with lime.—S. A.

Ramondia serbica.—Some like *R. serbica* better than *R. pyrenaica*, while others consider them of equal value. Both may be grown in a shady place, where they will not suffer from drought during the spring, summer, and autumn. They are charming in the crevices of a wall or rock garden facing north. *R. serbica* and *R. pyrenaica* should be planted so that they do not grow on the flat, with their leaves and flowers fully upright.—S. ARNOTT.

CHRYSANTHEMUMS.

PLANTS IN THE FLOWER GARDEN.

EARLY in the season the plants did not make very satisfactory progress. While under glass they grew steadily, but when planted out, the cold weather, especially at night, accompanied by frosts, till about the middle of June, checked growth considerably. At the end of July there was every promise of a rich harvest of blossom. The spell of dry weather in June may in some soils have induced premature flowering of certain varieties. This should be prevented by copious waterings, not only with clear, but also manure, water. The growth will be encouraged, the stems strengthened, and the blooms fresher and of more substance. Furthermore, the plants will be larger, too, and fill up all space in the borders. Some varieties are doing remarkably well, notably *Carrie*, a rich yellow, very dwarf. It is classed as a September-flowering sort, but with me it begins to bloom the second week in July. *Polly* is another dwarf variety, whose rich orange-coloured flowers will soon be open. *Horace Martin* (yellow) and *Crimson Marie Masse* are still valuable sorts. *Normandie* (delicate pink) and *Provence* (pink with golden points and centre of bloom) are two that should be grown by every lover of border Chrysanthemums. Others are *Mme. Marie Masse* (ilac-mauve), *Caledonia* (ivory-white), *Belle Mauve* (mauve), *Almirante* (chestnut-crimson), *Gertie* (salmon-pink), and *La Garronne* (terra-cotta).

VARIETIES FOR CUT BLOOMS.—The following are very beautiful and serviceable for cutting in September, October, and early in November. They can be grown and flowered, without the aid of glass, throughout, and are of great use to amateur cultivators who do not possess glass structures. *Roi des Blancs* (pure white), *White Quintus*, *Le Pactole* (bronz-yellow), *Mrs. Roots* (pure white), *Ethel Blades* (chestnut-scarlet), *Source d'Or* (bright orange), *Lizzie Adcock* (yellow), and *October Gold* are only a few of many good sorts, but they are doing very well this year.

The great points in the management of the plants are watering and feeding, not with a view to the forcing of the growth, but to strengthen it so as to obtain the best blooms possible at a minimum of expense and labour. Many plants may be lifted and potted with good results by amateurs and others with very little experience. The time to lift is when the buds have just formed. G. G. B.

Chrysanthemum Mons. W. Holmes.—A good November-blooming Chrysanthemum, now almost forgotten, may be found in the above-named variety. The colour may be described as a rich, dark terra-cotta, turning lighter at the edges of the petals. If planted in the open during the summer, and lifted on the approach of frost, fine pieces may be obtained with the minimum of trouble, and which will give a large amount of material for cutting. Some of these old Chrysanthemums are much more valuable for general purposes than those of more recent introduction.—KIRK.

GARDEN FOOD.

CELERY COOKERY.

APART from its use uncooked and in salad, Celery is precious for winter use in the hands of good cooks. The Turnip-rooted form, hitherto much neglected in our country, is a good winter vegetable, more easily grown than the blanched Celery, and an aid in winter when vegetables are scarce. As a salad, Celery should be more thought of, sometimes using it with other salads, like *Lamb's Lettuce*, which in many gardens is in good use now.

BAKED CELERY.—Parboil and drain eight heads of Celery. Finish cooking in white stock. Season very lightly. Drain, strain, and skim the cooking liquid and thicken with a tablespoonful each of butter and flour cooked together. Take the sauce from the fire and add the yolks of three eggs and half a cupful of grated Swiss cheese. Put the Celery into a buttered dish, cover with the sauce, sprinkle with crumbs and cheese, and bake for ten minutes in a brisk oven.

STEWED CELERY.—Cut cleaned Celery stalks into 3-inch lengths and cook until tender in stock to cover, seasoning lightly with salt, minced Parsley, and grated Onion. Drain, strain the liquid, and thicken with flour browned in butter. Re-heat the Celery in the sauce, and serve.

CELERY IN BROWN SAUCE.—Clean and trim three heads of Celery and cut into 4-inch lengths. Cover with boiling water, let stand for ten minutes, drain, and rinse in cold water. Tie in bundles and put into a saucepan with three cupfuls of hot stock. Add one-fourth cupful of butter or dripping, half a Carrot, half an Onion, a little salt. Cover and simmer until tender. Drain the Celery, strain the liquid, skim off the fat, and thicken a cupful or more of the cooking liquid with flour browned in butter.

APPLE AND CELERY SALAD.—Two or three crisp, juicy Apples, one head Celery, salad dressing, and a little Lettuce. Use the inner portion of the Celery. Wash it, cut it into fine shreds, and let it lie in cold water for half an hour. Then drain and dry it well in a cloth. Peel, core, and with a silver knife cut the Apples into very thin slices. Put the Celery and Apples into a basin, pour over enough salad dressing to moisten them, and mix together very lightly. Line dish with a few fresh salad leaves.

SAVOURY CELERY AND MACARONI.—Take three heads of Celery, milk, and water, Bay-leaf, 2 oz. macaroni, $\frac{1}{2}$ pint white sauce, white pepper, nutmeg, salt. Trim and wash the Celery, boil till tender in the milk and water, seasoned with salt and Bay-leaf. Drain the Celery, and cut into 2-inch lengths. Cook likewise macaroni in salted water, and when done drain on a sieve and cut into short pieces. Heat up the white sauce, put in the Celery and macaroni, season to taste with pepper and a grate of nutmeg, and let the whole simmer gently for about fifteen minutes or longer. Care must be taken not to mash up the Celery or macaroni. Dish up on a hot dish, and serve.

CELERY SOUP.—Trim and wash two heads of Celery and cut into small pieces and boil in salt water or stock for thirty or forty minutes. Boil a blade of Mace and a small peeled Onion in one pint of milk. Mix an ounce of flour with a little cream or cold milk. Add this to the boiling milk and cook for ten minutes. Now add this to the cooked Celery, and season with pepper and salt. Then put all through a fine sieve, reheat the soup, add a little cream, and serve with some fried croûtons.

BRAISED CELERY.—Trim and wash six heads of Celery and cut them into 3-inch or 4-inch lengths. Tie up, blanch them in salted water for five minutes, and drain. Next place the Celery in a stewpan, a sliced Onion and a small bouquet garni—i.e., Parsley, Thyme, Bay-leaf, and Marjoram. Moisten with stock, cover and braise slowly in the oven for about thirty-five minutes to forty minutes. About ten minutes before serving add a gill of rich brown sauce. Take up the Celery carefully and dish up. Strain the sauce, boil up and then pour over the Celery. Serve hot.

NOTES AND REPLIES.

Celeriac.—In these days of want of labour this crop is welcome, as it requires none of the earthing-up necessary for Celery. It is always well worth growing and an aid to the good cook. It is commonly and well used in French kitchens. It grows best in the coolest and best parts of the garden.

In preparing it wash the root well with a vegetable brush, and peel it. Cut in halves and quarters, or in slices an inch thick. Melt a lump of butter in a saucepan; when it frizzles put in as many pieces as the saucepan will hold, letting them lie flat to brown all over. Take the pieces as they are browned on to a plate, until they are all fried; then put back all the pieces, cover close, and stand the saucepan on the stove, where they will not burn, for twenty minutes. Turn them out carefully on a hot vegetable dish, season with salt and pepper and a little finely-chopped Parsley. Another way is to melt a lump of butter in the saucepan with half a teacupful of water, put in the root, cover close until tender—from twenty minutes to half-an-hour if quite fresh, but when a little stale it takes longer. When tender, mix quite smooth with a little cold milk a teaspoonful of flour, dish up the root, pour the thickening into the water and butter, let it boil for five minutes. Season very lightly and add the juice of half a Lemon; pour over the vegetable, and serve. It can be served in brown sauce; also made into fritters, after being first cooked until tender, and served with Parsley sauce, Fennel sauce, soubise sauce, or any sauce you fancy.

CELERICAC AU GRATIN.—Plainly boil and drain, put into a gratin dish and cover with sauce made with two tablespoonfuls of cream or Bechamel sauce. Add two tablespoonfuls of grated cheese, some red pepper and salt, bring to the boil, and cover Celeriac. Sprinkle some breadcrumbs and put small pieces of butter on top, and brown in moderate oven.

CELERICAC IN BATTER.—Dip Celeriac in plain batter made with two tablespoonfuls of flour, a few drops of salad oil, yolk of an egg, and a little water. Mix well together, add the whites of two eggs whipped stiffly, and fry brown. Serve with Tomato or Hollandaise sauce if liked. To Celeriac plainly boiled and drained add egg and breadcrumbs and fry in butter to a light brown. Serve with light Bearnaise sauce.

The Canteloup Melons.—A trial of these for the first time has turned out well, in spite of the cold season and the absence of the gardener at the war. They were planted in cold frames often not in use in summer. The kinds are those grown out of doors about Orleans and Paris in open beds with a start under a cloche. In England, with a slightly cooler climate, we put them into frames and get a fair record in fruit. To some the flavour is more agreeable than that of the English green-fleshed Melon.—W.

Cauliflowers.—I have met with a good many instances of mid-season Cauliflowers doing badly this year, and can confirm what "W. McG." says on this point on page 501. Further east in south Scotland the failure is not universal, but frequent. It is a great disappointment, and probably the unfavourable weather has had a good deal to do with the trouble.—A.

I was very much interested in reading the note on Cauliflowers by "W. McG.," *Balmae*, Kirkcudbright, October 7th, page 501. In Hampshire the same condition of things prevails, some of the early varieties being equally unsatisfactory; I never saw plants grow so slowly. Many plants of the mid-season varieties bore a number of heads instead of one, these in many cases becoming purple before they were half developed. Late sorts are doing much better. Some plants grown in a warm, light soil were quite normal. I think the cold spell of weather was responsible for the failure.—BOURNE VALE.

Apple Bramley's Seedling.—This fine Apple realised 11s. a bushel, equal to more than 3d. lb. wholesale, at Covent Garden on Wednesday, October 18th.

TREES AND SHRUBS.

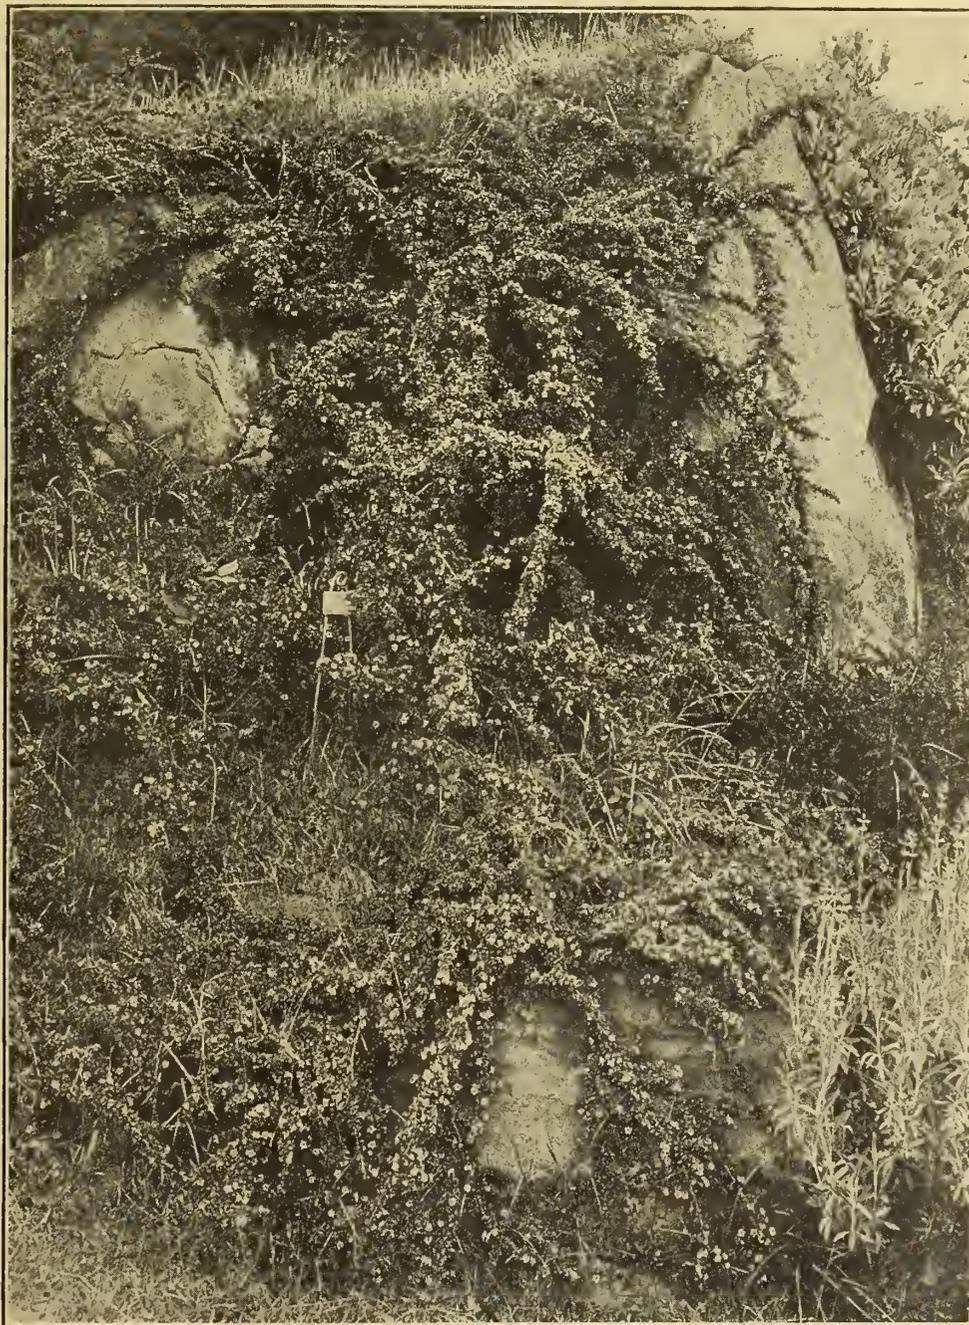

COTONEASTER MICROPHYLLA.

This evergreen Rock-spray has tiny deep green leaves, and in the spring is crowded with whitish blossoms, the berries crimson, and, if untouched, remaining on the plants for a long time. There are some well-marked varieties of *C. microphylla*, one of which—*thymifolia*—is smaller in all its parts, while *congesta* has even more of a procumbent habit. *C. microphylla* is useful for sloping banks or like positions,

grown in British gardens for over 200 years, although it is now by no means common nor well known. It does not grow very tall, and at maturity may be any height between 15 feet and 30 feet, usually forming a wide-spreading, flattened head. The leaves are somewhat like those of the better known *C. orientalis* in appearance, though rather less hairy, and the two species have often been confused. The fruit, however, of *C. Azarolus* is much larger than that of *C. orientalis*, the larger ones being an inch in diameter, usually

THE SUMACHS.

The Sumachs or species of *Rhus* form an attractive group of plants, whilst in their native countries several species are of considerable economic importance. They are widely distributed, for they occur in Europe, Asia, and N. America. Their principal value as ornamental plants lies in their foliage; a few, however, bear showy fruits. They vary a good deal in habit, some forming low bushes, others having more or less scandent branches; whilst others, again, grow into big bushes

Cotoneaster microphylla.

while it will cover a wall with such a dense mass that nothing else can be seen. Again, in the lower parts of the rock garden a place may be found for it, the variety *congesta* being more at home when draping a large stone than in any other way. On the lawn the spreading shoots dispose themselves in a very pretty way when planted as a small group.

The Azarole (*Crataegus Azarolus*).—This is distinct by reason of its large, edible fruits. A native of the Orient, it has been

yellow or orange in colour, but often marked with red on the sunny side, and sweeter than the fruits of *C. tanacetifolia*, which is another Oriental species quite distinct from *C. Azarolus*, both by its more hairy leaves and by the yellow fruits bearing curious green bracts upon the skin. *C. Azarolus* should be given a sunny position in good loamy soil, for in shade it is not likely to fruit freely. Although the fruits are used regularly in some continental countries, they do not appear to be put to any good use here.—W. D.

or moderately-sized trees. Their economic value lies chiefly in their leaves and sap, and in large galls that are formed on the leaves after they have been punctured by a tiny insect. It is from the sap of a *Rhus* that the varnish which is used in the manufacture of the famous Japanese lacquer ware is prepared. The leaves and galls are rich in tannin, and they are used extensively for tanning various kinds of leather. In addition to these uses a waxy substance, which is used for candle-making and for other purposes, is obtained from the fruits

of one or two species. Unfortunately, the sap of two or three species of *Rhus* is poisonous to many, though not to all, and if it comes into contact with the skin an eczema-like eruption follows, which is attended by considerable irritation. Attention is directed in the following notes to the two—*Rhus Toxicodendron* and *R. venenata*—chief offenders, and though both are beautiful shrubs it is wise to banish them from the garden. A few of the Sumachs are not very hardy, but the majority of the ten or twelve species in cultivation can be grown in many parts of the British Isles. They succeed in ordinary garden soil, thriving best, perhaps, in that of a rather light, loamy character. Propagation can be effected by means of seeds or by cuttings or layers, root cuttings in most instances being successful.

R. CANADENSIS is a rather dense but rambling shrub usually 3 feet or 4 feet high, with three-parted leaves and yellow flowers produced from the leafless branches a little in advance of the leaves. The fruits are red, but they are rarely borne in sufficient numbers here to attract attention. In autumn the leaves colour well before they fall, the colours being orange, bronze, and red. The variety *trilobata* is, if anything, more attractive in autumn. The type is from Eastern N. America and the variety from the western side of the same Continent.

R. COTINOIDES is known as Chittam Wood in the South-Eastern United States. It sometimes grows into a tree 30 feet high in its native habitat, and is of interest by reason of its pale green, oval leaves in summer, and by the beautiful colouring of its leaves in autumn, the colours being then very delicate shades of yellow, orange, and scarlet. It appears to give the most satisfactory results on rather poor, firm ground, growth on loose, rich soil being gross and late, whereby the best autumn colouring is not obtained and the branches are too soft to successfully withstand severe frost.

R. COTINUS is a well-known species from Southern Europe, where it is known by the popular names of Venetian Sumach and Smoke Plant. It grows into a bush 8 feet to 12 feet high and as far through. Though smaller, the oval leaves are very similar in outline to those of *R. cotinoides*. They are, however, darker in colour and are often of a decided blue-green shade. The most remarkable feature of the plant is the large, feathery inflorescences. The flowers are very tiny, but after they fall, the thin, thread-like stalks continue to develop until the seeds are ripe, by which time the network of tiny stalks forms a very conspicuous object, particularly in the variety *atropurpurea*. The combination of feathery plumes and blue-green leaves has led to the common name of Smoke Plant. Another common name is "Wig Tree." The leaves of this bush are used largely for tanning.

R. GLABRA forms an attractive object by reason of its long, pinnate leaves, which, except that they are not hairy, are very similar in shape and outline to those of *R. typhina*. When planted in good soil the leaves sometimes attain a length of 3 feet, and in some gardens it is a favourite plant to cultivate it for its large leaves. Young plants are given good soil and cut down to the ground-line each year, one shoot only being allowed to develop from each stalk. That shoot becomes very strong and the leaves correspondingly vigorous. When seen in a mass, plants grown in this way are very imposing. The variety *laciniata* differs from the type in having very finely-cut leaflets; it is one of the most beautiful of ornamental-leaved shrubs. *R. glabra* is a native of N.

America and grows about 8 feet high. The leaves of normally-grown plants are each about 18 inches long. In autumn the foliage turns to brilliant shades of red and yellow.

R. HENRYI is a comparatively new species from China which promises to form a small tree. It is chiefly remarkable for its pinnate leaves, which often exceed a foot in length, and for its rather large panicles of green and brown flowers. The red fruits are also ornamental.

R. OSBECKI is a small tree upwards of 20 feet high in its home in China and Japan. Here it may be found as a large bush or small tree. The leaves are very large and handsome, particularly on plants that are cut down to the ground each year. The species is easily distinguished by reason of the winged appearance of the stalk from which the leaflets spring. Like the previous species, it bears large inflorescences, the flowers being yellowish and small, but attractive by reason of their numbers.

R. TOXICODENDRON, the Poison Ivy of N. America, ought to be known to everyone, for it is one of the most dangerous shrubs grown in our gardens, the sap being of an extremely poisonous character when it comes into contact with the skin. It is found as a bush, and also, in the variety *radicans*, as a trailing plant, and it bears, usually, rather large three-parted leaves which in autumn colour brilliantly. Sometimes included in gardens as an unnamed shrub the leaves are collected in autumn and are used for house decoration. A short time afterwards persons who have handled it are troubled by an irritating rash for which they are unable to account. Where this rash has occurred steps should be taken to find out whether *Rhus Toxicodendron* is growing in the garden, and, if it is, the plant ought to be destroyed. It is sometimes known as *Ampelopsis Hoggi*, but has really nothing to do with the group of Vines known under the name of *Ampelopsis*. The second poisonous species is *R. venenata*, or *R. vernix* as it is now called.

R. TRICHOCARPA is a Japanese tree recently introduced to our gardens. It grows 20 feet to 25 feet high in Japan and produces long, pinnate leaves which turn to a rich orange-scarlet in autumn. So far as can be judged at present it is likely to become one of the most useful species for garden culture.

R. TYPHINA, the Stag's-horn Sumach, is, perhaps, the commonest of the strong-growing species, and fine examples may often be noted in suburban gardens. In height it may be met with between 8 feet and 20 feet, with a spreading head of branches, the younger ones being densely hairy. The leaves are pinnate, each 1 foot to 2 feet long, or on cut-back plants 3 feet to 4 feet long. The female plant bears dense, erect heads of fruit which are bright red when ripe. It is a native of Eastern N. America and is easily increased by root cuttings. The variety *laciniata* has beautifully-cut leaves. Both this and the type are sometimes planted in rich soil and cut to the ground each year for the purpose of encouraging fine leaves. The leaves often colour well in autumn.

R. VERNICIFERA is the Lacquer-tree of China and Japan. In its native country it forms a large or moderate-sized tree and the sap is extracted by cutting into the bark as is done when rubber is extracted from various rubber-producing trees. It has handsome leaves up to 2 feet long.

Although these do not exhaust the hardy species of *Rhus*, they include the most useful, and a selection would form a useful asset to any garden. D.

STERILE-FLOWERED VIBURNUMS.

ONE group of the Viburnums is peculiar by reason of their possessing varieties which produce sterile flowers only, or a mixture of fertile and sterile flowers. The sterile-flowered forms are usually the more ornamental, the attractive part of the flowers being petal-like bracts, which are developed in the same manner as in the sterile-flowered Hydrangeas.

VIBURNUM MACROCEPHALUM (here figured) is an example of this group, and the inflorescences are perhaps more like those of *Hydrangea hortensis* than are those of any other species. It is a native of China, and it is doubtful whether the type with fertile flowers is in cultivation. Growing in China to a height of 20 feet, it grows quite 12 feet high against walls in this country. In the south-west counties it may retain its leaves for the greater part of the winter, but in colder places it is usually quite deciduous. Its growth is rather slender, especially when the plants are grown against walls. The flower-heads are often as much as 6 inches across, the colour white. It is one of the most ornamental of all the kinds, but is, unfortunately, tender. Another species which produces sterile flowers is

THE GUELDER ROSE (*Viburnum Opulus*), a European species which is found wild in Great Britain. It forms a large shrub up to 15 feet in height, and bears flat heads of white flowers in which fertile and sterile flowers are intermixed, the blooms being followed by rich red fruits. In the sterile variety the flowers are arranged in globular heads. Another species,

V. TOMENTOSUM, is of Chinese and Japanese origin and grows about 8 feet high. It is easily recognised by its ribbed leaves and flat heads of white flowers, in which fertile and sterile blooms are combined. In the variety *Mariesi* the same combination of flowers occurs in a glorified manner, but in *plicatum* the flowers are all sterile and produced in ball-like masses. *V. t. grandiflorum* is a particularly fine form of this variety.

GARDEN PESTS AND FRIENDS.

THE RASPBERRY-MOTH.

(*LAMPRONIA RUBIELLA*, BJERK.).

THE small red caterpillars of this moth, often called the Raspberry stem-bud caterpillar, are most destructive to Raspberries. On many fruit-farms the crop has been reduced by one-third or one-half in consequence of the attack of this insect, and much mischief is also often occasioned by it in gardens and allotments where patches of Raspberry-canecanec are cultivated. Upon close examination of the attacked Raspberry-canecanec it will be seen that the soft, juicy part at the base of the buds has been eaten away, so as to injure the buds and prevent their foliage and sometimes the blossoms from being put forth. The larvæ also feed on the pith inside the terminal shoots; the attacked shoots flag and then die away in very characteristic manner. A hole in the cane at the base of the buds may often be noticed, in which the pupa will be found ensconced, and sometimes the pupa may be found in the tunnel of the shoot.

DESCRIPTION OF THE MOTH.—The *Lampromia rubiella*, or Raspberry-moth, belongs to the group *Tineina*. It is a most beautiful moth, of a light brown colour, with a series of yellow dots and spots upon its forewings, the two most prominent being on the inner margin. The hinder wings are slightly lighter in colour, with light fringes. The head is yellowish-grey, and the antennæ dull brown. It is barely half an inch across its wings, and its body

is only about the fourth of an inch in length. It may be seen in the end of May, but is most common in June, flying round the Raspberry-canes.

LIFE-HISTORY.—The moth places its eggs upon the flowers of the Raspberry-canes from the end of May to the middle of June. After five or six days the caterpillar may be found in the raised white receptacle upon which the fruit (or, more correctly, the collection of little fruits composing the Raspberry) is formed. The caterpillar does not appear to injure the fruit, nor, indeed, to feed at all at this time. In time the caterpillar makes its way out of the receptacle, either by crawling or by letting itself down by silken cords to the earth beneath the canes, and passes the winter in a flat white silken cocoon about one-twelfth of an inch in diameter. These

what in individuals, and becomes more red in most larvæ as they get older. The head is black, and there is a patch of black divided in two on the first segment. It has three pairs of black feet on the thoracic segments. The pro-legs number four pairs, and there is a pair of anal feet. The pupa is about the fourth of an inch long, tapering somewhat unusually, and has a curious spine upon the back on the last segment; it is reddish-yellow in colour, the wing covers paler, the abdomen somewhat pink.

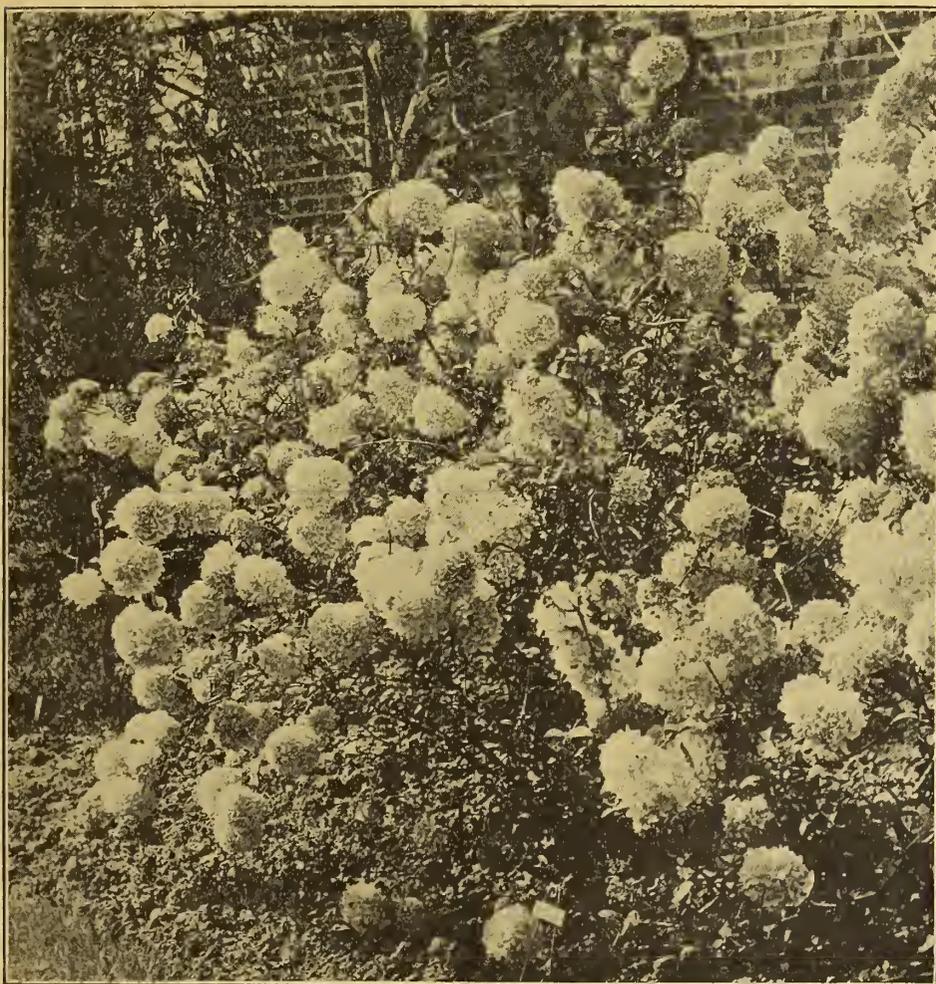

METHODS OF PREVENTION AND REMEDIES.—The caterpillars hibernate just under the surface of the ground, around and among the stocks of the Raspberry-canes, and in crevices in the poles, etc., and, as has been shown, they remain there from about mid-summer until March. Therefore, deeply

would be easy to put some thick soft-soap composition containing paraffin-oil, or some other offensive stuff, with a large paint-brush, at the beginning of March, upon the lower part of each cane that is left, in order to prevent the caterpillars from crawling up, and it would also damage those that may hibernate there. Cutting off and burning the infested canes while the caterpillars are in the buds between April and the beginning of June, would destroy many caterpillars and pupæ. This may be very freely done, as Raspberry-canes throw up plenty of shoots to take the place of those cut away, and infested canes bear little or no fruit. —*Leaflet of the Board of Agriculture and Fisheries.*

VEGETABLES.

PRESERVING SEED POTATOES.

THE aim of all growers ought to be the careful preservation of the seed-tubers, now being stored, in as dormant a state as possible. Nothing in the shape of a heap should be formed. At lifting time let them be separated from the ware and quite the smallest Potatoes—good medium-sized uncut tubers being the best for planting—and kept stored thinly till next spring. Greening Potatoes by exposure to the light and air is so far advisable, inasmuch as it slightly retards sprouting, but this ought not to be brought about by leaving them for several days or weeks lying on the ground or on paths, boards, or mats in the open, as by planting time not a few of the tubers may have taken disease between the lifting and storing times, this being effectually hidden by the coat of green. Tubers thus diseased do not decay rapidly, and perhaps the first indication of its presence is in many cases the weakly growth of the sprouts. Diseased sets cannot support a strong growth of haulm till it has time to become self-supporting, and ought never to be planted. Disease germs are far more plentiful in the air than most of us are aware of, but if they cannot reach the tubers before their skins are dry and well set they will not affect them afterwards, always provided the Potatoes have been properly stored. Dig all tubers that are to be stored in dry weather, and while also the ground is in a semi-dry state. This admits of the tubers being placed under cover or in heaps, and lightly covered up almost as fast as they are dug. It is a mistake to leave a lot of newly-dug Potatoes on the ground to dry all night. Sprouting must be prevented as much as possible by storing thinly as well as exposing the tubers to light and air. Keeping them in single layers, resting in the case of Ashleaves on the smaller end or that previously attached to the plant, cool and fairly light, is the best preventive of premature sprouting and also the surest way of having the sprouts stout and strong when the proper time arrives for growth to be made. Shallow trays with the corner blocks 2 inches higher than the sides are very handy for storing seed-tubers in, as these can be packed one above another and yet not unduly shade each other. Any kind of flat box or shallow basket blocked up well one above the other is preferable to storing in deep boxes, hampers, and such like. The tubers should at planting time be quite firm and the sprouts short, yet how often do cottagers turn them out from a spare room or elsewhere all matted together and shrivelling. Protection must be afforded during severe frost, and if the room or outbuilding when closed cannot be depended on to protect sufficiently, then mats, blinds, strawy litter, or even several coverings of paper, should be used as well.

Viburnum macrocephalum. (See page 558.)

cocoons may also be found in crevices in the poles and under the rough rind of the stems. It emerges from this state of hibernation on the first approach of spring; according to Dr. Chapman it leaves the cocoon early or late in March according to the season. (In 1892 caterpillars of the *Lamproloma rubicella* were first found in Raspberry-buds on April 10th.) It crawls up the Raspberry-canes, and, getting to the bud, worms itself into these at their base, and, feeding upon them, makes up for its long fast during the autumn and winter months. When the time arrives for pupation, the caterpillar scoops out a hole in the pith of the canes, below the base of a bud, in which it turns to a chrysalis, the moth coming out in about twenty-one days. The larva is close upon a quarter of an inch long, decidedly pink in colour for the most part, though the shade varies some-

forking the ground round and between the stocks with a pronged fork, or even hoeing it with a three-toothed hoe, would destroy some and bury others so deeply that they could not get out. Cutting back the canes after an attack, and, as far as possible, doing away with stakes, will have a good effect.

Dr. Chapman has suggested the following practical method of prevention: "The caterpillars are in the crown of the stock, or near it, and under rubbish there collected. Rake this away, and earth the stock up again, and you will thus bury them, and most will perish." Soot, lime, ashes, or soot and lime mixed, which form a pungent compound, might be forked or hoed into the ground in the autumn or winter. When Raspberry-canes in field culture are nearly all cut away, so that there are but few canes or stems left, it

THE WEEK'S WORK.

OPEN-AIR GARDENING.

IN BLOOM OCTOBER 25TH.—*Abelia rupestris*, *Choisya ternata*, *Escallonia montevidensis*, *Grevillea sulphurea*, *Solanum jasminoides*, *Hamamelis virginica*, *Myrtle*, *Jasminum nudiflorum*, *Genista tinctoria*, *Laurustinus*, *Ceanothus* (in variety), *Hydrangea paniculata grandiflora*, *Osmanthus ilicifolius*, *Andromeda floribunda*, *Viburnum coriaceum*, *Hardy Fuchsias* (in variety), *Hypericum*, *Clerodendron Fargesii*, *Lavatera Olbia*, *Phytolius capensis*, *Veronics* (in variety), *Eupatorium Weinmannianum*, *Roses* (in variety), *Clematis* (in variety), *Desmodium penduliflorum*, *Chrysanthemums* (in variety), *Pentstemons*, *Michaelmas Daisies* (in great variety), *Linum arboreum*, *Helianthus* (in variety), *Anemone japonica* (in variety), *Lobelia cardinalis*, *Salvia azurea grandiflora*, *Salvia Greggii*, *Geranium sanguineum*, *Acroclinium*, *East Lothian Stocks*, *Scabiosa* (in variety), *Polyanthus*, *Violets* (in variety), *Gazania splendens*, *Antirrhinums*, *Clematis* (in variety), *Pyrethrum uliginosum*, *Chrysogonum virginianum*, *Sedum spectabile*, *Aubrietias*, *Androsace lanuginosa*, *Shamrock Pea* (*Parochetus communis*), *Gysophila muralis*, *Heeria elegans*, *Ethionema coridifolium grandiflorum*, *Lithospermum prostratum Heavenly Blue*, *Linarias*, *Dwarf Campanulas*, *Corydalis thalictrifolia*, *C. lutea*, *Meconopsis cambrica* (Mexican Poppy), *Mesembryanthemums*, *Armeria Lauchean rosea*, *Convolvulus mauritanicus*, *Polygala Chamæbuzus purpurea*, *Omphalodes cappadocica*, *Valerian*, *Ononis natrix*, *Hardy Cyclamens*, *Crocus speciosus*, *Sternbergia lutea*, *Amaryllis Belladonna*, *Erigeron mucronatum*, *Tufted Pansies* (in variety), *Menziesias*, *Ericas*.

WORK OF THE WEEK.—The planting of spring-flowering plants and bulbs is now completed. The weather has been ideal for planting, and such as Wallflowers, *Myosotis*, *Arabis*, *Alyseum*, etc., lifted with good balls of soil, never flagged after planting. In certain borders that are filled exclusively with Wallflowers the soil was made very firm at the time of planting, as this causes the plants to make slow, but steady, growth, thus enabling them better to withstand severe frosts. The present weather is most favourable for the transplanting of shrubs, particularly evergreens. This is the best season of the year for the work, as the plants will have time to recover from the disturbance before winter sets in. If the soil is in the least dry it will be necessary to give a good soaking of water after planting, making a basin around the stem of each plant for the purpose. Periodical thinning out is a necessity among thriving trees and shrubs, and is much to be preferred to continual clipping and pruning, for, treated thus, neither trees nor shrubs have the least chance of developing their full beauty. Of course, cutting out or shortening an occasional strong or misplaced shoot should, and must, be done. The replanting of hardy herbaceous plants may now be proceeded with. Planting at this season has many advantages, for, whether new borders are to be formed or the plants in those already existing merely divided and rearranged, it is best done when the weather is open and the nature of the various subjects may be still identified. Most herbaceous plants need replanting about every third year, and where it is intended to renovate already existing borders or to plant fresh ones, the ground should be thoroughly well trenched and enriched, as, unless they are given a fairly rich, deep-rooting medium, they suffer during prolonged periods of drought. Before trenching is attempted, care must be taken to dig up and lay by in a convenient place near at hand the whole of the plants, taking every precaution to preserve the labels of the various kinds. The plants should be laid in the soil temporarily or well covered with mats or some other material that will protect the roots. F. W. GALLOP.

Lilford Hall, Oundle, Northants.

SOUTHERN COUNTIES.

Primulas, Chinese.—These must no longer be left in pits. They require a rather warmer temperature than *Cinerarias*, otherwise the same kind of house suits them well. Those

which will soon be coming into flower should be placed at the warmest end of the house, and the same with regard to double varieties, particularly the old Double White variety, if the plants cannot be accommodated elsewhere. If the roof glass is at all dirty it should be washed before housing the plants, as it is essential that they receive all the light possible. Younger plants coming on to form a succession should have their flower-spikes pinched out as they push up to induce them to become of good size before being allowed to bloom.

East Lothian and other Stocks.—These, if not yet potted, should at once have attention, putting one plant into a 3-inch pot, and, after watering, standing on a shelf in a greenhouse well up to the light. Failing such a position, a pit containing a bed of ashes near enough to the glass to prevent the plants becoming drawn, will, if frost can be excluded when necessity arises, answer, as they require but little warmth.

Mignonette.—Seedlings raised in August should be finally shifted into the pots in which they will bloom and be returned again to the same position near the roof glass. The second batch of plants now needs to be thinned down to five in each pot.

Cyclamens.—The earliest flowering batch of plants must now have careful attention, both in regard to airing, watering, and in maintaining the bed on which the pots are stood in a moist condition. As the flower-stems are now pushing up, stimulants must be afforded. The nature of these should be varied. A course of soot-water, followed by Clay's fertiliser, and the latter by liquid-manure, answers well, or the last two may also be given. In any case, whatever is used should not be given in too strong doses, otherwise the tender, fleshy roots will be quickly destroyed. Keep a careful watch on the foliage, and vaporise at once should thrips be detected. Admit air from the front by the ground ventilators only, in order to avoid draughts, also sufficiently at the top so that the temperature ranges between 55 degs. and 60 degs. A higher temperature than this will lead to the foliage and flower-stems becoming drawn and the flowering period considerably shortened.

Onions.—Wet weather having given weeds an opportunity to go ahead and partly smother the young plants in the drills, the beds have been hand-weeded and the ground between the rows afterwards hoed through.

Cauliflowers.—These should be looked through daily when all that are not sufficiently advanced for cutting must be protected from frost by breaking the outer leaves over the heads. If properly done this is sufficient protection for some little time to come. Autumn Broccoli now turning in requires attending to in the same way.

Vegetable Marrows.—These being over for the season the bine has been cleared away, while the beds can be wheeled out the first opportunity or when the ground is rendered firm enough by frost.

Flower garden.—*Antirrhinums* and *Michaelmas Daisies* are still making a fair display, but with regard to what are known as summer-bedding plants, these are past their best for the season, and should be removed and the beds filled at once with spring-flowering subjects, for which Wallflowers of the *Phoenix* type should be freely employed. Large specimen plants in tubs and pots are no longer safe in the open, and should, therefore, be housed at once. When greenhouse space is limited, many of these may be placed in a disused coach-house or stable, if the same are fairly well lighted. The fall of the leaf has commenced in earnest, and occasions much work in the way of clearing up. Lawns also now need the final mowing and the verges trimmed, after which the machines can be housed until the times arrives for sending them to the makers to undergo their annual cleaning and refiging.

Propagating.—It is not too late to propagate more *Pentstemons*, *Calceolarias*, and *Violas*. The matter should, however, be no longer delayed, and a cold pit or frame with eashes in good repair should alone be used. Such as are leaky from want of paint or loose putty, and are, as a result of so much moisture,

dripping inside the structures and causing great loss among the inmates are unsuitable, and should never be employed. The cutting beds should be made up as close to the glass as is compatible with safety. A. W.

MIDLAND COUNTIES.

Bush fruits can easily be propagated from cuttings, the present being the most suitable time for the work. The shoots of the current year are the most suitable. The cuttings should be made about 10 inches long. Cut square across below a joint, and remove all eyes but four at the top, cutting off the point of the shoot so as to concentrate the sap into the four remaining eyes, from which the branches of the future tree are formed. Insert them firmly 4 inches deep in rows 10 inches apart and 4 inches from each other. Firmness at the base is most essential. A partially shaded spot is the best situation for them. A mulching of coal ashes will, to a great extent, prevent frost lifting the cuttings. The object of cutting away all buds except the few at the top is to ensure clean, straight stems, free from suckers. In the case of Black Currants, the finest and best fruit is produced on young shoots of the previous year's growth, and suckers are an advantage, therefore no buds should be removed from the cuttings at the time of insertion. The present season is also the best in which to make plantations of bush fruit, and to fill up any gaps. When filling gaps, do not plant the young trees in the same place, and among the roots of the old bushes. First remove all the old roots, whether decayed or not, and also a sufficient quantity of the old soil, which should be replaced by fresh, in which the young trees should be planted. If trees large enough to be swayed by the wind are planted, these should be staked immediately after planting. In the case of Apples, Pears, and Plums, a triangle is better than one stake. At the time of writing, the ground is in excellent condition, and the sooner the planting of all kinds of fruit-trees is carried out the better will be the results next spring.

Vineries.—Grapes which are still hanging on the Vines need to be examined two or three times each week for the purpose of removing any decayed berries, also faded leaves. A cool and dry atmosphere is necessary for keeping ripe Grapes in good condition. The vineries are well ventilated during favourable weather, and a little fire heat is necessary in dull, damp weather. Pot plants which require frequent watering should not be placed in vineries in which there are ripe Grapes. Vines may be pruned a month or six weeks before they are required to be started into growth. Generally, the laterals may be pruned to two eyes, but the older the Vines the longer should the laterals be left. After the pruning has been done it will be necessary to thoroughly cleanse the rods and houses. Wash the rods thoroughly with Gishurst compound, being careful not to injure the buds. If the Vines have been attacked by mealy-bug they should afterwards be painted with the following mixture: One pint of gas tar, two wineglassfuls of paraffin, a 60-size pot of flowers of sulphur, and three pints of clay. Boil these materials, adding sufficient water for thinning. In applying this mixture, take care that it does not touch the buds. After the inside of the house has been thoroughly scrubbed with hot water and soft soap (to which a little paraffin should be added), remove the old and loose soil from the surface of the border, and if the soil is found to be dry, water well, then give a top-dressing of new compost composed of rich fibrous loam, adding a 6-inch potful of an approved Vine manure to each barrowload of soil. Apply a good mulch, and the house will then be ready for starting. The roots in outside borders should be protected with a good mulch of stable-litter.

Begonia Gloire de Lorraine.—The earliest batch of this is now in full bloom, and is very useful for decoration. Later batches are growing freely, and require occasional attention in the matter of tying the shoots. Ventilation is afforded with care, the night temperature ranging from 55 degs. to 60 degs., according to climatic conditions. *Salvia azurea grandiflora*, now coming into flower, has been placed

in a light, dry house, where a temperature of 50 degs. to 55 degs. is maintained at night, with a good circulation of air during the day.

Asparagus.—The plants in the permanent beds having completed their growth, the stems will be cut down and burnt. The quickest and best way of clearing the Asparagus growths is to use a pair of hedge shears. Clear the beds of all weeds and give a light mulch of well-decayed manure, which should be covered with a little soil from the alleys. Salsafy has been lifted and stored in sand.

Potatoes that were lifted two or three weeks ago and stored temporarily will be examined at the first opportunity before placing them in pits for the winter. When the tubers are being sorted, those intended for next season's planting will be selected and placed in single layers in shallow boxes. These will be stored in a frost-proof shed where ventilation can be freely afforded in mild weather. Potato "sets" treated in this manner give better results than those left in a heap until spring.

Onions in the store need to be examined at frequent intervals, throwing out any that are likely to decay. If left too thickly, many are sure to go wrong. An occasional turning will be beneficial.

Green vegetables.—Collect all decaying foliage so as to admit as much air as possible between the rows, which will help to harden the plants before winter sets in. The soil between the rows should be stirred and the ground cleared of weeds.

Preparations for next season's crops should be commenced as soon as possible. Advantage should be taken of dry days to wheel manure on to the different plots which are in need of trenching. Before much ground work is carried out the necessary arrangements for next season's cropping should be decided upon. The system of rotating the crops is of the utmost importance in vegetable culture; but, as so much depends on the nature of the soil, the size of the garden, and the different products required, no hard-and-fast rule can be laid down in this matter. As most of the ground that is ready, or will soon be ready, for digging has recently produced root crops, this ground should be next cropped with Peas or some sort of Brassica. Onions may be successfully grown on the same plot of ground for several years in succession, provided it is well prepared each year.

Mushrooms.—Horse-droppings are being collected and placed in an open shed, where they can be turned frequently in preparation for making the beds. It is necessary to turn these droppings, previous to their removal to the Mushroom-house, four or five times, to allow of the escape of gases. The turning is repeated after the droppings have been placed in the Mushroom-house until all danger of sourness is over. This bed will be spawed at a falling temperature of about 80 degs., and the surface of the bed covered with sifted loam to a depth of about 1 inch. An atmospheric temperature of 55 degs. to 60 degs. is maintained in the house without fire heat.

F. W. G.

SCOTLAND.

Cuttings.—It is now time that all cuttings were under cover; therefore, during the week this has been attended to. Such things as Zonal and Scented-leaved Pelargoniums have hitherto been standing in a sheltered place out-of-doors. These have rooted well, and, having been relieved of withered foliage, were placed in pits heated by hot-water pipes. In these pits cuttings winter very well. During the dull months much more damage results from damp than from any other cause, so the pits are freely ventilated on all suitable occasions. Meantime, to dry up the moisture, a slight heat will be found serviceable.

Zonal Pelargoniums.—A good batch of these—intended for spring flowering—has been put near the glass in heated pits. These plants are very serviceable after the latest Chrysanthemums have passed out of bloom, and require but little attention during the winter. Being in robust health, they will require a little top-dressing, and this will be given them at an early date. A little well-rotted loam, with a

sprinkling of soot, always suits Zonal Pelargoniums. During the winter only sufficient water to preserve the plants in good health is necessary. In the course of the week a few dozen cuttings of approved varieties were put in, these making very useful material in the course of a twelvemonth when brought along coolly.

Chrysanthemums.—Housing has now been completed in the case of the latest varieties. The earlier blooms are expanding freely, and promise to be quite satisfactory. Stimulants are now withheld, and in order to keep down damp, no superfluous water is thrown about in the house. It is annoying to find that an outbreak of rust has resulted on plants grown from imported cuttings. We had been clear of this pest here previously, and in order to get rid of it the worst offenders have been burned and those slightly affected have been isolated until the blooms can be cut. No cuttings will be taken from these plants. I fancy that rust is one of the results of over-feeding. Ventilation must be ample in the Chrysanthemum-house, and on dull, wet days, or on frosty nights, a little fire heat may with advantage be allowed. If the house has not yet been vaporised, this should not be longer delayed. Two light vaporisings on successive nights ought to be sufficient.

Fuchsias.—Looking round the borders the other day, I was struck by the fine display made at this late date by the hardy Fuchsias, especially *F. gracilis*, *F. globosa*, and a variety grown—incorrectly, I think—under the name of *F. hybrida*. The thought suggested itself that a batch of these in, say, 5-inch pots, would be very useful at this season of the year for cool greenhouse decoration, more especially in view of the shortage of bulbs. A considerable number of cuttings was, therefore, taken, and to facilitate rooting, these were put into the propagating-case. When rooted, it is intended to pot them off, and keep them moving quietly until late spring, when they can be plunged in the open air until required. The experiment is, at all events, worth a trial, and should it succeed, the display afforded in late October or early November will be welcome.

Primulas.—In the course of discarding plants which were grown on a stage covered with crushed granite, a fine little colony of thriving and sturdy seedlings of *Primula sinensis* was discovered. They were put into pans, and will, no doubt, come in useful round about the end of April. Seedling plants of different kinds have, from time to time, been salvaged from the crushed granite referred to. Among others, a good supply of *Schizanthus wietonensis* was obtained; so, too, was a sufficient number of *Primula malacoides*. *Lobelia* seedlings appear at frequent intervals; and it would seem that the substance and the conditions favour the germination of seeds and the development of seedlings. It is, therefore, intended to experiment by sowing on the granite (at the proper time) such things as *Cinerarias* and *Calceolarias*.

Cleaning houses.—The weather having broken down, a beginning was made with the cleaning of glass-houses. Paint, glass, and woodwork of all kinds are thoroughly scrubbed with hot soapy water to which has been added a little paraffin, which clears out the less harmful insects, such as spiders, etc. In old houses where the woodwork may be beginning to decay, woodlice are almost sure to be present. I would not like to say positively that these insects are injurious to plant life; but they ought, if possible, to be cleared out. Boiling water poured down their haunts quickly disposes of the vermin; and isolated specimens can be trapped by means of slices of Potato and destroyed. Woodlice, too, will eat phosphorus paste, and can be cleared out by the use of that substance. In cleaning houses, all wires, ventilating rods, and so forth may be washed down with paraffin, and when any given house is finished off it ought to be thoroughly syringed down with clean, cold water.

Outdoor work has, temporarily, been interfered with by heavy and incessant rains. The only work which has been done was the planting of a considerable quantity of Wallflowers.

W. McGRFFOG.

Balmæ Gardens, Kirkcudbright.

ROYAL HORTICULTURAL SOCIETY.

OCTOBER 24TH, 1916.

The fortnightly meeting held on the above date was decidedly small, a result of the recent severe frosts, which had cleared off the Dahlias as well as the majority of hardy flowers. Roses which a few days earlier were full of promise shared a like fate, though quite good flowers came from the Romford district. At the same time there was much to interest, including herried shrubs, while Violets have never before been presented in such quantity or excellence, and they justly merited one of the highest awards given at this meeting. Nerines, too—the hardy *N. Bowdeni*, in particular—were a great attraction. The common *Gentianella* was again good, Carnations being well shown. The great bank of Orchids from Haywards Heath was, however, the chief attraction, and, while rich in variety, displayed considerable taste in arranging. A few bunches of Grapes were also staged.

HARDY FLOWERS.

The collection of Violets presented by Mr. J. J. Kettle has never before been equalled. Rich in variety, embracing both single and double sorts, the wealth of them, as much as their perfect condition, found many admirers. A central mass of the pure white *Comte de Brazza* was very fine, the red lavender coloured *Mrs. J. J. Astor*, the silvery mauve-blue *Mrs. J. J. Kettle* (a recent addition as well as an acquisition to the race), and the rich lavender *Colcroonan* were the best among the doubles, though *Jamie Higgins* (large silvery-mauve), was also excellent. Of singles, *La Bourg Lorraine*, *La France*, and *Princess of Wales* were the pick. Mr. G. Kerswell again had a considerable display of *Gentiana acaulis*, showing how perpetual-flowering this unique plant is in some localities. Plants of considerable interest were shown by Mr. G. Reuthe. These included rare shrubs and some novelties. Notable among them were *Pilostegia viburnoides* (with white cymes of flowers), *Thibaudia acuminata*, with scarlet flowers not unlike those of *Brodiaea coccinea*, the pure white *Escallonia pterocladon*, and *Arbutus Croomei* (which has white globe-like flowers). *Desfontainea spinosa*, the scarlet and gold flowers as good as ever, had not felt the frost. *Saxifraga Fortunei*, *S. cortusaeifolia* with *Crocus pulchellus*, *C. p. albus*, *C. speciosus albus*, and *C. medius* (reliable and good at this season) were, with an excellent lot of Nerines, also on view. Without doubt, the best hardy bulbous plant shown was *Nerine Bowdeni*, which Mr. F. Lilley brought from Guernsey in some quantity. A brilliant successor to the *Belladonna Lilies*, and hardly less hardy, it merits the attention of all who like flowers of rare colouring at this season.

SHRUBS.

We thought *Acer tataricum* *Ginnala* an elegant plant with finely-pointed, deeply-lobed leaves, well staged by Messrs. J. Cheal and Sons, Limited, the most brilliant-coloured subject at the meeting. In the sunlight the intense scarlet would be most attractive. *Cotoneaster frigida* (scarlet fruited), *C. Simonsi* (also scarlet), and *Hypericum Androsæmum* (blackish fruits) were shown among others. *Pernettias* in variety were also on view. A collection of Conifers and other shrubs from Mr. L. R. Russell included the rare *Fitzroya patagonica*, *Ilex Peryni*, and *Daphniphyllum macropodum*. *Retinospora tetragona aurea* was notable and good. A table of *Berberis* and other shrubs from Messrs. Wallace attracted much attention. The most notable plant was *Berberis Wilsonæ*, its branches laden

with brilliant red fruits. It is the best of its set, albeit the seedlings show considerable variety both in fruiting and colour brilliancy. *B. Coryi*, as shown, is not freely fruited. *Stranvassia undulata* also bears clusters of scarlet fruits, and sweeping the ground at first, presently rises to a goodly bush. The two best trailing Junipers for big rockwork or bold groups, *J. tamariscifolia* and *J. procumbens* were also shown.

GREENHOUSE PLANTS.

A novelty in this section was *Solanum aculeatissimum inermis*, a spineless sport from the type. The scarlet fruits are small, deeply corrugated, as in the old strains of Tomatoes. Excellent *Nerines* were shown in groups by Mr. Frank Lilley. The central group was of *N. elegantissima* (of rosy-carmine colour). *Garibaldi* was very brilliant, and not less striking *N. eoruscans major*, which has closely-fashioned heads of flowers. *N. crispa* is a dainty sort apart from these, and of lilac colouring. *N. pudica* and *N. flexuosa alba* (white) were also shown. Messrs. Barr and Sons also showed *Nerines*, the most charming variety being *N. Isolde* (pale salmon-pink with deep rose at the base). It is very beautiful. Choice Ferns from Messrs. H. B. May and Sons included *Adiantum Faulkneri*, *A. Veitchi*, *Pteris Lawrenceana* (with much cut fronds), *Todea Vroomii*, *Litobrochia gigantea*, and a fine group of *Polypodium glaucum crispum* (a plant of high beauty and ornament).

CHRYSANTHEMUMS.

Messrs. W. Wells, Limited, arranged an excellent lot of these, the whole characterised by youth and freshness. Chiefly of the decorative set, they appealed to many. We were struck with the new *Anemone-flowered Aphrodite* (pink in colour, and very good). *Sorcerer* (rich bronze), *Ethel Harvey* (golden incurved), *Cranford Yellow*, *Uxbridge Pink*, *White Hope*, and *Supreme* (large white single) were others. Messrs. Godfrey and Sons staged a collection of singles raised by the firm. Effective (bronze), *Mrs. Harold Philip* (pink), *Golden Crown*, and *Exmouth White* were the more distinct. Exhibition novelties in this section were *Dawn of Day* (a mingling of gold and bronze) and *Mrs. Algernon Davis* (of good pink tone). Each gained an Award of Merit. Mr. Norman Davis was the exhibitor.

CARNATIONS AND ROSES.

Very fine Carnations were staged by Messrs. Allwood Brothers. *Destiny* (cerise), *White May Day* (with all the free-flowering attributes of the original), and *Nancy*, a new American pink-flowered sort of promise, were among the best. *Wivelsfield White* we considered far and away the best of its class. It is large and very pure. *Bishton Wonder* is the most fragrant, and *Triumph* the brightest crimson. The only exhibit of Roses was that from the Rev. J. H. Pemberton, Romford, a district, judged by the flowers shown, that might have been immune from frost. *Lady Pirrie*, *Rayon d'Or*, *Mme. Abel Chatenay*, *Gustave Regis*, *Gustave Grunerwald* (rich pink) were all good for late October. *Damaea*, *Moonlight*, and other cluster-flowered sorts were also of fair quality.

ORCHIDS.

The group of these from Messrs. Charlesworth and Co. was, in these strenuous times, in the nature of a revelation. A hundred or so of plants of the orange-scarlet *Epidendrum vitellinum autumnale*, each carrying three or four racemes of flowers, constituted, with the pure white *Odontoglossum armainvillierense xanthotes*, a fine centrepiece to a group rich

elsewhere in *Cattleyas*, *Laelio-Cattleyas*, *Odontiodas*, *Odontoglossums*, and much besides. *Cattleya Enid Reine Blanche* was very pure and good. *Odontoglossum grande* was also freely introduced. Of special interest was a batch of home-raised examples of *Disa grandiflora*, the brilliant flowers telling and welcome at any season. Orchid novelties from Messrs. Armstrong and Brown included *Brasso-Laelio-Cattleya The Baroness* variety, *Golden Beauty*, *Cattleya Prince John* (Orchidhurst variety) (Award of Merit), *C. Saturn alba*, *C. labiata alba*, and *C. Ajax* (Orchidhurst variety). A dark blotched seedling *Odontoglossum* was named *Doris*. In a group from Messrs. Sander and Sons, *Cattleya Thebes* variety *Britannia* stood out conspicuously—a fine contrast of golden petals and brilliant ruby-erimson lips. It gained a First-class Certificate. Equally conspicuous was the pure white *Laelio-Cattleya Schilleriana* var. *Sanderæ* and *Cattleya Fabia* var. *Memoria Lord Roberts*. Sir Jeremiah Colman, Gatton Park, sent a series of *Cattleya Aleimeda cœrulea* crosses, Colonel Stephenson showing the rarely seen pale-blue flowered *Cattleya Mrs. F. D. Godman*. Mr. E. G. Mocatta, Woburn Park (gardener, Mr. T. Stevenson), had a lovely novelty in *Odontoglossum Menier*, which, save for white-tipped sepals and pure white lip, has a ground colour of rich chocolate. First Class Certificate. Messrs. Flory and Black gained Awards of Merit for *Cattleya Alexandria* (rich ruby-purple and velvet-erimson lip) and *Brasso-Cattleya Mars* var. *xantholeuca*, which is white, pink, and golden-orange. Messrs. Hassall's contribution included *Cattleya Iris*, *Brasso-Cattleya Queen Alexandria* (white), and *B.-C. Nestor*, of rosy-mauve colouring.

A complete list of the plants certificated and medals for groups will be found in our advertisement columns.

CORRESPONDENCE.

PLANTS AND FLOWERS.

Phyllocactus, insects on (*Old Woman*).—The two growths of *Phyllocactus* you send have been attacked by scale and mealy-bug, the best remedy for which is to wash every shoot with paraffin emulsion or Gishurst compound, following carefully the instructions sent with the insecticides. Very probably you will find that one application will not get rid of the pests, and you will have to watch they do not reappear. Should this happen, then one of the above remedies should be again applied.

Verbena venosa (*A.*).—This is the name of your plant. It is a perennial kind, 12 inches to 18 inches high, with heads of purple-violet blossoms, hardier than ordinary *Verbenas* and not so liable to mildew. It is easily kept through the winter, and if its fleshy roots are stored thickly in boxes it may be easily increased in spring from the young growths. When the plants have to be lifted in the autumn place them into boxes, keeping them during the winter in a cool place until the spring, when they may be started in heat. If allowed to remain in the ground a covering of ashes or fibre placed over them will be quite sufficient for them.

Dahlias, lifting and storing (*R. T. Codd*).—When the frost has cut down the *Dahlias*, cut off the stems 9 inches from the ground, then, with a fork, lift the roots carefully, taking care not to break the fleshy tubers. Shake off some of the soil or remove it with a pointed stick, turn the roots bottom upwards to allow any water that may be in the hollow stems to run out, and when the roots are fairly dry place them in shallow boxes as closely as you can, and cover them up with dry soil or ashes well shaken in, and then stand them in some place where frost cannot reach them, and where it is fairly dry—not under drip. So cared for, the roots should keep well all the winter. Next spring stand them on a hothead, so as to provide cuttings should you wish to

increase your stock of any of the sorts you have. If not, after being well started and hardened off, you can plant out the old tubers.

FRUIT.

Treatment of Fig-trees (*W.*).—A wall with a south aspect is the best place for Fig-trees, and with good cultivation they ought to bear freely. Many persons allow the shoots to become too much crowded, so that they cannot ripen; and unripened wood of any kind will not bear fruit well. Stopping the shoots early in the year will cause the formation of many more, which will further crowd the tree with wood. The shoots may be stopped with advantage late in the season, which will throw them into fruit instead of into growth. Thin out the wood well now, and if there are any long shoots stop them; they will not now start into growth.

MISCELLANEOUS.

Worms in lawn (*Moreton*).—Lime-water is the best remedy. Place 12 lb. of unslaked lime into a barrel and pour over it 30 gallons of water or a like proportion, stirring it well up and allowing it to stand for 48 hours. Water the lawn with the clear liquid during damp weather using a rose pot, giving a good soaking of the lime-water on the evening succeeding that on which rain has fallen or after a good soaking of water has been given. This will bring the worms to the surface, when they may be swept up and cleared away. There are now on the market several worm-killing powders, which, no doubt, can be had from some of our horticultural sundriesmen.

SHORT REPLIES.

L. S. Sweeney.—1, Your best way will be to leave the plants as they are until they flower, when you can then destroy all inferior kinds and layer any that are worth keeping. 2, *Spiræa Anthony Waterer* may be moved now, while, as regards *S. Queen Alexandra*, you can, if you wish, lift it and pot it to be forced gently. In the spring, when done flowering, you may then break it up and replant it.—*H. P.*—Yes; you can procure seed, but the seedlings are a mixed lot, containing many plants with inferior flowers. Hence, the best way is to purchase plants, and save seed from the best forms.—*G. W.*—*Nepeta Mussini* is quite hardy, and can be divided up to any extent. The cuttings will take no harm if they are put out at once—that is, provided they are well rooted.

NAMES OF PLANTS AND FRUITS.

Names of plants.—*J. P.*—1, *Aster Amellus* var. *bessarabicus*; 2, *Aster Novi Belgii* var.; 3, *Helenium autumnale grandiceps*; 4, *Euphorbia Lathyris*.—*R. T. W.*—1, *Francoa ramosa*; 2, *Leycesteria formosa*; 3, *Aster ericoides*.—*Inquirer*.—1, *Begonia ascotensis*; 2, *Begonia metallica*; 3, *Sedum carneum variegatum*; 4, *Berberis Aquifolium*.—*Mrs. Bertonshaw*.—A white form of the annual *Larkspur*.

Names of fruits.—*A. H. W.*—Pears: 1, *Marie Louise*; 2, *Glou Moreau*. Apples: 3, *Cellini*; 4, *Emperor Alexander*.—*Arrow*.—Apples: 1, *Ecklinville*; 2, *Bramley's*; 3, *Cox's Orange*; 4, *King of the Pippins*.—*B. M.*—Apples: 1, *French Crab*; 2, *Tower of Glamis*; 3, *Wellington*; 4, *Warner's King*.—*W. A.*—Apples: 1, *Hawthornden*; 2, *Blenheim Orange*; 3, *King of the Pippins*; 4, *Lane's Prince Alhert*.—*J. S.*—Pears: 1, *Brown Beurré*; 2, *Doyenné du Comice*.—*C. S.*—Apples: 1, *Leathercoat Russet*; 2, *Rymer*. Pears: 3, *Louise Bonne of Jersey*; 4, *Durondeau*.—*T. M. Y.*—Pears: 1, *Beurré Claireau*; 2, *Beurré Bosc*; 3, *Forelle or Trout Pear*; 4, *Doyenné Boussoch*.—*M. H. E.*—Pears: 1, *Marie Louise*; 2, *Fondante d'Automne*. Apples: 3, *King of the Pippins*; 4, *Bramley's*.

PEMBERTON'S ROSES

What people say of them:—"The Finest Plants I have ever received."—"Both lots were splendid."

Price List and Guide to Selection post free for Two-pence.

FLOWER-GARDENING AT KEW.

A LETTER sent as to the article on the state of the flower-garden at Kew is so far off the issue that we cannot insert it. To give an idea of the value of some of the things said, I quote what is said about pergolas:—

The pergolas at Kew are as satisfactory as any I have ever seen in England, which is not saying much for them. Pergolas are nearly always ugly, and they certainly would be an outrage in front of the Palm-house at Kew.

The pergola is the best thing ever introduced in our time to the British garden, and far better than the old nailing to the wall or any other way of growing the noble climbers of the world, from the Wistarias to the great coloured Vines. It can give shade, as it does in the south of Europe, but also because we can grow more climbers upon it than can be grown in the scorching sun of Italy or Eastern America. We can have climbing Tea Roses, climbing China Roses, and other fragile creepers that will not put up with a hot sun. I write looking at one which goes from a house and garden on the south side of a hill leading directly to the fruit and vegetable garden, and in so doing in the pleasantest way it also shelters the garden from the north wind in a position where a wall would be out of place. Climbing plants of high value take their natural toss and form as in no other way in gardens.

The writer says he does not know a better pergola than that wretched thing of wire and tinker's stuff at Kew. I could show him half-a-dozen better. Having had some experience of such things I have learned the danger of meddling with them, and that to give the best result one must have an architect to design one of an enduring and very strong nature. The weight of Wistaria and other great climbers before the wind is such that only a well-built structure will survive it. A pergola to lead from the Palm-house to the water (now abandoned to ducks) would be the finest thing ever put up at Kew for growing and showing the beauty of the great climbers.

There is a pergola in Herts designed by Sir E. George and nobly covered with climbers which would open the eyes of all interested in the growth of climbers.

W. R.

NOTES OF THE WEEK.

A handsome Torch Lily (*Kniphofia Gunton Park*).—I enclose you a bloom, which I consider very good. The flowers are not at their best, having been nipped by the frost. The best are now over.—A.

[A large and handsome flower at end of October. We suppose it was raised at Gunton.—Ed.]

The Blue Lettuce.—I am pleased to see what a good picture was made of the Blue Lettuce, at page 531. The plant figured is not *Lactuca Plumieri*, but *L. Bourgei*, the handsomest of all, with stiff stems of good tufted habit. Please put this right. It would be so wrong to lead people to plant *L. Plumieri* in the hope of getting the effect shown in the picture.—E. A. BOWLES.

Osmanthus armatus.—This is a remarkable evergreen species from Western China, the firm, leathery leaves of fine substance, each 4 inches to 6 inches long, armed with curved spines at the margin. The creamy-white flowers are fragrant and produced in autumn. Though of slow growth, good plants were noted among shrub exhibits at a recent meeting of the Royal Horticultural Society.

Montbretia Star of the East.—Those who wish to have the finest *Montbretia* in commerce may confidently purchase *Star of the East*, although it is still high in price. It is a magnificent flower, 5 inches round when well grown, and of a glorious colour—pure orange-yellow with a lemon-yellow eye, and of fine substance. It remains still the best of Mr. Davison's new *Montbretias*.—S. ARNOTT.

Nerine Bowdeni.—From the Exeter Nurseries of Messrs. R. Veitch and Son, who say, "Our outdoor border of *Nerine Bowdeni* is a sight worth seeing," comes a bunch of flowers of this handsome Cape plant grown in the open ground. This very fine addition to our open-air flowers seems hardy at Exeter, and we hope it will prove so in many other places. Warm and sheltered borders are the most likely to lead to success. It would be charming to have such a graceful group of plants in the open garden.

Verbena radicans.—Those who like trailing greenhouse plants which are not generally met with might give a thought to *Verbena radicans*, a native of the Andes. It is altogether distinct from the usual forms of the flower, the foliage being much cut, the trailing stems producing their pale lilac blooms at their terminals. Of comparatively rapid growth, *V. radi-*

cans is easily increased from cuttings, and, apart from its value as a plant for draping, it might possess a further value as a basket plant, a purpose to which it would seem to be specially adapted.—KIRK.

The nobler Fuchsias in the flower garden.—In my flower garden now the ordinary hybrid varieties make a brave show, and are precious for those who enjoy their gardens in October; but handsomer far, both in foliage and flower, are some of the wild kinds, as *F. corymbiflora* and *F. fulgens*. Of the former I have a white variety. Both are charming in the graceful, drooping flower-tassels, both kinds have beautiful leaves, and both thrive in the same way as hybrid kinds—in slight shade and good cool soil.—W.

Berberis Darwini.—Now (October 21st) we are having a fairly good display, for the second time during the season, of the orange sprays of Darwin's Barberry. This is not uncommon in these gardens, but during the present year, when cold and wet have been so conspicuous, it was thought that the second bloom might not appear. However, in spite of drawbacks, there is quite a cheerful display—more welcome at this time when everything is assuming a wintry look. It may be said that in open years *B. Darwini* has bloomed uninterruptedly until after the New Year.—W. McG., *Balmoe*.

Rose Charles E. Shea.—This new "H.T." is one of the "gold medal" Roses of the year, having gained that honour in June last, when shown by the raiser, Mr. Elisha J. Hicks. We do not expect Roses so good in October as in June or July, yet a stand of it on the 10th of that month at the fortnightly meeting of the Royal Horticultural Society proved its excellence. It was, indeed, the finest of many Roses shown on the date mentioned. Large, shapely, of clear pink colour and fragrant, it caught the eye at once. Exhibited forced early in the year, in June, and in October it promises well all round. It will not be sent out till next year.—E. H. J.

Aster Novi Belgii Brightest and Best.—This we thought highly of when recently shown. There is a warm, rosy-red effect about it that would prove cheerful in the garden in autumn, when Sunflowers, Golden Rods, and blue and lavender coloured Michaelmas Daisies hold sway. The nearest in colour to Brightest and Best are Sirius and Lustre, and while the latter is the more richly coloured of the two, the newcomer constitutes an advance. Those requiring brilliant effect under arti-

ficial light at small cost should cultivate Asters of this shade, either in pots or otherwise. Like the cerise tones in the Carnation, they light up well, an enhanced beauty not theirs in the light of day resulting.

Rose Marquise de Sinety on own roots.—Led by the nose by the trade in grafting every Rose on the Brier, we have long lost many of the best and most beautiful Roses. The question is a little difficult from the fact that many kinds appear to thrive on the ordinary trade stock. Going into the garden on October 20th, I gathered some striking flowers from a vigorous plant, and wondered what it was, until, on looking closer, I found it was a plant struck from a cutting of Marquis de Sinety two years ago. In the same garden the worked plants are ugly stubs, neither growing well nor flowering freely.—W.

Aster Novi Belgii J. S. Baker.—This novelty was shown in excellent condition by Messrs. Baker, Codsall, on October 10th, when it gained an Award of Merit. It is, so far as I remember, the first double white Michænas Daisy, and, as shown, quite pure and good. As seen, it would appear a fitting companion to the first double blue, Beauty of Colwall. The doubling in these so far, however, is not complete, and both, at maturity, are liable to show a yellow disc or centre. This notwithstanding, the newcomer is likely to be in demand by florists, quite apart from its value to the hardy plantsman.—E. H. J.

Solanum jasminoides at Sheffield Park.—The most picturesque wall plant I have ever seen at the end of October was this beautiful rambling shrub in huge masses on the house at Sheffield Park. Trained on the house, the shoots hang free, with enormous masses of flower, 40 feet or so high. It is in a narrow border, no doubt well nourished, but in front of this is a stone-paved path, where the roots are kept cool. A native of Brazil, probably in some cool mountain region, as it thrives so well in our climate and on the cool side of the house. I found a pale azure form in cultivation in France, and grew it for some years on too hot a wall. It did not seem so good as the white form, but deserves a trial. No plant I know is so nobly "decorative" in late autumn. In hot soils it thrives on the north side of the house.—W.

Ourisia coccinea.—I fear I have unwittingly been the cause of some heat being engendered in connection with the discussion on this plant. Knowing the long experience and keen observation of Mr. Jenkins, I am always unwilling to differ from him on the question of the treatment of hardy flowers. My desire was to show, virtually, that there is no "royal road" to success with it, and I hope I stated my position in a temperate way. I am amused at the suggestion that I am taking shelter behind Mr. Cornhill. It is surely justifiable to cite the opinions of another without being accused of taking "shelter." Even in such a small matter as the cultivation of flowers one may be allowed to quote the words "magna est veritas et prevalebit." The verdict of experience will show who is right.—S. ARNOTT.

Aster ericoides Desire.—This I look upon as the most beautiful and graceful of the modern varieties of this elegant species. It is not sufficient praise to refer to it as a pure white form of the type, its outstanding merit demanding more than this. Endowed with the grace and charm common to its class, it is still of a superior character, the sprays as welcome when cut as the whole plant in the garden. Of moderate height—3 feet or so—it is well suited

to small gardens or for filling large beds, where, if not bundle-tied to a single stake, it will attract everybody fond of a good plant. All the ericoides forms possess a neat stay-at-home root-stock, and from a 5-inch ground tuft may, with due consideration, produce a floral display 3 feet across. Hence they need different treatment from the majority if they are to give of their best. Notwithstanding the restricted nature of the root-stock this Aster can be readily divided and pay for it in common with other sorts. A. e. Desire makes one of the prettiest pot plants I know, whether raised from cuttings each year or grown from small divisions. Potted and plunged their full depth, occasional waterings will be all that are necessary to bring about good results.—E. H. J.

A rosy Sage (Salvia Greggii).—I saw this beautiful Sage in good condition during mid-October; indeed, so bright and fresh were the abundant rosy-erimson flowers that it struck me as being a valuable plant for summer beds. It is a native of Texas. A warm and not too rich soil suits it admirably, and small plants struck from cuttings in February make useful stuff for planting in the open about the end of May. These commence flowering almost immediately, and so continue until quite late in the autumn. I do not know what amount of frost this fine Sage will endure, but a plant came through unprotected last winter in Sussex and is now 3 feet high, producing long, slender sprays of its charming and distinct flowers.—E. M.

—Among novelties of the year, this native of northern Mexico is good, a dwarf Sage, with deep rosy flowers and a distinct and neat habit. That is how it looks in the flower garden. In another place in the Azalea beds it forms a shrub about 18 inches high. It has been out-of-doors all last winter, untouched by frost. It is among the best of the Sages, flowering in good time and lasting until the end of October. Some of the Southern Sages (*S. azurea*) are of little value owing to their flowering so very late in autumn, and then never opening well with us, though they do better in S. France.—W.

Tuberous Begonias in the flower garden.—Like "E. B. S." (page 516), I thought that "Kirk" underestimated the value of the tuberous Begonia for the flower garden. As pointed out by "E. B. S.," they present a bright and cheerful appearance when such subjects as Pelargoniums are very bedraggled. With the amount of wet that we have experienced during the present autumn this has been particularly noticeable. One point more in favour of tuberous Begonias is that they do not occupy much room during the winter. "E. B. S." recommends those with erect rather than drooping blossoms for the outdoor garden. Still, there are a few of these latter with pointed petals, more after the type of one of the original species, *Begonia boliviensis*, that are good. Of them may be mentioned Bertini, Bertini nana compacta, and Worthiana, all with flowers of an orange-scarlet shade. The two varieties referred to by "E. B. S." I do not know, and most probably they are now superseded. Quite a dwarf race of Begonias with double flowers well above the foliage has come prominently forward within recent years. Included among them are Argus (scarlet), Calliope (pink), Gambetta (orange-scarlet), Hollyhoek (deep pink), Lafayette (erimson-scarlet), Mrs. French (creamy-white), Mrs. Langtry (white), Rev. E. Lascelles (yellow), and Washington (bright orange-scarlet). A variety much used for the flower garden is Major Hope, whose double pink flowers have a picotee edge of a deeper tint,

Though not belonging to the tuberous-rooted section, the different forms of *B. semperflorens*, of which there is now such a great variety, are also of great service for the summer garden.—K. R. W.

The white Heliotrope a failure.—Depatures from the natural colour of a flower are not always happy, no more than hybrids are not always real gains; white forms, too, are often failures. I have enjoyed M. Lemoine's seedling Heliotropes now for some years, the vigorous growth and varied purple blooms often striking one as better for the flower garden than the named varieties. But this year I, in some unsought way, got a batch of a white form, also one reputed pink, and the effect of these was wholly bad. I have written to M. Lemoine begging of him to keep on with this noble purple and get us as free of the whites as he may.—W.

GARDEN PESTS AND FRIENDS.

NOTES AND REPLIES.

Tomatoes diseased.—Kindly tell me if the Tomatoes I send you are suffering from Potato disease? The plants have been heavily manured this year, but I had the same diseased fruit last year. I shall be glad of your opinion as to the cause.—G. R. PARKER.

[The Tomatoes sent are affected with black-rot disease, which is present in a more pronounced condition in one specimen than in the other. The fungus germs in this case could have attacked the fruit only through a wound or puncture of the skin. In some cases the germs find an entrance near the style, and the black patch then develops at or near the apex of the fruit. The fungus is also present on the stems and leaves when an attack occurs. All diseased fruits should be burnt forthwith. Another season, if Tomatoes are to be grown in the same house, remove all old soil and thoroughly cleanse and disinfect the house. Then, when fruits are set and swelling off spray the plants with liver of sulphur, whether the disease is present or not, and continue this treatment at intervals right through the season. Use 1 oz. of the sulphide to 4 gallons of water. To make, first dissolve about 2 oz. of soft soap in 1 gallon of hot water, then add the sulphide, and finally dilute to make up 4 gallons with soft water. Apply with a spraying syringe. If the solution should not be found of sufficient strength to check the disease, *i.e.*, if it re-appears, increase the quantity of sulphide to 1½ oz. for the same quantity of water.]

Silver-leaf on Plum-tree.—One of my neighbours had a Victoria Plum-tree affected on the leaves with a silvery dew. The gardener told the neighbour that the disease was known as silver-leaf. Now one of my trees has become affected, and I am anxious to take means to stop it. I have asked a leading gardener, but he says it is a new disease, but no cure is known. Can you help me in this matter?—KENDAL.

[We know of no cure for the disease known as silver-leaf, with which your Plum-tree is affected, and the best plan is to root out and burn a tree so soon as it becomes affected with it. If you intend planting another tree in the same place then it would be well to remove the old soil, as there is just the possibility of the root-system being contaminated if you leave it. If you plant any other tree barring a stone fruit you need not remove the soil, but see to it that every particle of the roots of the Plum-tree is cleared out, as such, if left, would engender fungus as they decay. A dressing of lime given a few weeks before planting would do good. Use fresh lime, and well incorporate it with the soil by well forking it in.]

TREES AND SHRUBS.

SOME ATTRACTIVE MYRTLES.

ALTHOUGH the Myrtles are not hardy enough for general cultivation in the British Isles there are many places in the south and west where they succeed, and they there introduce a very pleasing feature into the garden. Three species are usually grown, all being evergreen and succeeding in ordinary garden soil. They can be increased by cuttings of half-ripe

with great freedom during September. The fruits are black and are sometimes borne profusely.

M. Ugni, also known as *Eugenia Ugni*, also from Chile, is as hardy as the last-named and grows as tall, but is less showy when in flower, and the leaves are less glossy. The flowers are often tinged with pink and the fruits, which are sweet and reddish, are edible and sometimes used for jam.

M. communis, the common Myrtle of S. Europe, is a beautiful and popular plant,

HARDY FUCHSIAS.

It is not often that one night's frost causes such a complete collapse of the hardy Fuchsias as was the case on October 21st last, and it was the more regrettable because up to that date they were flowering profusely. It was also rather surprising to note that what one would have supposed to be shelter was of no avail, several plants close under a south wall being badly cut. Although the plants come safely through the majority of winters, there are times when they succumb,

Myrtus Luma (syn. *Eugenia apiculata*).

shoots inserted in sandy soil in a close frame in summer, and good bushes are soon formed.

MYRTUS LUMA (syn. *Eugenia apiculata*), the subject of the accompanying illustration, is, perhaps, the most generally useful of the various species, and is in every way a very excellent shrub whether from a foliage or flowering point of view. A native of Chile, it has long been grown here, where it forms a handsome bush often more than 12 feet high, well proportioned, and well branched from base to summit. The pure white flowers are borne

its oval, dark green leaves being very fragrant. In the warmer parts of the country it forms a large bush in the open; elsewhere it may be grown on walls or in tubs to stand out on terraces during summer, being stored in a cold greenhouse for the winter. The white flowers, borne freely during September and October, are followed by black fruits. The variety *tarentina* is of more compact habit with narrower leaves, and one form with bluish-white fruits is sometimes called *M. communis leucocarpa*. *M. communis* is the hardiest of the three species. D.

notably in the February of 1895, when very few were left, especially where the practice of mulching the roots thickly with leaf-soil or ashes had been neglected. They are such a beautiful race of plants and so acceptable at a time when other flowers are scarce, also, given immunity from frost, the flowering season is so prolonged that it is a wonder the hybridist has not taken them in hand with the view to greater variety. Of course, one gets variation in the way of habit of growth, size, and shape of flowers, and so on, but the colour, alike of sepals and corolla, is prac-

tically the same, and I have often thought what a grand and enduring display could be made if even a few of the different colours of the greenhouse varieties could be obtained in the hardy sorts. There are not many hardy plants of a similar height and season of flowering that associate well with Fuchsias, and so one has to use isolated plants unless the family is grouped, the only variety being furnished by the variegated form of *F. macrostemma* or *F. gracilis*, the variegation in this case being rather pleasing and not very pronounced as in the case of some plants.

When using these Fuchsias in a large bed they can, if deemed advisable, be planted rather thinly on a carpet of, say, Tufted Pansies. I noted above that not many hardy plants associate well with these Fuchsias, but exception might be made in the case of *Yucca filamentosa*. I have seen these used together very effectively. Both show to advantage on a sloping bank among rough stones and the like, there being dwarf forms of the Fuchsia, like *F. pumila*, which can be used towards the base of the slope. Some of the greenhouse sorts can be used in such planting if variety in colour is wanted, but these are different in habit from the hardy sorts and not so well adapted for such situations. E. B. S.

Hardwick.

Cotoneaster humifusa.—I know of nothing to equal this neat-habited, evergreen, trailing kind for clothing a sloping bank in a moderately cool or even partly exposed situation. Discovered growing in rocky places and crevices in Central China, it appears equally adapted to like places in lowland gardens. I have in mind a rocky slope 8 feet or 10 feet deep and of fully the same extent perfectly clothed by the plant. Of ravine-like character, at some little distance from a big waterfall, and with high rock and trickling water near, the position is fairly cool and the plant thrives apace, affording a perfect sward of its neat green leaves bedecked in early autumn with small scarlet fruits. Elsewhere, with fuller exposure and removed from the cooling effects of near-by water, the plant still grows well, and, if of a modified luxuriance, still maintains a characteristic density and neatness. For banks with weathered rocks occasionally in sight the effect would be fine, indeed.—E. H. JENKINS.

Fuchsia microphylla.—While this Mexican species of Fuchsia may prove hardy in the favoured climate of South Devon, as detailed by your correspondent, T. A. Hyde (page 543), it requires in most districts the protection of a greenhouse. It, and the nearly allied *F. thymifolia*, are great favourites of mine, but here, in Surrey, to the south-west of London, neither of them can be depended upon to pass the winter safely out of doors. Trained to the supporting pillar of a greenhouse it will mount up several feet and produce its tiny brightly-coloured blossoms in great profusion. The other species, *F. procumbens*, mentioned by T. A. Hyde, is hardier than the preceding, but with me it is more satisfactory in the greenhouse than it is out of doors. For a hanging basket it is well suited, for the long, slender shoots hang down a considerable distance, the upright, quaintly-coloured flowers being borne freely. Its second phase of beauty sets in when the fruits ripen. I have tried to cross this Fuchsia both with other species and garden varieties, but in no case have I been able to obtain good seed, though, left to itself, fertile seeds from which young plants may be raised are obtainable. There is, however, no need to use seeds, as cuttings root readily.—K. R. W.

PLANTS AND FLOWERS.

INDOOR PLANTS.

IXORAS.

THESE very showy stove-flowering plants may be had in bloom over a lengthened period. They are particularly valuable during the autumn, when comparatively few stove plants are in bloom. Last autumn a splendid group was shown at one of the meetings of the Royal Horticultural Society, and attracted a very large share of attention. Some take exception to Ixoras on the ground that they are particularly liable to the attacks of mealy-bug, but with attention this pest can be kept in check. If the insects have been allowed to make headway a good plan is to syringe the plants thoroughly with paraffin emulsion, and if any stragglers appear after this a drop of methylated spirit will ensure their death. With regard to the potting compost many prefer to use fibrous peat, with a mixture of silver sand, but I have obtained the best results by using one-third loam to two-thirds of peat, and a good sprinkling of sand. In the culture of Ixoras too dry an atmosphere must be avoided, otherwise thrips are very liable to attack the foliage. To obviate this a liberal use of the syringe, especially during hot weather, is necessary. Ixoras are not at all difficult to strike from cuttings if the half-ripened shoots are selected, put into pots of peat and sand, and plunged in a gentle bottom-heat in a close propagating-case. At one time they were largely grown as specimen plants, but they can also be well flowered in comparatively small pots.

Many seedlings have been raised from time to time, but many of the so-called varieties greatly resemble each other. A few good kinds are *acuminata* (white), *coccinea* (orange), *coccinea lutea* (yellow), *Fraseri* (salmon-carmine), *Prince of Orange* (orange), *Pilgrimi* (orange-scarlet, shaded crimson), *Westi* (pink), and *Williamsi* (reddish-salmon). To these must be added the distinct *macrothyrsa* or *Duffi*, a strong, upright grower with long leaves and very large heads of rich crimson-red flowers. K. R. W.

TREATMENT OF HYDRANGEAS.

1. I WOULD be much obliged if you will tell me when I ought to repot my *Hydrangea* cuttings. I have a large quantity, taken in August, in 3-inch pots. They are for cold greenhouse only. 2. What size pots ought I to use for some *Hydrangeas* from cuttings of the summer before (1915)? Would 8-inch pots be right? 3. What do you consider the simplest way of obtaining blue *Hydrangeas*? Is it sufficient to pot in a mixture of one part iron filings and five parts peaty loam? If possible, I do not want to use liquid applications which need to be repeated frequently and for a long time. I suppose by using the iron filings I would not need to use much of any liquid applications?—R. N. F.

[1] If your *Hydrangeas* are well furnished with roots they may be potted now. Pots 5 inches in diameter will be a very suitable size, and a desirable compost may be made up of two parts loam to one part peat or leaf-mould and one part of equal portions of silver sand and dried cow-manure if you have any. If not, it may be omitted. After potting, the plants must be given enough water through a fine rose to settle the soil. Then, during the winter, they should be given sufficient water to keep the soil fairly moist, but not too wet, as they are in a dormant state. In the New Year, when growth re-commences, more water will be required. Any plants not well rooted may be left till February

of next year before they are repotted. (2) Those that were cuttings in 1915 may be put into pots from 6 inches to 8 inches in diameter, according to their strength. (3) The reason of *Hydrangeas* turning blue is by no means thoroughly understood. It is usually put down to the presence of iron or some chemical substance in the soil, but, even if this is the case, the reason of a plant producing some blue and some pink flowers is not explained. You may, with a fair chance of success, pot your *Hydrangeas* in the suggested mixture. We would, however, point out that peaty loam appears to be a poor soil for such a plant. *Hydrangeas* may be turned blue by watering with a solution of alum, but they need persistent attention in this respect, which you do not wish to give. There is a compound known as Azure, the vendors of which give the following directions for its use:—"One heaped teaspoonful (half an ounce) placed on the surface of a 6-inch pot plant just when the bud is showing is all that is required. The usual watering of the plant completes the treatment. For large plants in tubs the surface of the soil should be sprinkled over with Azure in a proportionate quantity, and, with extra large specimen plants, a second dressing in two weeks' time will be necessary. Always water the plant carefully." To this we would add use rain-water if possible, and avoid water with chalk in it.]

HOLDING FAST BY WELL-TRIED PLANTS.

IN a description of a new double Ivy-leaved *Pelargonium* (GARDENING ILLUSTRATED, August 26th) the writer thinks it may be some time before it supersedes one or two old favourites, and this raises the question as to many things among well-tried plants, both outside and under glass, that hold their own against later introductions. In Ivy-leaved *Pelargoniums*, for instance, Galilee, that has been grown for the last thirty years, has few, if any, superiors, either for pots or outside work, whether in beds in the open, in vases, or window-boxes. If one wants a bit of glowing colour in Zonal *Pelargoniums* it can hardly be better supplied than by Paul Crampel and King of Denmark. For beds of a similar character, as noted in the case of Galilee *Pelargonium*, the older Fuchsias and *Heliotrope Piccoli* hold their own against all new-comers. Also for outside planting one is reminded that among semi-hardy things nothing has been found in fine-foliaged plants to supersede or even equal *Grevillea robusta*, which, for a light, graceful effect, is unequalled. Its value, too, as a pot plant was recalled the other day by seeing in a large cottage window a couple of well-grown plants flanking a clean, healthy-looking *Aspidistra* 50 per cent. of whose leaves had pronounced variegation. This latter, by the way, is another of the well-tried things. I always think one of the mysteries of plant life is how the *Aspidistra* preserves its vitality and freshness under circumstances that would be fatal to the majority of plants. I have a plant growing in a 6-inch pot that has been in the same pot and position (a sitting-room window) for the past four years. It has forty-seven leaves, about one-third variegated, and every leaf as near perfection as possible. Whence the nourishment is derived to support all this foliage is wonderful, as there can be very little in the pot except roots, practically no soil, and the only stimulant ever given, and that only a few times in the middle of summer, is a sprinkling of Clay's fertiliser before watering. There is certainly nothing in the way of fine-foliaged

plants that will give to the ordinary householder for room decoration such a good result at a minimum of trouble and expense.

E. B. S.

Hardwick.

CALLOPSIS VOLKENSI.

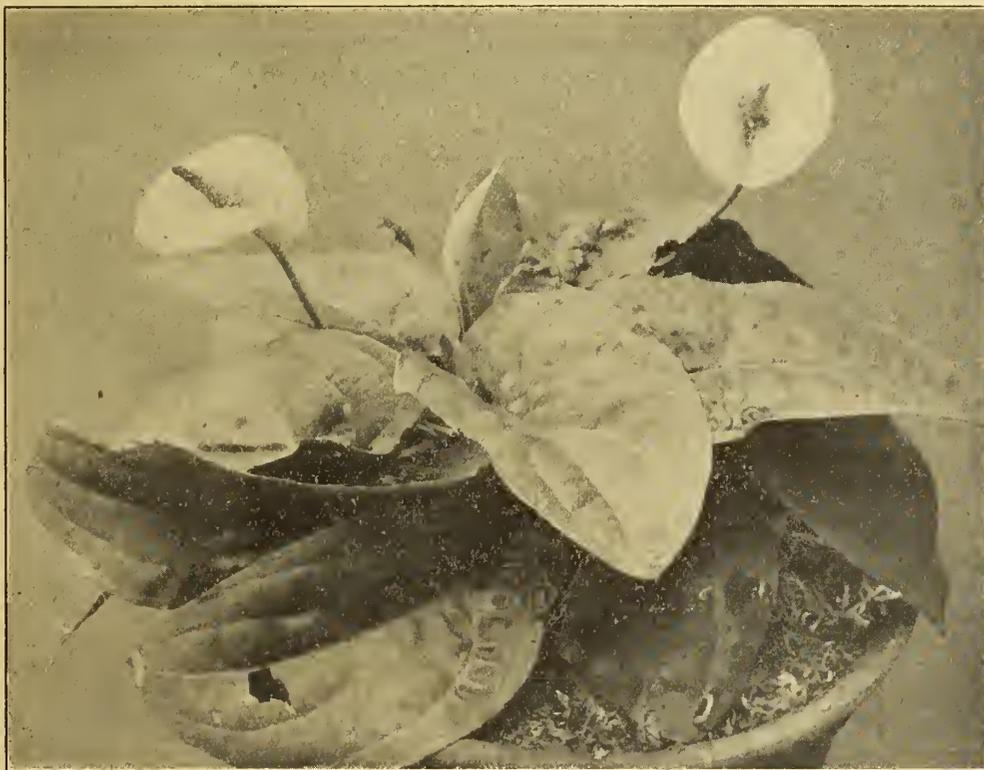

This is an interesting tropical plant belonging to the Aroid family, but it is rare and little known outside botanic gardens. It is a native of East Africa, where it was discovered, according to the *Botanical Magazine*, t. 8.071, by Dr. Volkens, at the foot of trees in the forest on Mount Msasa. It was originally introduced to the Royal Botanic Garden, at Dahlem, near Berlin, and from there a plant appears to have been sent to Kew in 1905. In habit it is a dwarf perennial with an underground rootstock. Several leaves appear in clusters from buds on the rootstock, the leaves being oblong and up to 5 inches long, exclusive of the stalk. The inflorescence consists of a short yellow spadix enclosed in a white spathe an inch

tub, will succeed for years without being disturbed. In this case an occasional stimulant will be very beneficial during the growing season. Cuttings of this *Clethra* are not at all difficult to root if formed of the half-ripened shoots, dibbled firmly into sandy peat and put into a close propagating-case in gentle heat.—W. T.

Winter-flowering Carnations.—Year-old plants are now beginning to yield good blooms in abundance. Disbudding and the keeping of the plants in order as regards tying and picking off older leaves as they become discoloured should receive due attention. To maintain the plants in good health and in a flowering condition Carnation manure is applied periodically. A number of plants which had fallen into a rather neglected condition has been, as they could not be altogether dispensed with for the present, cut back. A gentle dewing with a syringe and keeping the house rather closer than usual have induced them to break well, and in a short time they will be well furnished with

sary. Those required to flower early may now be fed with mild doses of liquid-manure or soot-water twice or thrice in a week. Caterpillars are apt, if overlooked, to greatly disfigure the foliage. Partaking, as they do, of much the same colour as the leaves, it is necessary to well scrutinise the under sides of the leaves to be able to detect them. The shelves in this house provide congenial winter quarters for *Schizanthus Wisetonensis* and the large-flowered hybrids.—K. P.

Potting materials.—There is at all times of the year a certain quantity of potting to be done, and, in view of the approach of the damp season of the year, it is now advisable to get a sufficient quantity of potting materials under cover in order that it may be in a suitable state of dryness when required. Loam may be put in roughly chopped up, leaf soil may be sifted and stored, and while it is not so important to keep sand under shelter, yet it is as well to store a quantity in a shed so that it will not be sodden when it is needed. A wet day or two will provide time for the washing, grading, and storing of dirty pots,

Callopsis Volkensi. From a photograph in the Glasnevin Botanic Gardens, Dublin.

or so long and almost as wide. The flowering extends over a period of about three months. It requires stove culture, and succeeds in rather loose and rich soil.

W.

NOTES AND REPLIES.

Clethra arborea.—Some fine-flowering sprays of this *Clethra* were noted at the meeting of the Royal Horticultural Society on September 12th. It is a native of the Canary Islands, and, unlike most members of the genus, is strictly evergreen; in fact, it is, in general appearance, somewhat suggestive of an *Arbutus*. The pure white flowers, a good deal after the manner of those of the Lily of the Valley, are disposed in spikes freely scattered over the specimen. Summer and early autumn are its season of blooming. Grown in large pots or tubs, it is very useful for lofty conservatories. It may, if wished, be stood outside during the summer. This *Clethra* will do well in a mixture of loam, peat, and sand, and, if in a large pot or

healthy growth. When growth becomes rather more advanced than it is at present all will be given a shift into larger pots. These plants should yield a large quantity of blooms in the spring months.—K. P. S.

Cinerarias.—Unless the pits in which the plants have been grown are heated they should, seeing that frost may occur at any time now, be moved into a greenhouse which can be heated sufficiently to ward off frost when occasion arises. A bed of ashes or a stage covered with corrugated sheet-iron with a good layer of ashes on top forms the best medium to stand the plants upon, for, being cool and damp, such material provides most congenial surroundings for them. The house should be liberally ventilated whenever possible, to keep the plants dwarf and sturdy, and for the same reason each specimen should stand wide enough apart for air to circulate freely between them. The plants should be looked carefully through each morning and the needs of the roots supplied in the way of water as may be neces-

which always accumulate in the autumn. Crocks, too, may be washed and graded. This is generally considered to be superfluous work, but it pays to devote a little time to cleansing them. Unwashed crocks may, quite conceivably, harbour injurious spores or the eggs of injurious insects. When a boiler is handy, if the water is raised to boiling point, the pots which are immersed are not only sterilised, but are made much easier to wash.—W. McG.

Hydrangeas.—Many prefer large pieces of Hydrangeas in pots to smaller plants carrying but a single head. Nevertheless, the latter are very handy in many ways, and I always grow a batch of such plants. During the week stout cuttings of partly-ripened wood, each carrying a plump bud in embryo, were put into the propagating-case. With a little bottom-heat these soon root, and can be grown on until they reach the desired size in respect of pot. Naturally, the more root-run allowed, the better is the bloom; but for general purposes, pots 4 inches in diameter are large enough. Hydrangeas are rather gross feeding and thirsty subjects, so that stimulants may be rather freely administered, and copious supplies of water are needed to keep the plants in health.—W. McG.

FRUIT.

NOTES AND REPLIES.

Apple Ribston Pippin.—It is not often one sees a healthy tree of this old favourite, though, no doubt, soil plays an important part in this respect. A few years since I was asked by a local gentleman to try a stock of Ribston he possessed and which he claimed to be canker-proof. I accepted scions, but the trial has not borne out his theories of canker immunity. The Apple is quite typical in appearance, with the crisp texture of the original stock, but the tree, as remarked, has in our soil been attacked by canker. Held up as it has been as typical of the highest grade of what a dessert Apple should be, it is somewhat strange that raisers have not used the Ribston for hybridising. Cox's Orange Pippin has been largely used as a parent, the aim, presumably, being to get a more hardy and vigorous stock, combining the same favoured quality, but, so far as my experience goes, none of the Cox's progeny has the same flavour as the original. Neither Chas. Ross nor the Houblon can lay claim to the high standard of flavour, though they have exterior beauty and certainly a more vigorous growth.—W. S.

Pear Belle Julie.—A most prodigious cropper, it is not to be expected that the fruit should be of large size, but it has the much more important character of good flavour. In this cold and sunless season, and one which for me is nearly Peerless also, a Pear which will develop its full flavour is valuable, and Belle Julie has this quality. The fruit is of a nut-brown russet, touched with a warmer shade on the sunny side, and attains about 3 inches long by 2 inches wide. The eye, exactly like a Clove, is set in a shallow basin. The flesh is extremely melting, not gritty, sweet, and delicately flavoured, ripening about the middle to end of October. The tree forms a compact pyramid or cordon, and the only special care needed is to thin the fruit when a prolific crop is set. This is one of the many fruits we owe to Van Mons, and it was named after his granddaughter.—*Gardeners' Chronicle*.

Apple Warner's King.—This is always recommended as bearing plenty of pollen, and my own experience bears this out. I have two bushes in a small orchard, and although this season has not been particularly prolific as regards Apple crops, it was remarkable how heavily laden with fruit were the bushes situated in the near neighbourhood of these two trees. James Grieve, Allington Pippin, and Pott's Seedling were the immediate neighbours in one case, and each of these trees was loaded with fruit, the branches of Pott's Seedling being literally weighed down with Apples. Warner's King is a very good Apple for cooking, but it is not a great bearer with me. It is, however, worth planting if it helps its neighbours to bear good crops.—N. L.

Fruit-trees in pots.—Any necessary repotting may be attended to at the present time. In some cases, during the present state of affairs, the annual potting may be superseded by the removal of a proportion of the soil from the pots and the substitution of fresh, mellow loam. It should be borne in mind that Peaches, Plums, Nectarines—stone fruit generally—must have a certain proportion of lime in the compost. Above all, whether potting or top-dressing be practised, the ball must never be allowed to feel the want of moisture, for the slightest dryness at the roots will, beyond doubt, result in bud dropping. If the trees are not yet for any reason out-of-doors, let the house be fully ventilated both by day and by night in order that the wood may be hardened and matured.—W. McG.

GARDEN FOOD.

AUTUMN FRUIT.

AMONG the exquisite fruits now obtainable mention should be made of the delicious Grapes, which are plentiful, good, and cheap. Those of England and the Channel Islands are large, handsome, and luscious. The Black Hamburg is exceptionally fine in quality, and the same may be said of the Alicante. So far as flavour is concerned, those two varieties are easily first in the category of dark Grapes. Both are cheaper than the Gros Colman, which commands a higher price because of its magnificent appearance.

ATTRactions OF SIZE.—It is futile to argue about the payment of extra money for size and colour in fruit. The public have decided long ago that they prefer beauty to flavour, and as they rule in the matter no useful purpose will be served by telling them that they are wrong. A prolonged campaign of common-sense would be needed to teach people that Grapes of large size and deep purple colour are not necessarily the best. The Gros Colman is a very fine Grape, but at this time of year it does not equal in flavour either the Hamburg or the Alicante. It is the best of the winter black Grapes, and only by comparison can anything disparaging be said about it. The Gros Maroc is even better in appearance, but not nearly so good in quality as the Colman.

Specially fine are the two Muscat varieties. If only the public knew how delicious are the cheap Muscats now on the market, but few pounds of those Grapes would remain unsold in the shops. Excellent bunches of the Muscat of Alexandria can be bought for 1s. per pound, and the fact of the berries being small is immaterial. Again, elegance must be paid for, and Muscats, both of the kind named and the Canon Hall, are much dearer when large and handsome than if diminutive in size. All Muscats are good, no matter whether or not they please the eye, so that consumers may buy the Grapes with the fullest confidence that they will be satisfied.

Peaches, though not exactly the fruit of the poor, are comparatively cheap. The early crop of this delicious fruit was not heavy, but the later varieties have come along well. Just now there is a magnificent display of very large Peaches, most of which are excellent in every way. For the benefit of those who like to know the varieties available, the following may be mentioned:—Sea Eagle, Exquisite, Golden Eagle, Lady Palmerston, and Princess of Wales. Prices vary from 6d. to 2s. 6d. each retail, a fair medium quotation being from 8d. to 1s.

TOMATOES.—Large quantities of Tomatoes have appeared at Covent Garden during the week. Amongst the cheapest are those of Jersey grown out of doors. These are of rich, sweet flavour, and in every way suitable for domestic use. There is no justification for a higher retail price than 4d. per pound for Jersey Tomatoes.

[*This from the "Telegraph": A writer could not do a worse turn to fruit-growing than praise fruit for its looks. Fruit poor in quality does harm in all ways to fruit-growing and to fruit-eaters. The Grape Alicante is not worth growing. What makes the great difference in value between a Newtown Pippin and any sour Apple in our market?—the quality only.—Ep.]*

The Potato Onion.—In the issue of October 28th, page 544, the Potato Onion is mentioned. I am an old man and a gardener, and have

often heard of the Potato Onion, but have never yet seen one, and know nothing of its growth. I have wished to try it several times, but have never done so. Would you kindly give in an early issue directions for its cultivation?—POTATO ONION.

[This variety of Onion more frequently forms a cluster of underground bulbs of irregular shape than a single round bulb. It produces neither seeds nor bulbils, and is increased only from the bulbs which are formed underground. If fairly strong bulbs are planted as early in the spring as the ground can be had in working condition, well-grown bulbs may be had from them in the following June. If, however, the bulbs are allowed to attain maturity, instead of a single bulb from each, seven or eight of various sizes will be produced. The strongest of these will in their turn produce a number of bulbs, the weaker ones only growing into a single bulb. The flesh of the Potato Onion being milder than that of the ordinary Onion, it is preferred by many people. We have found it a good plan when the bulbs are growing freely to draw some soil up to them. When it is seen that the bulbs are ripening off, this soil may be removed in order that sun and air may reach them. This Onion likes good, deep, well-manured soil, and single sets should be planted about 9 inches asunder with 9 inches between the rows. If the ground is soft the bulbs may be simply pressed into the soil, but if firm then it is well to draw out a shallow drill and set the bulbs in this. You will find an illustration of the Potato Onion in our issue of April 8th of this year, p. 185.]

Sweet Corn in 1916.—In spite of the cold summer my crop of this was good. I grow the best American varieties, and think the result a great addition to our garden food resources. The Corn is most pleasant in flavour and very wholesome. It is best gathered when of medium size, as when getting on towards ripeness it is not nearly so good.—W.

"**Intilt.**"—I often in my childhood heard the amusing story of the Frenchman's difficulties with "intilt" told of Queen Victoria. She was very young, and went into an old woman's cottage, and whoever was in attendance on her had not the Gaelic. Unlike the Frenchman, I was told, she got into a truly royal rage at the repetition.—R. NOLAN FERRALL.

Food Economy.—Some fatuous suggestions are being made about this. One is that, instead of meat, one should have for a meatless meal twenty oysters. This footing about such a simple matter as a meatless meal makes one suspect that these writers have never heard of the nations of Europe whose food is almost entirely meatless—such peoples as the Serbians, Bulgarians, Italians, and others, not to mention the working Irish, who do not even taste meat once in the week. We see another writer states that "vegetarian dishes and dishes of cereals cannot become palatable with the majority of English people." This is only because such dishes and cereals are badly cooked. Cereal food is not only the best, but is delicious if properly cooked and served. Take, for example, the Italian ways of cooking rice, macaroni, and simple vegetables. It is quite easy to dine and thrive upon such dishes. That strength comes from eating flesh more than from other foods is a delusion, as is proved by the fact that the strongest races in Europe and Africa are not flesh eaters. Also it is well known to students of human physiology that where the healthy peasant—Irishman, Pole, or Italian—settles in and does well in a city, and begins to eat flesh, he soon loses his fine health and drops into gout and rheumatism, and becomes often a creak of disease and misery.

OUTDOOR PLANTS.

A GARDEN SHELTER AT MYDDELTON HOUSE.

I HAVE been asked to write an account of the construction of this little shelter from sudden showers.

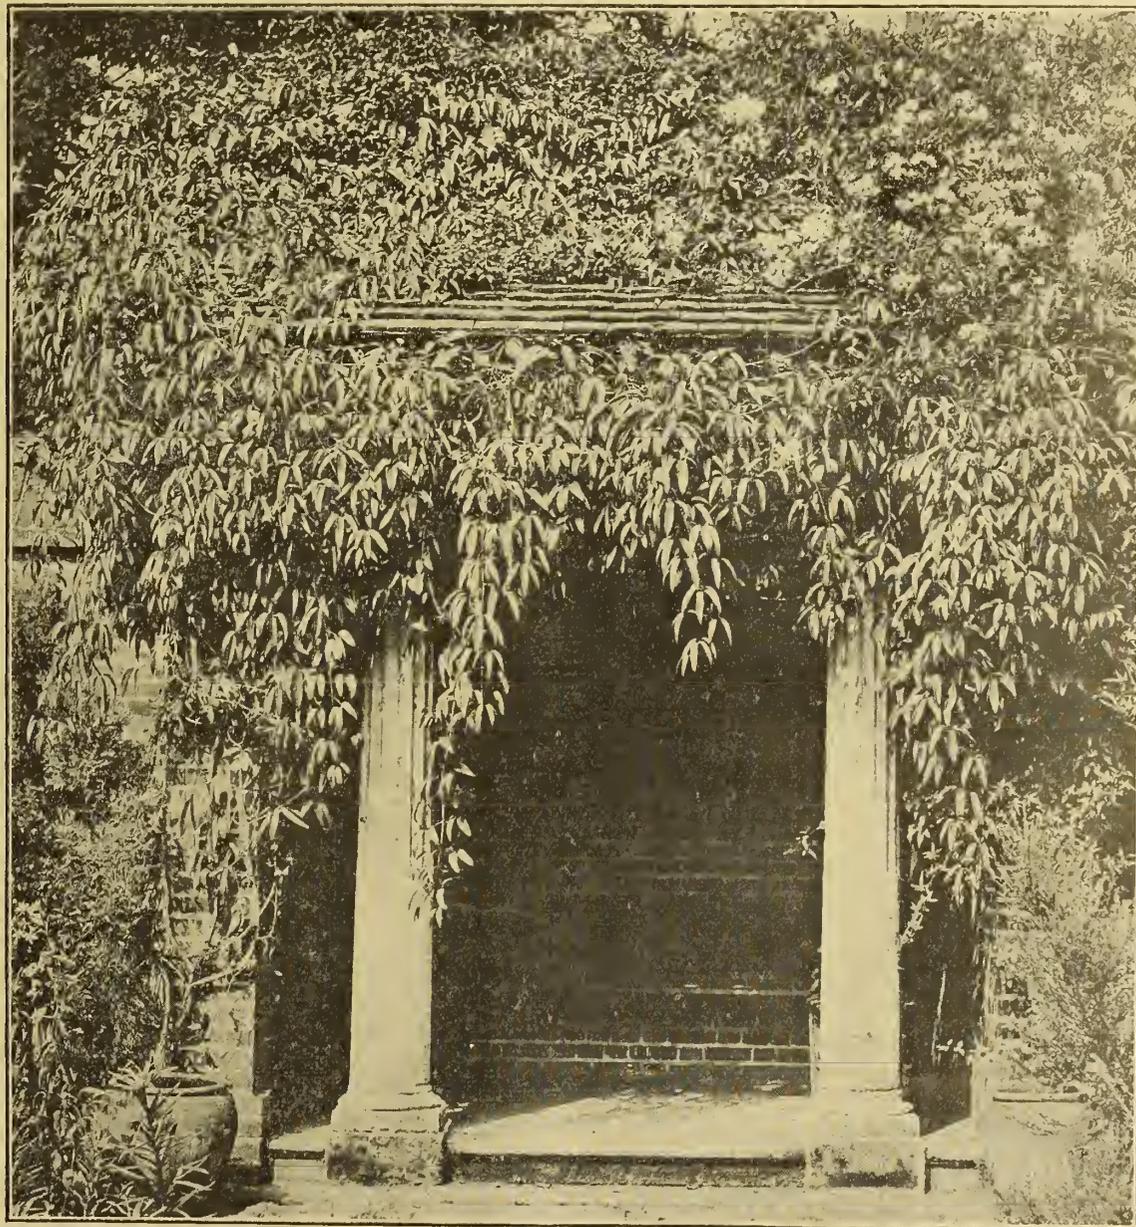

I was building a wall to help enclose a small paved garden, and the idea occurred to me that it would be a good plan to build some sort of loggia in its centre, to hold a few seats and gardening tools and provide shelter from winds and rain. Its

ing on them and the side brick pillars, holds up the rafters of the roof. Some square red tiles from a dismantled greenhouse formed the floor, and some beautifully-weathered old tiles from the stores in the yard covered in the roof, and my shelter looked venerable and picturesque from the first. Some dabs of clay planted with good forms of Houseleeks were the first plants to reach the roof, but now a tangle of a pale pink variety of Clematis montana mixed with *C. Armandii* on the left hand, and *Solanum jasminoides* on the right, covers the roof so fully that I

are followed by bunches of fruits that resemble large green spiders with downy legs.
E. A. BOWLES.

LONG-FLOWERING HARDY PLANTS.

It is in small gardens where the owner or tenant takes a real interest in his plants that one often finds at this season occasional plants, whose recognised flowering season is much earlier in the year, showing quite a nice display of bloom, and that, too, of excellent quality. The above thought was suggested by quite a nice gathering obtained to-day (October 9th)

A garden shelter at Myddelton House.

side walls were built at right angles to the main wall, brought forward some 4 feet, and projecting at the back another 3 feet, ending in front in stout brick pillars. Then I rummaged about in the stores of old stone, tiles, etc., in the various corners where the estate mason hides his odds and ends. A long and low doorstep was my first discovery. This was cut into three parts and used as may be seen in the accompanying illustration. Two pillars that had been lying in a neighbouring builder's yard were acquired at but little cost, divested of the hideous maroon paint that encrusted them, and used to support the Oak beam that, rest-

see I must mount a ladder and so arrange matters that I may see more of my old tiles and Houseleeks.

The handsome trifoliate leaves of *C. Armandii* are well seen along the front, forming the hanging fringe. This is a very fine plant to cover a large space. The evergreen leaves have a good effect at all seasons, but especially so when the young, tender, green ones of the year contrast with the deep myrtle-green shade of those of the two previous seasons. In April, and frequently again in September, it bears large bunches of white flowers, more or less tinged with green, according to the mildness of the weather, and these

from *Choisya ternata* and *Lonicera flexuosa*, although in their case the late flowering is natural and not attributable to any special treatment. On the same border, however, are sundry things also in bloom, the result of cutting away earlier in the season all old flower-stems and encouraging late growth by watering, mulching, and the like. There are, for instance, some very fine flowers on *Doronicum Harpur Crewe*, and the foliage is healthy and vigorous. A batch of medium-height *Antirrhinums* is looking nearly as well as at the first flowering. The spikes do not compare individually with the first display in quality, but the numerical strength

gives from a distance an equally good show. The habit of growth of the *Amellus* forms of Starwort gives a successional display of flowers, which, as in the case of the *Antirrhinums*, are not so large. I think this long-sustained display is preferable to thinning the growths and having all the bloom at one time, at any rate, where one is limited as to the number of plants. Although it is a little difficult with such an endless number of varieties of these Starworts to make a selection, I think one or two of the *Amellus* type should always be included. There is nothing to compare with them for size of flower, and they are so useful for cutting. A very beautiful autumn bed is obtained by associating sorts like Perry's Favourite and Framfieldi with a white Japanese Anemone. The white and lilac forms of

GALEGA will go on flowering until late in the autumn, but as the earliest blooms go off the plants must be trimmed up carefully, for if cut in a haphazard manner it will be found that innumerable little spikes in the embryo form have been taken off, which, if allowed to remain and develop, would have furnished a very pleasing display. The value of the Goat's Rue for the border was pleasingly illustrated in a recent number of GARDENING ILLUSTRATED. Two families of dwarfing habit that are very enduring if a little attention is given are *Gaillardia* and *Coreopsis*, the long-flowering season depending on keeping the plants in a healthy growing condition, remarks that also apply to some of the perennial Cornflowers; indeed, so far as our best perennial flowers are concerned the best and most enduring results are the outcome in the first place of good cultivation. This, of course, implies bastard trenching and working into the soil a plentiful supply of good manure. The difference in the condition of the plants, so far as lasting properties are concerned, is very apparent on different soils, as growers who have had to deal respectively with a light, sandy, and a heavy, rather holding soil can testify. E. B. S.

Hardwick.

OURISIA COCCINEA.

I FEAR that the position of this plant at Wisley would be no guide to me. I have known Wisley gardens from the time that the late Mr. Wilson bought the land and watched the progress of every plant there until his death. I have seen such things as *Shortia galacifolia* and *Epigaea repens* flourishing there with native vigour. I have seen *Lilium auratum* thoroughly established and multiplying, with 10 feet stems, *Primula japonica* in the finest possible condition, and *P. cashmeriana* quite naturalised and, like our own native *Priurose*, increasing from self-sown seeds. Wisley is a place by itself, and the atmospheric conditions which prevail there cannot be enjoyed in gardens generally. Possibly the extent of Heather, Furze, and Fir-trees which bounds Wisley garden on one side helps to create an atmosphere peculiarly favourable to some kinds of hardy plants. An experienced hardy plant grower once said: "You can do what you like in the way of soil, but you cannot make an atmosphere." I still think that the *Ourisia* belongs to a class of hardy plants that are much influenced by surroundings and which in some places thrive under ordinary treatment, but in a general way need special care. This is a fact which Mr. Jenkins appears to recognise in the case of the *Ourisia*. When we wish to increase a *Saxifraga*, a *Gentian*, or anything of a similar nature, we do not submit the divided portions to a preparatory coddling process, but this is exactly

what Mr. Jenkins does with the *Ourisia*. He says "they have had the protection of a somewhat shaded frame and been given humid conditions throughout, and they are pushing out roots freely." It would be wonderful if they did not. I could grow such notoriously difficult subjects as the *Shortia* and *Epigaea* in that way. It is the sort of treatment we give tender plants in the initial stages of growth.

Mr. Jenkins says this plant is not at all fastidious with him. Such being the case, why does he not plant out at once in the open ground instead of nursing the divided portions in a frame? Your correspondent's instructions in the matter of planting may be acceptable to inexperienced amateurs, but are surely superfluous in the case of those who have been working years among hardy plants. Would any man, for instance, stick the rhizomes of the little *Iris cristata* bolt upright instead of keeping them in their natural position? Mr. Jenkins says that the fact of plants failing after having pieces taken from them is puzzling, but he does not attempt to explain why they behaved in that peculiar manner. It is the only hardy plant that has acted in that way with me. Be it understood that I find no fault with Mr. Jenkins' cultural method. I shall, on the contrary, take a leaf out of his book and pot the pieces instead of planting out at once; in fact, I have already done so, but am rather late. The successful man is the one who profits by his failures and varies the treatment according to the nature of the plant he has to deal with. J. CORNILL.

SOME BRIGHT AUTUMN FLOWERS.

I do not know whether it is the scarcity of outdoor flowers as autumn advances that makes us appreciate them the more and note any that are exceptionally bright. It is certain there are several whose specially rich colour makes them very prominent features of the garden. At present (October 14th), for instance, the eye is arrested by some very bright colours among the Starworts, the rich violet of Framfieldi (*Amellus*), and in taller things the purple Mrs. S. T. Wright and the crimson Mrs. J. F. Rayner (*Novæ Angliæ*). One of the brightest flowers we have had since the beginning of the month (decidedly later than usual) has been *Rudbeckia speciosa* or *Newmani*. I always think the rich orange florets show to special advantage against the black central disc. This plant is a little difficult to establish in naturally heavy soil, but when one gets some nice clumps it makes a brave show. One does not look to outdoor flowers at this season for a clear white that will retain its purity, although it is fairly in evidence in one or two of the Japanese Anemones, both the old white and the variety known as Whirlwind. The value of anything clear and well-defined is specially noticeable at this season with all flowers. In the pink Anemones, for instance, that known as *Rose d'Automne* seems likely to be a decided acquisition. The variety of *Sedum spectabile*, again, known as *atropurpureum*, has a much more telling shade than the type. At this time, too, one gets occasional trusses of bloom on the late *Phloxes*, small in comparison to what they were earlier in the season, but with very bright flowers, because the sun has not sufficient power to scorch the petals. There are some very nice blooms on *Coquelicot* and *William Ramsay*. When choosing the later *Chrysanthemums*, both single and decorative, for outdoor work, it is advisable to select distinct colours, these being best alike for outside and for cutting. They can, however, be hardly included among hardy

border flowers, because the first frost a little sharper than ordinary is apt to spoil them. A position should be chosen that is, in a measure, naturally protected and where a little covering can be provided when required. There are not many hardy plants apart from the members of the families above mentioned that flower in autumn and whose colour is sufficiently bright to make a good display when in fair quantity. Probably two of the best are *Senecio pulcher* and *Zauschneria californica*. E. B. S.

Hardwick.

NOTES AND REPLIES.

Colchicum Decaisnei.—*Colchicum Decaisnei* is one of the most beautiful of the genus, and I consider one of the best two species, the other being *C. speciosum*. *C. Decaisnei* appears also to be interesting from a botanical point of view, for Boissier, in his "Flora Orientalis," places it in a set of three only. The perianth of the present plant measures nearly $4\frac{1}{2}$ inches in diameter, the segments are obovate, $2\frac{1}{2}$ inches long and about $\frac{3}{8}$ inch wide. The tube is about 7 inches or $7\frac{1}{2}$ inches long. The foliage of *C. Decaisnei* is finer than that of any other species in cultivation. The taller leaves reach 2 feet in height, the free blades are 1 foot to 16 inches long, and up to 5 inches broad. Some of the inner leaves are 10 inches long and 1 inch broad. The leaves of *C. Decaisnei* remain quite green while those of *C. speciosum* have become dry, but this may possibly have something to do with the position of the plants, *C. speciosum* being the more exposed.—R. IRWIN LYNCH in *Gardeners' Chronicle*.

Viola cornuta.—Few people realise what superb sheets of colour are possible by the use of this. Planted now or in the early spring, flowers will be produced from April to October if the plant is given a light, rich soil. Those who want to plant a border cheaply should try this. The border so planted looks beautiful at a distance. Plants can now also be divided and replanted. I do not think that the white variety is nearly so pretty as the blue sort.—E. T. ELLIS, *Weetwood, Ecclesall, Sheffield*.

Geranium striatum.—A great many rock plants are blooming well in my garden this year, this pretty species being one of them. It is a neat-growing species until it has been blooming for some little time, when the flowering stems get long and untidy. The flowers are of a greyish-white colour, beautifully veined with violet. A native of this country, it is of a very accommodating habit and not at all particular as to soil. It seeds pretty freely with me.—N. L.

Erigeron mucronatus.—As "N. L.," page 533, says, this needs no special care other than a well drained soil. *E. mucronatus* is a native of Australia, and reaches a height of about 1 foot. Seeds of it are offered by many firms as a hardy annual under the name of *Vittadenia triloba*, but it is nevertheless a hardy perennial.—E. T. ELLIS, *Weetwood, Ecclesall, Sheffield*.

Pyrethrum uliginosum.—Now (October 10th) this is flowering freely. Unfortunately, the wet and stormy weather has detracted from the value of this useful late-flowering plant. Its pure white blooms afford an effective contrast to the latest *Asters*, and help to make the closing of the season not the least interesting of the year.—W. McG., *Balmac*.

Linum flavum.—This is a good plant for the rock garden or border, making a bright spot when few other things are in bloom. Several of the growths have yet heads of flowers to open, and although we are nearing the beginning of November, I think they will open, because they get every bit of sun that shines.—C. T.

Tulipa retroflexa.—This has yellow flowers, with prettily formed petals, recurving in the most elegant way. It loses nothing because of its cheapness and its permanence in British gardens. It may be planted in November, and British-grown bulbs are obtainable.—S. A.

ROCK, ALPINE, BOG, FERN, AND WATER GARDENS.

CODONOPSIS.

At the present time greater interest attaches to the *Codonopsis*, by reason of several new additions from China, some of these surpassing in their quaint markings the earlier-known members of the race. A possible weak point is that of lacking complete hardiness, and in northern districts winter protection had better be afforded the roots. In other respects they are not difficult of cultivation, preferring always well-drained sandy loams and a warm and sunny exposure. So far as position is concerned it were better, because of the greater beauty of the flowers internally, that the plants be raised on moderately high shelving rocks, where the root-run is deep and good, and where complete drainage, and possibly, too, immunity from the attacks of slugs—which have a fondness for the young shoots of the plant

tudes is said to be quite hardy, and is certainly the most remarkable species of the genus.

C. OVATA (see illustration).—The flowers, two or more on a stem, are drooping, bell-shaped, pale greyish-blue in colour, with purple reticulations and orange and white base internally. The greater beauty is within the nodding bells. The plant is 18 inches or 2 feet high with small, ovate, soft, greyish and somewhat downy leaves and flowers from June onwards. Western Himalaya.

VEGETABLES.

POTATOES.

I NOTE in a daily paper that reports from several districts as to the Potato crop are satisfactory, the crop being well up to the average. It is up to the average in this neighbourhood so far as quantity is concerned, but the disease is very prevalent, quite a large percentage already bad and many slightly affected, so that it is doubt-

well. In districts where the soil is a bit holding and inclined, if damp, to hang to the tubers, it will be found advisable to dry and get them clean so as to look carefully over them before storing, otherwise a considerable percentage will later be found affected. This careful inspection is specially necessary in the case of a Potato like the Redskin flourball, the disease not being so easily perceptible. This Potato has been in cultivation many years and holds its own alike for crop and quality. Many old sorts are still well to the fore, while sorts of later introduction that came with a flourish of trumpets and sold for fabulous prices are quite forgotten. E. B. S.

Hardwick.

NOTES AND REPLIES.

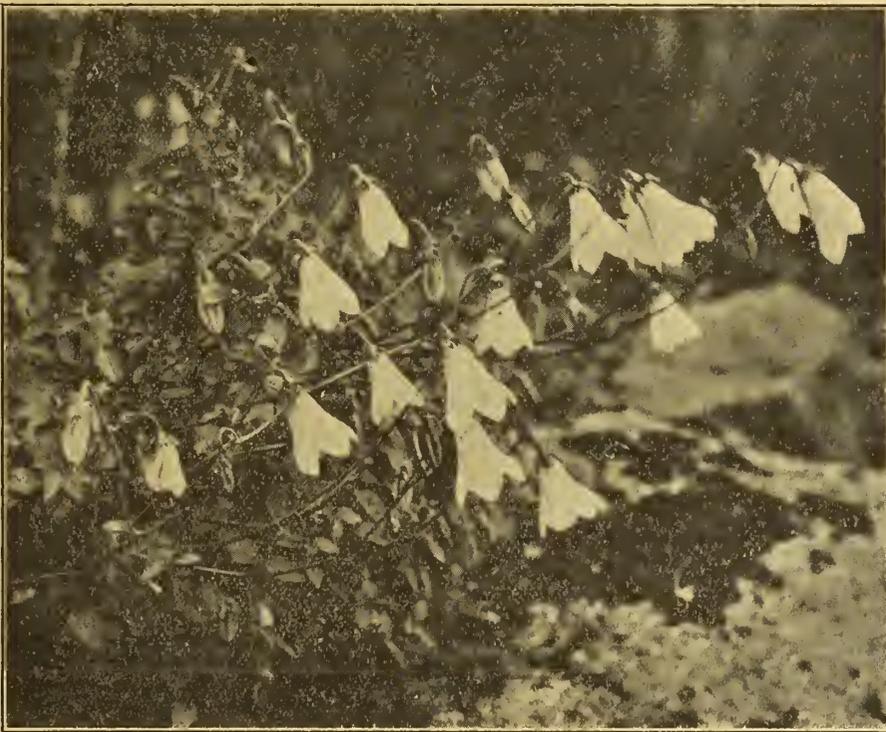

Seaweed as manure.—Seaweed may be used by itself and prove of great value, but I prefer to mix it with littery farmyard or stable manure, as it quickly reduces the strawy portion to a decayed state and renders it suitable for application to any soil. The manure and the seaweed should be turned over three times in seven weeks, at the end of which time the whole of the material will be in fine condition for digging into the soil. One load of seaweed will be sufficient to mix with three loads of littery manure. Seaweed is useful as a manure for Potatoes, Asparagus, Beans, and Peas, especially Dwarf French Beans. It is also good for hardy flowers, particularly those growing in borders of light soil. It should be dug in for vegetables during February and the early part of March.—G. G. B.

Beet.—Those who have had to do with new land during the present year and have been dissatisfied with the result of their Beet crop should remember that ground should be prepared this winter for another year. That which has been previously manured for other things, Celery for example, forms a fitting medium for this popular vegetable. Failing previously-manured ground, arrangements should now be made to well dig a piece of ground and in the second spit incorporate well-rotted manure. Many are not successful with Beet, inasmuch as they use fresh manure at the time of seed-sowing in April, which produces rank growth and forked roots quite unsuitable for the table. The round Beet seems to be more in favour every year, and for convenience of cooking there is much to be said for it. An ideal soil for it is a light loam enriched with old manure and with which salt has been incorporated just before sowing seed.—LEAHURST.

—When the time comes for storing Beet-root, it ought to be borne in mind that the leaves are rich in potash, and should not be thrown away. If dug into the quarter intended for early Potatoes, the value of these leaves is considerable. In storing Beet the roots should be carefully eased up with the fork previous to drawing, and in removing the foliage, let it be twisted off, instead of being, as is frequently the case, cut off with knife or hook, a practice which leads to bleeding.—KIRK.

Broccoli Snow's Winter White.—Few small growers of vegetables trouble about a later supply of Broccoli. They are content with cutting in September and October, but for a December crop they make no provision. One of the best of the old sorts is Snow's Winter White. If seed of this is sown in the open ground in April and the plants subsequently planted out in fairly well manured ground in an open situation one may in a mild winter look forward to good heads without the necessity of affording any protection.—WOODBASTWICK.

Potato Up-to-Date.—This maincrop Potato, which has for a few years been becoming less satisfactory, is among the worst of all in the

Part of a group of Codonopsis ovata in Friar Park Gardens.

—would, to some extent, be assured. Such a position, too, would exactly suit the trailing habit of some. The plants may be raised from seeds and from cuttings, selecting the freshly-made shoots of early spring for the latter purpose. The following are the more important:—

C. BULEYI.—A trailing species found by Mr. Forrest when plant-hunting in China. The soft, lavender-blue flowers are drooping, distinctly contracted about the middle, and openly bell-shaped at the mouth.

C. CLEMATIDEA.—A climbing or twining species of 2 feet or 3 feet high; flowers creamy-white spotted with purple and tinged with blue.

C. MELEAGRIS.—In this Chinese species the ground colour is a very pale porcelain-blue, the heavy reticulations, so striking a feature of the species, rich chocolate to purple, the base or centre of the flowers internally green. The flowers, which are solitary and of large size, are produced with some freedom in summer. This vigorous-growing alpine from high alti-

ful if they will keep any length of time. I never saw the foliage go off so quickly. It seemed to utterly collapse in a few days, and growers will fare the best who get the tubers out as quickly as possible. It is very probable that occasional spraying would have brought them through, but, in common with many districts, this practice is neglected in this neighbourhood. The cottager and allotment holder have the reputation of being very loth to try experiments, and, unfortunately, often have to suffer from lack of enterprise. Up-to-date, Redskin flourball, and King Edward are the favourite late sorts in this neighbourhood, and of the three the last-named seems the most affected. It also suffers most if left long in the ground from the attacks of underground insects, like grubs and slugs, which leads to the inference that it has a more sensitive skin than the others.

In seasons like the present, with such a pronounced failure of the late sorts, it is evident that those growers will be fortunate who rely mainly on varieties which can be lifted fairly early and also keep

south-west of Scotland this season. Not only is disease very prevalent, but the tubers are small, and in most places the proportion of ware is greater than usual.—S.W. SCOTLAND.

Tomatoes.—Fruits which are not at this date ripe may with advantage be cut and laid upon a shelf in a greenhouse, where they will ripen up well enough. If grown in pots, this practice will permit of the spent vines being thrown out in order that the house may be cleaned down in readiness for housing *Chrysanthemums* or for whatever purpose it may be desired. The crop here this year cannot be described in any other word than moderate, for while the earliest and the latest trusses set remarkably well, there was a period about the time the plants were half-grown when they could not by any means be induced to set.—W. MCG.

Potato Arran Chief.—It is claimed for this Potato that it is disease-proof. This is not quite correct, as disease is present in some which I have recently lifted. The proportion of diseased tubers is, however, extremely small. The crop is a good average one, and the tubers of excellent quality when cooked. As a main-crop Potato, Arran Chief now ranks deservedly high.—S. W. SCOTLAND.

THE WEEK'S WORK.

OPEN-AIR GARDENING.

IN BLOOM NOVEMBER 1ST.—*Choisya ternata*, *Escalonia montevidensis*, *Hardy Fuchsias*, *Solanum jasminoides*, *Hydrangea paniculata grandiflora*, *Laurustinus*, *Genista tinctoria*, *Hamelis virginica*, *Veronicas* (in variety), *Myrtle*, *Osmanthus ilicifolius*, *Ceanothus* (in variety), *Daphne Dauphini*, *Andromeda floribunda*, *Hypericums*, *Lavatera Olbia*, *Jasminum nudiflorum*, *Arbutus Unedo*, *Phygelius capensis*, *Polygonum vacciniifolium*, *Sedum spectabile*, *Pyrethrum uliginosum*, *Helianthus* (in variety), *Pampas Grasses* (in variety), *Lobelia cardinalis*, *Antirrhinums*, *Pentstemons* (in variety), *Gazania splendens*, *Tufted Pansies* (in variety), *East Lothian Stocks*, *Crocus speciosus*, *Sternbergia lutea*, *Hardy Cyclamens*, *Amaryllis Belladonna*, *Enocheras* (in variety), *Polygala Chamæbuxus lutea*, *P. C. purpurea*, *Gypsophila muralis*, *Parochetus communis*, *Linarias*, *Verbena venosa*, *Mertensia echioides*, *Omphalodes cappadocica*, *Valerian*, *Orobis Vicia*, *Correa magnifica*, *Aubrietias*, *Androsace lanuginosa*, *Arabis*, *Lithospermum prostratum Heavenly Blue*, *Mexican Poppy*, *Armeria Lauchcana rosca*, *Dwarf Campanulas*, *Nepeta Mussini*, *Iris stylosa*, *Salvia Gregoi*, *Anchusa Opal*, *Michaelmas Daisies* (in variety), *China*, *Polyantha*, and *Climbing Roses*, *Clematis* (in variety), *Ericas*, *Polyanthus*, *Violets* (in variety).

THE WEEK'S WORK.—The frost having destroyed the foliage of Dahlias and Begonias, these have been lifted and stored for the winter. The stems of Dahlias are cut off to less than 1 foot of the roots and the tubers stored in a frost-proof shed. The corms of Begonias were cleaned and stored in boxes of dry sand. Cannas have also been lifted, cleaned, and stored in boxes of leaf-soil. The tender plants, which have hitherto been in cold frames, have been removed to vinerias in which the Vines are at present resting and where a little fire heat is used occasionally to expel damp. *Calceolaria*, *Pentstemon*, and *Viola* cuttings in unheated frames merely require protection from frost, and plenty of ventilation is afforded during favourable weather. Lily of the Valley needs lifting every two or three years to prevent the crowns becoming unduly crowded, as when this happens the flower-spikes soon deteriorate. The present is a suitable time for the work. It is a good plan to have several beds in which the plants are of different ages, so that it only becomes necessary to lift a part of the stock at a time, as the flowers are not usually so fine the first year after replanting. The crowns should be carefully divided and graded, planting the larger ones by themselves, as they may be depended upon to flower. When replanting the crowns a fresh position is advisable, but if this cannot be afforded, the soil in the old bed should be deeply worked and plenty of thoroughly decayed manure incorporated with it. In order that the flowers may be gathered conveniently, the beds should not be more

than 6 feet in width, allowing a space of about 15 inches between the beds. If the situation is cold and damp it is advisable to raise the beds a few inches above the level of the alleys. Established beds should be cleaned and top-dressed with manure. During severe weather some of the more tender plants will require slight protection. To what extent protection has to be carried out depends to a great extent on the district in which the garden is situated. To cover a plant unnecessarily is almost as bad as insufficiently protecting it, for when the protection is removed the tender growth is very susceptible to late spring frosts. If evergreen plants have to be covered, the covering should be removed on all favourable occasions to admit air and light. Tender shrubs of moderate size may be protected by placing a few inches of Spruce branches around them, inserting them firmly in the ground.

F. W. GALLOP.

Lilford Hall Gardens.

SOUTHERN COUNTIES.

Early vinery.—The leaves having fallen the Vines should be pruned without further delay; when, if necessary, the cleaning of the rods and afterwards the structure may be held over until employment for some of the more experienced outside hands can be found in wet weather. If the wood is well ripened and the Vines in a satisfactory condition, the laterals may be cut back to one bud; but if the buds are not so plump as could be desired, then it is advisable to cut back to just above the second bud. When the Vines are being cleaned remove the loose bark only, and follow this up by scrubbing the rods, taking care that the buds are not injured. Dressing the rods afterwards with Gishurst compound or some other approved insecticide will suffice when nothing beyond a recent outbreak of red-spider has to be contended with; but if infested with mealy-bug, more stringent measures are necessary. Not only must the cleaning of the rods be more carefully carried out, but their subsequent dressing must be something of a more searching nature, such as a mixture of coal tar and clay, in applying which care must be taken that it does not come into contact with the buds. The soil of the border, after the woodwork, glass, and brickwork have been thoroughly cleaned, must be removed to a depth of 2 inches or 3 inches, and fresh loam, to which the usual additions in the shape of artificial manure, wood ashes, and lime rubbish have been made, added. Until the time arrives for starting, the house should be kept quite cool.

Late Grapes being now quite ripe, the house should be cooled down, but the temperature must at the same time not be allowed to fall too low, and the atmosphere should be kept perfectly dry, otherwise the Grapes, particularly the thin skinned varieties, will spot and decay. To obviate both evils, the keeping of the hot-water pipes just warm enough to cause a free circulation of air and ample ventilation in fine weather are necessary. Late Muscats now thoroughly ripe need similar treatment, and, if anything, a trifle more fire heat may be indulged in, especially when chilly or foggy weather has to be encountered. If the border is in a satisfactory condition as regards moisture, covering the surface with about 3 inches in depth of dry litter will prevent damp rising.

Asparagus.—The tops having turned yellow should now be cut down to about 4 inches above ground level, taking care when doing so that the berries do not drop on the surface of the beds and cause future trouble by crowding the legitimate occupants and eventually killing them. After lightly hoeing the surface and raking off a couple of inches of the loose soil, apply a good dressing of rich manure. Beyond spreading the manure, nothing further is needed until spring. Beds that are to be broken up for forcing need not be manured.

Forcing Asparagus.—Preparations for forcing Asparagus from now onwards should be pushed forward. A heated pit, where such can be spared, saves much time and labour, but excellent produce can be had with the aid of a fermenting bed of stable-litter and leaves. As the latter will soon be available in quan-

tity, a bed made up of one-third fresh stable-manure and two-thirds leaves, large enough to accommodate one or two frames, will, if the materials are thrown together and turned a few times beforehand, generate quite sufficient heat for the forcing of Asparagus. When the bed is ready the roots may be lifted and placed on the surface quite close together after spreading old potting soil over the latter about 3 inches in depth. The crowns should be covered with the same kind of material. The temperature of the frames should be kept from 55 degs. to 58 degs. In cold weather it is necessary to cover the sashes with mats. When mild, admit air when possible to prevent the produce from becoming drawn.

Chicory.—This should be lifted and stored, or the roots may instead be lifted and stood in an upright position close together in a trench taken out sufficiently deep so that from 3 inches to 4 inches of soil will rest over the crowns when covered up. Salsafy and *Scorzonera* should also be lifted and stored, placing a layer of fine cinder ashes or sand between the roots.

Pot Strawberries.—If frames can be spared, the plants are better if now placed therein than allowed to remain any longer in the open, as the sashes can then be drawn over them as a protection when heavy rain or snow appears imminent. On all other occasions—during sharp frost excepted—they may have abundant ventilation. Failing the above, the only alternative is to remove them to a Peach or orchard-house, standing the pots where the plants will receive all the light obtainable. Free the plants of dead leaves, weeds, and Moss before taking them in, and wash the pots, which will save having to do so when the time arrives for starting later on.

Alterations.—The present is a good time to carry out any necessary alterations or improvements, either in the kitchen garden or pleasure grounds. It is now the rule to devote a portion of the kitchen garden to flower culture, this generally being confined to the borders on either side of the principal walks. Two such borders, which are of considerable length, the greater part of which has already a backing of Rambler Roses, are now being cleared, and, after being dug to rid the soil of wild *Convolvulus*, old roots, etc., it will be manured, re-dug, and then planted with Hybrid Perpetuals, Hybrid Chinas, Teas, and their hybrids. The Ramblers will be overhauled, thinned, and relieved of old wood, and retied to the trellis constructed of Larch poles. The choicest varieties of the Ramblers will be planted to complete the arrangement. The Tea and other Roses will be planted in not less than twelve of each variety. A border will also be provided for the growing of the best of the Michaelmas Daisies, another for early-flowering *Chrysanthemums*, and the same for *Antirrhinums*. A long border situated outside the kitchen garden, and having a brick wall at the back partly clothed with old fruit-trees, will be cleared, and the border planted with choice herbaceous subjects, and the wall with *Clematises*, *Roses*, *Jessamines*, *Loniceras*, *Choisya ternata*, *Ceanothus* in variety, etc. Any alterations required with regard to widening or altering the course of footpaths, redraining and gravelling of the same may be undertaken as opportunities offer. The same remarks also apply to the taking up, levelling, and relaying of lawns, and the formation of croquet and tennis courts. New flower beds can also be formed if additions are desired, or a new scheme carried out. A. W.

MIDLAND COUNTIES.

Fruit-trees on walls.—The pruning and training of fruit-trees on walls should be pushed forward, so that as much as possible of the work may be completed before the winter. It is advisable to place planks on the border, as then not only will the work be done more comfortably, but trampling of the surface of the border will be prevented. In our case, Morello Cherries, Peach, and Nectarine trees were attended to soon after the fruits were gathered, and very little pruning remains to be done to these trees. In all cases it is best to do the pruning before the trees are removed from the wall, as the operator cau-

then see what shoots can be spared and what are necessary to furnish the wall space. Neglected Morello Cherry-trees can be renovated in a much shorter time than is necessary in the case of most fruit-trees. It is necessary to train in almost all the healthy young wood and remove worthless shoots, but the cutting out of much growth at one time is not to be recommended. The pruning of the Sweet Cherry is entirely different from that practised in the case of Morellos, for the Sweet Cherry fruits best on spurs. Pruning and thinning the trees in summer result in spur formation, and trees that have been properly summer-pruned require but little attention now. On no account should large branches be cut out or the knife used unnecessarily, for this is a frequent cause of gumming. After the trees are pruned they should be thoroughly cleaned before they are fastened to the wall.

Plant-houses.—The main batch of Chrysanthemums will soon be in full beauty, and every effort must be made to keep the blooms in good condition as long as possible. Ventilate the house with care, and maintain a little heat in the hot-water pipes to dispel moisture. Leave the top ventilators open a little at night and maintain a minimum atmospheric temperature of 50 degs. Remove any decaying leaves as soon as they are seen, and keep the house clean. As early varieties pass out of flower throw out all those plants not required for stock, retaining only the best for this purpose. Cut down these selected plants and place them in a frame near to the glass, that the suckers may become sturdy and robust, remembering that strong cuttings are in every way desirable. The latest varieties should be kept as cool as possible without allowing frost to reach them, but when the buds begin to show colour a warmer atmosphere will tend to the better development of the blooms. As all the light it is possible to get into plant-houses is now necessary, climbing plants should be carefully overhauled, thinning out all superfluous growths and cutting back the old flowering shoots. The earliest batch of Carnation cuttings which have been rooted in sand are now ready for potting into thumb pots, using a sandy compost. After potting, the plants are placed near to the roof glass in a house where an atmospheric temperature of 55 degs. to 60 degs. is maintained. Nine degrees of frost registered in this district on the nights of October 20th and October 21st have put an end to all the more tender vegetables, such as Marrows and Beans. Now that the outside

French Beans are past the value of those which were sown late in slightly heated pits will be appreciated. Provided the plants are not over-forced, these will continue in bearing for some time to come. A little air is admitted whenever possible, maintaining a temperature of 50 degs. to 55 degs.; and when water is needed at the roots, it is given in a tepid state.

Cauliflowers have suffered very little so far from the frost, but the plants need to be examined at least twice a week, and all those of sufficient size lifted and placed under cover. Any heads which are now formed are well screened from frost by placing spare leaves upon them and tying up the tall ones in such a manner that they will shield the centre. Spring Cabbages have been moulded up right up to the leaves. This treatment does much to ensure the plants passing through a severe winter. The growth of

Globe Artichokes has been cut down nearly to the ground and a quantity of cinder ashes heaped about the base as a protection to the stocks. Before the ashes are applied the soil is loosened with a fork in order that water from heavy rains may pass easily away. In the event of severe weather, straw or litter will be applied as a further protection. The blanching of

Leeks should be completed as soon as possible. If planted in trenches, the soil should be banked up to the point at which the foliage commences. Those that were blanched early will now be lifted and stored in sand in a sheltered position, leaving the foliage exposed to the weather. A few of the earliest crowns of Seakale have been lifted and laid on top of the ground to prepare them for forcing.

Rhubarb roots that were lifted and exposed as advised in previous notes are now ready

to be placed in the Mushroom-house. Another batch of roots has been lifted and exposed to the air to form a succession.

Asparagus is one of the easiest vegetables to force. If strong, well-matured crowns are available a start may be made at once in a brick pit where a little heat can be applied in frosty weather. A moderate bottom-heat is necessary. The bed of the pit should be removed to the depth of 4 feet and replaced by a quantity of fresh leaves, which should be collected and placed together for fermentation previous to use. When the leaves are placed in the pit they should be trodden firmly until the surface of the bed is within 18 inches of the roof-glass. A covering of thoroughly decayed manure should then be placed over the surface of the bed, covering this lightly with sifted leaf-soil, so that the Asparagus roots may not come into contact with the manure until growth commences. Exercise care in lifting the roots and place them in the pit as quickly as possible. They may be arranged quite closely together and covered lightly with fine sifted soil, which should be watered in amongst the roots with tepid water. After a few days the young shoots will begin to appear, and at this stage a covering of fine sifted leaf-soil should be placed over the surface to a depth of 4 inches, after which the shoots will grow more quickly. The temperature of the bed must not exceed 80 degs. or the roots will be scalded.

F. W. GALLOP.

SCOTLAND.

Asparagus beds.—When the stems are thoroughly ripened no good purpose is served by allowing them to remain. In cutting them over, it is sometimes customary to use a hook or the scythe. This is deprecated, because the force used is, as observation will prove, very apt to injure the embryo crowns. It is better, even at the expenditure of more time, to use the knife—and a sharp one at that—to cut over the stems. These can be buried if trenching is going on—a way of disposing of these and similar things in a very convenient manner. After the stems are removed the surface of the beds ought to be thoroughly freed of weeds, either by hoeing and raking or by hand-picking. Some consider it necessary to cover the stools with manure, which is allowed to lie on them over the winter. I think this a mistake; but, naturally, something depends on soil and climate. In very light, porous soils, a covering of manure may be necessary; but I think that in ordinary conditions the winter manuring of Asparagus is a fallacy. Favoured by a period of highly suitable weather, this annual cleaning up in connection with the Asparagus beds was carried out in the course of the week.

Artichokes.—The treatment of Artichokes during winter is different from that accorded to Asparagus. Naturally more susceptible to hard frosts, it is necessary to afford the former a fairly good mulch of half-decayed manure or of Bracken or litter of a similar character. I have seen the foliage tied up in bundles round the crowns of the plants at this time of the year, but, as these leaves are affected by frost, I could never see wherein the benefit lay, and I prefer to mulch somewhat freely before the time when severe frost may be expected. The plants yield, even at this date, an occasional head, and have done well during the season.

Cabbages.—During the week a finish has been made with the planting of Cabbages for the present year. The variety used was Flower of Spring, which will turn in conveniently after the previous plantings. These have made very fair progress despite the erratic weather, and, taking advantage of the dry time, the soil between the lines, having previously been dressed with soot, was hoed up rather deeply. This will complete the work among these Cabbages until growth again begins in the spring.

Beet.—The crop has been very satisfactory, and in the course of the week the roots have been lifted and stored. In lifting Beet care is necessary, for if the skin be broken bleeding will ensue, and both the colour and the flavour be spoiled. In lifting, let the roots in each line be eased out by means of a digging

fork, and instead of cutting off the leaves with the knife, they ought to be twisted off. It is worth mentioning that, chemically, the leaves of Beet are rich in potash, and should, therefore, be dug in at once instead of being taken to the rot-heap. Beet may be successfully wintered under the same conditions as Potatoes; it is as well, however, to place the roots in layers, with a good allowance of sand between each layer. In the absence of sand, finely-screened, perfectly dry soil makes a good substitute.

Parsnips.—Strictly speaking, it is not needful to lift and store Parsnips; but in my own case it is more convenient to do so, and they keep quite as well when stored as they do when left in the ground. They are treated exactly in the manner described above with reference to Beet. Owing in a great measure, no doubt, to the rather wet season, the roots of Parsnips are larger than usual—larger, indeed, than is necessary. A medium-sized root will always be of better flavour than a larger and coarser one; and it is worthy of note that medium-sized—even smallish—Parsnips are preferred in the kitchen.

Winter vegetables generally received a look round in the course of the week. Brussels Sprouts are firming up well, and Savoys and Curly Greens still continue to grow. In the case of Sprouts, it is advisable that a few of the bottom leaves be removed in order that a free circulation of air may be maintained and as much light as possible admitted. Leeks and Celery are yet growing, but the increasing cold at night will soon give these things a check.

Parsley in frames.—On all suitable occasions let the ventilation be free by night and day, and care must be taken that sufficient moisture is given. Emphasis is laid on "sufficient," for if too much water is applied the plants will rot, while, on the other hand, if moisture be given too sparingly the leaves will, most certainly, turn yellow.

Digging and trenching.—During the week a good start was made with the turning up of vacant quarters. It always pays to get along with this important work as quickly as is consistent with good workmanship. Good spademen are scarce owing to circumstances, so that it will not be possible to undertake quite so much trenching as usual, but if honest digging is done no great difference will be noticed in respect of the crops carried by breaks which have been trenched a season or two ago. Let manure be given with a free hand where it can be obtained. We hear much about economy in these days, but it is false economy to starve vegetable ground. Two quarters—those intended for Peas and for Onions—at whatever expenditure of time, will be trenched. Quarters trenched last season may, with digging deeply, be relied upon to grow Potatoes, Broad Beans, and Cauliflowers quite satisfactorily.

Cleaning up.—Some spare time was devoted to clearing off the spent haulm of Sweet Peas, exhausted Vegetable Marrow plants, the straw of Peas and of Broad Beans. All that will burn goes to the fire heap, the residue to the rot heap.

Under glass.—The fine weather having been used for pushing on the work out-of-doors, the work under glass was limited to routine. Watering, as is needed, is attended to every morning—the best time always to do such work. In order to dry up superfluous moisture after watering, the heat is run briskly through the pipes, after which the fire is banked up. Free ventilation is, of course, given on all suitable days. Among plants in pots, Nerines, now passed out of bloom, must yet be regularly watered. It is fatal to success in the case of these fine bulbous plants if their season of growth—a long one—is unduly curtailed by affording them too limited supplies of water. Keep them yet in the same temperature in which they bloomed, and a little soot-water—rather weak—will keep the foliage in good health. There is not yet need of more than very moderate fires. Stove round about 65 degs., greenhouses 54 degs., cool-houses 48 degs. to 50 degs., all at night.

NOTES OF THE WEEK.

Crocus speciosus.—This certainly deserves the favourable notice you give it at page 555, but I find *Crocus medius* at this season even more effective, with its rich purple colouring and scarlet anthers. With me it is also more free-flowering than *C. speciosus*.—D., Orchardton Castle, Douglas, N.B.

Rose Comtesse de Cayla in the house.—This China Rose as a cut flower is of great value, the colour superb day or night. It grows well from cuttings, and, indeed, in the usual nursery way. I like it best in a bronze pot if there be one at hand. Glasses are not nearly so good as opaque vessels. In the open air it is never out of flower in summer or autumn.—W.

Crocus speciosus Artabir.—Of the forms of *Crocus speciosus* this is one of the best. It has large, light blue blooms, and makes a nice variety to the typical *C. speciosus*, which has deeper-coloured flowers, and to *C. s. Aitchisonii*, which it surpasses in size. It was sent out a few years ago by M. Van Tubergen, and has as yet only found its way into a limited number of British gardens.—S. ARNOTT.

Verbena venosa poisonous.—Seeing in GARDENING ILLUSTRATED this week an answer to an enquiry about *Verbena venosa*, I think your correspondent should be warned that it is a highly poisonous plant. Some years ago a plant was given to me, and I planted and trained it myself, instead of leaving it to the gardener. The result was, I had blood-poisoning in both hands and wrists, which was very difficult to cure. Our doctor, who is a very good botanist, considered it a very dangerous plant to handle.—K. M.

Berberis Thunbergi.—Among the many varieties of *Berberis* now in cultivation none can compare with the above in the exceeding brilliancy of its foliage in autumn, and for which good attribute the species merits attention. To a brilliant colour effect must be added a neatness of habit removing it from the common-place and rendering it welcome for grouping. The rich colour is assumed early in autumn, and, while most pronounced where given full exposure, is, perhaps, brightest where the plant is grown in warm, well-drained soils.

Cutting off the stems of hardy plants.—Are we not, most of us, in too great a hurry to cut over the ripe and ripening stems of hardy plants? During the week I have been noticing the many varied autumn tints which they provide. *Dielytra*

spectabilis has turned to a beautiful pale golden-yellow, the *Loosestrife* (*Lythrum roseum superbum*) equals in colour the bronzing *Azalea* leaves, the ripening stems of *Asters* are not unattractive, nor are their downy seeds, although these ought to be removed. *Epimediums*, *Helianthus*, *Thalictrums*, *Lysimachias*—only to name a few—also take on very fine colouring, and in an open season, such as this, so far, has been, certainly add much to the interest of the hardy flower borders.—KIRK.

Crocus aërius.—This species is closely related to *C. chrysanthus*, but running into wonderfully rich shades of blue and purple, with almost crimson markings on the outer segments. It is not quite so robust here as *C. chrysanthus*, though, I believe, both grow together on the Bithynian Olympus. Mr. Smith, of Newry, used to have the finest stock of *C. aërius*, but nowhere can you get it cheaply, as it is rare as well as beautiful, and with me it increases so slowly that even by raising seedlings I have very little of the good forms.—E. A. B.

Carpenteria californica.—Although our soil and aspect are very suitable for most of the Californian half-hardy plants I cannot induce *Carpenteria* to bloom. The shrub is growing at the foot of a west wall, in well-drained soil, and is perfectly healthy. It is now about 3 feet high, and this year it has sent up a strong shoot some 2 feet in length from the base. But it has shown no sign of blooming, and this is its third year. Judging from an acquaintance with this subject in its own country, our conditions ought to meet its requirements. Does it demand any special treatment here to encourage it to bloom?—A. T. J., N. Wales.

A fine hardy Crinum (*C. Yemense*).—This has proved the finest of all hardy *Crinums*, a splendid plant in every respect. The Kew hand list relegates it to the minor position of a varietal form of *C. latifolium*, to which I may say it has no resemblance, and is, in fact, in every respect superior. It has been for about ten years in its present position, and continues to increase and flourish. The leaves are strong and upright, dark shining green, not easily damaged. The scapes are numerous, very sturdy and erect, and able to withstand severe storms, each carrying from thirty to fifty flowers, which are of good substance, pure white when fully open, and there are frequently, when the weather is fine, about a dozen flowers open at the same time.—F. W. Moore in *Irish Gardening*.

Our wild Clematis as a stock.—Mr. Cornhill vexed me by his learned consideration as to how this behaved on chalky soils or others, and this with regard to its influence as a stock. It is of no value whatever as a stock, its use having done infinite harm to British gardens, killing thousands of the loveliest plants known. I passed it lately on the hills 30 feet or more high, a northern *Liana* on which a desperate man might hang himself. In Wiltshire it is called *Devil's Guts*, no doubt from the difficulty of getting rid of it. It may well be left to find its own way.—W.

Rose Trier.—I am writing this note at the end of October, and have just cut some lovely sprays of from fifteen to twenty blooms of this Rose. The flowers are creamy-white, semi-double, with golden anthers, and have the fragrance of a wild Rose. It is the most dainty cluster Rose I know, and, unlike the other *Ramblers*, it not only flowers freely in July and August, but gives a few clusters until cut off by frost. It has not the rampant growth of *Dorothy Perkins*, being, if I may use the expression, more "staid" in growth and charming when seen at its best towards the end of July.—LEAHURST.

Cheiranthus linifolius was sown in February and planted out early in June in good sandy loam and a sunny position. A few flowers opened on most of the plants about the middle of August and are still as they were. I am told my plants are much too close together—18 inches apart is the right thing. This, however, does not seem to be the reason why they do not flower freely. Two plants in the same border have not flowered at all, though they are a long way from the others. Can any of your correspondents tell me how to make this very pretty *Cheiranthus* flower freely?—E. C. Buxton, *Coed Derw, Bettws-y-Coed*.

Yucca Whipplei.—In a recent number mention was made of *Yucca Whipplei*, a species growing wild throughout S. California. There are at least three forms of *Y. Whipplei* characterised chiefly by size, vigour, and habitat. One, the smallest, has a flower-spike from 5 feet to 8 feet high. It frequents the low foothills on the hot, dry, rocky sides of which it flourishes. Another grows in the valleys in sand or sandy loam, and throws an immense spike 10 feet to 12 feet or more in height, with, I should say, 5,000 to 8,000 large creamy-white, fragrant bells, each 2 inches or more in diameter. The third form is similar in appearance and vigour, but grows at between 5,000 feet and 6,000 feet altitude,

where much snow falls and frosts are frequent. This form should prove perfectly hardy in England. Of course, the dampness may be detrimental to it.—J. HARRY JOHNSON, 5,475, Franklin Avenue, Los Angeles, California, U.S.A.

Loss of colour this year.—It is the worst year for colour of the leaf that many remember. The cool days and warm October nights seem to have kept the plants growing instead of putting on their usual autumnal dress. The only tree—an exception to the rule this year is the Red Oak (*Quercus rubra*). Not so showy as the scarlet Oak, it is a noble tree, its soft red and brown colours very welcome to me. The leaves of our native Oaks beside it are quite green. The Liquidambar is not in its fine colour yet, and the snowy Mespilus (*Amelanchier*) hesitating. The Norway Maple is doing its duty, but not so bright as usual. The noble Japanese Vines that have made the garden glorious with colour are not nearly so good, though certainly giving the finest shades of any plants. The French Teinturier, of which I grow several forms, is not nearly so fine in colour as in other years.—W.

Begonia Mrs. J. A. Petersen.—Since the now universally-grown Begonia Gloire de Lorraine was raised, about twenty-four years ago, several allied forms have been put into cultivation. One of the newest arrivals, and a desirable kind, too, is Mrs. J. A. Petersen, raised in the United States. In this the flowers are much richer in colour than those of the type, while the foliage is of a pleasing reddish-bronze shade. From its richness of colouring it is a welcome addition to Begonias of the Lorraine type. Though these Begonias were at first considered to be somewhat particular in their cultural requirements they do not now present any difficulty in this respect. The main point is to give them a period of rest after flowering, then partially cut them back and introduce into heat. This will lead to the production, near the base of the plant, of sturdy shoots which, if taken off when about a couple of inches long, will soon root. Cuttings taken from the points of the shoots will never form bushy specimens.

The Macartney Rose.—Mr. Edward H. Woodall, writing in the *Garden*, says:—

"I am glad to know that Rosa bracteata grows with such vigour on a wall in the warmer parts of England, for it is charming in autumn when its bright, glossy foliage is set off by the pure white petals and golden stamens of its sweet-scented flowers that succeed one another for many weeks on a warm wall. My principal motive, however, in writing this note is to remind Rose-lovers of its peculiar merit as a stock on which to bud Roses that seem refractory. There certainly are some Roses that grow better and colour far more brilliantly on this stock than on any other, and it is well worth a trial when you have a good Rose that refuses to do well with you on any ordinary stock. Quite ten years ago I budded that beautiful but most capricious Rose Georges Schwartz on R. bracteata, and now the bush is stronger and more vigorous than ever, while on any other stock it dwindles and dies out after two or three years. Another Rose that is quite marvellous in growth and colouring on this stock is General Gallieni; its size and brilliance are quite abnormal, especially in spring, when the first blooms on any other stock are defective in colour and shape. So, though it may not be a stock for the nurseryman, it is well worth a trial by the amateur."

VEGETABLES.

POTATOES IN 1916.

THAT Potatoes are very dear is too well known in households generally. That they will become dearer still is the opinion of those best qualified to form an accurate opinion. What the maximum price per ton will be before early crops come no one can say, but anything between £12 and £20 per ton is predicted. At the present time £10 per ton is the price in the London markets. Everything has been against the Potato this year. In the first place, many of the larger growers were either unable or unwilling to plant the usual area, unable by reason of shortage of labour, unwilling because Wheat, making the price it does, they thought it would pay as well, or better, than Potatoes, with much less expense, for half-a-dozen acres of Wheat can be drilled in in less time than it takes to plant one acre of Potatoes. Therefore, to begin with, there was a diminished acreage; then came the shortage and corresponding high prices in May and June, which caused growers to dig large breadths which would otherwise have been allowed to run the usual course. One grower said that these early crops, at four tons to the acre, would pay him better than nine tons in the ordinary way, and, of course, the land was clear for another crop. It will, therefore, be seen that the acreage of keeping Potatoes has been considerably diminished, and this fact alone would tend to stiffen prices. Just when rain was badly needed there was, in most districts, a spell of heat and drought, which, in a measure, paralysed development, and when the rain did come it fell on enfeebled plants, and the temperature was abnormally low for the time of year. The average yield appears to vary considerably, some districts being very badly hit by disease, the favoured spots where the yield is up to the average being few and far between. The accounts from Scotland are dismal in the extreme. Not only was disease rampant, but in some places frost cut off the haulm, so that the yield in some cases is not more than three tons to the acre. It is the same in Ireland, the yield being estimated at from 30 to 50 per cent. below average, and it is reported that in view of this shortage the Government will, in all probability, forbid the export of Potatoes from there.

Out of these facts arises the problem of where seed is to come from for the southern parts of England. A grower here says that he can get no quotations for Scotch seed, there is none to be offered, and I should hesitate to use seed from plants that were subjected to such enfeebling conditions. Fortunately, Yorkshire is a bright spot in a dismal record, and it is to the county of broad acres that we in the southern counties must turn for salvation. Shropshire and Cheshire have a fairly clean record. We value Scotch seed on account of the superior energy which a bracing climate imparts, but this vigour, having been eliminated by abnormal climatal conditions, we must rely on those localities which have been sufficiently favoured to admit of a higher degree of maturation. This is really a very important matter, and should receive consideration from Potato growers generally, for no one can hope for a full crop from imperfect seed.

Those who cater for the public in this matter will have to use judgment in the selection of seed, and should take every possible means to ensure a supply from localities where growth has been normal. I am in the fortunate position of being able to use my own seed this year, having

procured Scotch seed last season. My crop was uneven—good, bad, and medium—so I selected seed tubers from the best plants, and this I would advise your readers who may be similarly circumstanced to do. There is no appreciable difference the second year in the cropping powers of Potatoes from the North, but it must not be repeated or there will be failure more or less pronounced. Wherever possible, Potatoes should be stored under cover. There will, I feel sure, be heavy losses in the clamps. The weather could not be worse for lifting; much of the crop will be stored wet, and a diseased tuber here and there will cause a lot of decay later on.

BYFLEET.

FORCING RHUBARB AND SEAKALE.

WHERE the Apple crop has been a short one forced Rhubarb can be used to make up the deficiency. The forcing may be conducted either where the crowns are grown, or the roots may be lifted and placed at the warmest end of a Mushroom-house. In the latter instance it is a good plan to expose the crowns to the weather for a week or two after lifting before placing them in warmth. This causes them to start into growth much more quickly than if taken in as soon as lifted. Regarding the other method of forcing, more time is required, but there is no necessity to lift the roots. Failing a supply of pots sold for the purpose, old cement and flour barrels answer equally as well. Warmth is supplied by placing a mixture of tree-leaves and stable-manure, in which the former largely predominate, round whatever is employed for placing over the crowns. Covers must be provided, for the two-fold purpose of releasing steam when the fermenting material first beats up, and afterwards for enclosing warmth. When growth begins to push up, the covers are then best tilted, and whatever protection is needed can be afforded by placing some loose litter lightly over them. It saves much time and trouble if the heating material is mixed, thrown together in a heap, and turned three or four times beforehand. A heap should always be in reserve for renovating. Much that has been said about Rhubarb is applicable to the forcing of Seakale. If the forcing is to be conducted in a Mushroom-house the crowns, after being planted and watered, should be covered with clean tree-leaves to a depth of 9 inches, which causes the Kale, as it develops, to grow close and compact. Very good Seakale can also be grown in a deep frame placed over a well-made hotbed, provided daylight is effectually excluded.

K. P. S.

Onions decaying.—Can you tell me why my Onions are like this one? They are autumn-sown, were transplanted in February, and taken up in July, dried in the sun, and left spread out.—RUSHFORD.

[Judging by the appearance of the Onion you send, we should say that the bulbs have either been kept in too warm a place, or they were not properly matured when stored.]

Brussels Sprouts failing.—Nearly all my Brussels Sprouts have no Sprouts formed or forming, though they are big, strong plants.—RUSHFORD.

[With regard to the Brussels Sprouts, it may be that a sufficient length of time has not elapsed between the time of planting and now for Sprouts to have formed. If they do not eventually develop you may then know that the plants are at fault. We should, however, think they will yet form Sprouts.]

Tomatoes ripening unevenly.—I am sending you two Tomato fruits grown by a friend of mine, who is much vexed by the trouble they show—uneven ripening, hard green

patches on, more especially, the undersides of the fruits. This is a fairly common trouble, and most of us have our own theories as to the cause. My friend is a most careful and capable grower. Of late years his Tomatoes have been much attacked by Cladosporium. Would this be a possible cause of the defects in the fruit, do you think?—A. CAMPBELL.

[The general opinion regarding the uneven ripening of Tomatoes and the presence of hard green patches on the fruits is that it is due to a deficiency of potash in the soil. We also share in this opinion, and during a long experience have found that when potash is freely supplied to the soil in some form or other the fruits are never so affected and always

PLANTS AND FLOWERS.

OUTDOOR PLANTS.

THE NOBLER FUCHSIAS IN THE FLOWER GARDEN.

LONG struck by the beauty of some of the wild Fuchsias, I began to use them in the flower garden, and in this cold year they have done and looked well, both in flower and leaf. The kinds used are corymbiflora and its white form and fulgens. They are growing in good loam in a half-shaded bed. We only wanted an Italian autumn

be no apprehension as to the sets not growing. I have on occasion planted, with excellent results, edgings with sets on which there has not been a vestige of a root. The great thing is to provide a good quantity of soil for them to root into, and to make it as firm as possible by ramming both before and after planting.—K. P.

TULIPS.

TULIPS, as we know them to-day, are more than flowers of April, for they linger with us through May, and even to the threshold of June. Tulips, indeed, may be regarded as connecting-links between the first and second seasons, messengers of an advance

Fuchsias at Gravetye. 1916.

ripen to perfection. Growers on a large scale use potash in combination with other chemicals, while amateurs and private gardeners, when they can obtain them, resort to the use of wood ashes, which supply the necessary amount of potash when mixed with the compost. Possibly, the soil in your friend's case has become exhausted through being used for the same purpose two or three seasons in succession. If so, the remedy is either to replace it with new soil, adding wood ashes if you can obtain them, or an artificial manure of which potash forms a constituent. The latter should also be employed in the event of your being unable to change the soil.]

to let the many flowers open; instead, the frost soon came and blackened the shoots. W.

Replanting Box edgings.—This is a good time to undertake work of this description, as the new sets have an opportunity to become well rooted and established ere spring arrives. Box forms a very suitable edging to kitchen garden paths, and nothing has a nicer appearance when it is kept dwarf and regularly clipped. Overgrown edgings furnish an abundance of material for replanting with. This need not be planted in its entirety, as the older portions of the stems and roots can be cut away. So long as there are a few roots present there need

guard, antedating the greater glory of early summer flowers, like Pæonies, Irises, Roses, and Larkspurs, which broaden into beauty as the days pass. No bulbous plants are easier of cultivation than Tulips, and it is possible, without much difficulty, to have the various sections in bloom from February to May. To those who desire to have pots and bowls of bulbs in their homes in the early months of the year Tulips should appeal, inasmuch as they last longer in flower than most subjects, and may be grown either in soil or shell-fibre with much success when once their culture is understood. The colours, too, of the blossoms are so charming, ranging from faintest pink to deepest rose,

carmine, and crimson; from vivid scarlet to mauve, purple, and violet; from primrose to yellow and orange; with white in purest form, that anyone interested in window and table decoration may, by a careful selection, bring about combinations that will harmonise with the interior of any room. The Darwin Tulips are distinguished by their wealth of lovely self-colouring, their shapely blooms being borne on strong, tall stems. Cottage Tulips belong to a much earlier race, and in some instances have been lifted from the obscurity of old English and Scottish and Irish gardens. Both these sections lend themselves to colour schemes in gardens where herbaceous plants are grown and where their handsome blossoms show up amongst the wealth of the fast-developing foliage of May.

CULTURE IN POTS AND BOWLS.—To have Tulips in bloom in March and April in pots or bowls a long season of growth is recommended. It is, therefore, best to procure the bulbs early in autumn. Five-inch or 6-inch pots will be found a convenient size, and drainage should be provided by well crocking them. A good compost is turfy loam, with leaf-mould and coarse silver or river sand added, the whole being well mixed. Four bulbs will suffice for a pot. For growing in bowls shell-fibre is a suitable medium. This, if dry, must be thoroughly moistened, the material being pressed firmly into the bowls, but not made hard. The bulbs should be inserted until the crowns are level with the top of the fibre or soil, the receptacles will then be ready for removal to a cool, dark, airy place, where they may be left until about 2 inches of growth are visible. Whilst in this stage it will only be necessary to afford the bulbs water occasionally. After this they can be brought into the light and slightly warmer conditions. If they are removed to a greenhouse great care must be exercised not to expose them to more than gentle heat. Tulips, perhaps more than any bulbs, resent forcing. Probably that is the reason why many who do not own a greenhouse are successful with them, because the heat of a sitting-room is generally quite sufficient to lure them into bloom. It is futile to attempt the early forcing of any bulbs before they have made liberal root-growth, and this can only be achieved by early planting. Undue forcing is frequently the prelude to failure. Another source of disappointment attending the culture of Tulips in bowls and pots is keeping them too dry. When water is really necessary the soil should be soaked, and in the case of bowls any superfluous moisture drained away. The danger of over-dryness must be guarded against, especially after the bulbs show an inch or two of growth.

Tulips will do well in most soils, provided the situation is a sunny one, but do best in a light, rich, sandy loam. After the ground has been well dug in the autumn the bulbs should be planted 5 inches deep and about the same distance apart. In a heavy soil 3 inches deep will be sufficient. From the middle of October to the end of November is the best time to get the bulbs in. LEAHURST.

Kalosanthes coccinea and Rochea falcata.—These two pretty-flowering succulents, mentioned on page 542 by J. Cornhill, have undergone some changes of names since they were first introduced to British gardens. Take the *Kalosanthes*. It was, after a time, placed in the genus *Crassula*, and now, according to the "Kew Hand List of Tender Dicotyledons," it is transferred to the genus *Rochea*, the specific name of *coccinea* being still re-

tained. On the other hand, the name of *Rochea falcata* is now changed to *Crassula falcata*. I quite agree with J. Cornhill as to the desirable qualities of these two South African succulents, but the shifting about of names is a nuisance. It is not as if all authorities were agreed, but the game of battledore and shuttlecock is so persistently played with the names of plants that in referring to any plant by its botanical name one is never sure whether the one you know it by is in accordance with the latest naming. The names of Ferns in the "List of Plants Certificated by the Royal Horticultural Society" furnishes a case in point.—W. T.

WASTED EFFORT IN GARDENS.

In trying to carry out improvement of the flower garden, owners should remember that, as a rule, there is no merit in mere extent or area. In a garden mere size is nothing to boast of. Beauty in modest ways, as we see it in a cottage garden, is a better aim. Great size is against good gardening. There are so many needless walks and other *impedimenta* in our gardens that men cannot get to work in any simple way. Half the time is lost in cleaning the feet, seeing that edges are not injured, or in repairing them when they are; a lot of useless labour is caused, the time expended in which ought to be given to the growth of plants.

Then we have the endless shaving of lawns. The soft turf is the glory of our gardens, and forms the most delightful playground; but who can say that it is wise to mow, as people have boasted of, 40 acres of kept lawn? Soft lawns we want near our houses, and cannot take too much care of them, but the wide acres that are mown in many large country seats would be better cut at hay time. Flowering Grass is one of the most beautiful things in Nature, and our garden lawns would be at least as lovely. The Grass itself should be a beautiful garden. We should see in it, as we often see on an alpine meadow, fair bulbous flowers and other plants which will grow in English as well as in alpine turf.

After the Grass come the needless walks. Our own landscape gardeners are a little more economical in hideous walks than are the French, but we very often have four times too many walks, which torment the poor gardener by needless and stupid labour. The planning of these walks in various elaborate ways has been supposed hitherto to have some relation to landscape gardening, but the presence of one needless walk often spoils all possibility of good landscape effect near. Walks should be designed to go with one sweep wherever it is necessary they should go and be reduced to modest dimensions. Generally, all flower-beds are best set in Grass, and those who care to see them will approach them in that way quite as soon as if hard walks are brought near them. For the three or four months of our dullest season there is little need of frequent resort to flower-beds, but for the rest of the year the turf is better than any walk. I do not mean that a walk should not lead to the flower-garden, but that every walk not necessary for frequent use should be suppressed. Few have any idea how much they would gain, not merely in saving labour, but in the beauty of their gardens, by abolishing useless walks.

This waste of effort should be turned to good account in the growth of flowers. In many places miles of walks may be seen, bordered in many cases by long, naked stretches of earth. The gardener, with his few men, is impotent to turn such a waste into a paradise; his time and his

thoughts are eaten up by trivialities—barber's work, shaving Grass, and weeding walks eternally. To form a garden of Roses, or groups of choice shrubs, or beds of Lilies, or other noble hardy plants properly, as regards the soil and its depth, that the bed might fairly nourish its tenants for a dozen years is flower gardening. To such ends all good gardeners' labour should be directed. Instead of the never-ending scratching of beds in autumn and spring we ought to have a thorough preparation of one portion of the garden each year, so that it would yield us quiet beauty for many years to come.

Glasshouses are useful and charming helps for many purposes, but we may have noble flower gardens without a pane of glass. To grow Roses or Carnations in winter, to ripen the fruits that will not mature in our natural climate, to enable us to see many fair flowers of the tropics and sunny climes—for these purposes glasshouses are a precious gain, but for a beautiful English flower garden in the British Isles they are wholly needless. Therefore, one great source of expense may be saved, and the numerous glasshouses in our public and private gardens can then be turned to better use. It would not be true to say that good hardy flower gardening is cheaper than growing the masses of graceless plants that often disgrace our gardens. The splendid variety of beautiful hardy things and the ceaseless birth of novelties tempt one to buy. All the more necessary is it, therefore, not to waste money in stupid ways.

From an economical point of view nothing is more important than the due preparation of a flower garden soil by deeply trenching it. This well done in the first instance, and due after-attention given to mulching, but little, if any, artificial watering will be required, excepting in the driest season. There is much unnecessary labour expended in watering. Often-times, if the surface soil only looks dry, it is concluded that watering is needed, and accordingly it is given. 'W.

NOTES AND REPLIES.

Poor soil—manures for.—I shall be much obliged if you can tell me whether superphosphates would be useful to my soil, which is very poor. There is no sand or lime in it; but it is poor and light. The subsoil is yellow clay. I have trenched it deeply and heavily manured it, but this does not seem enough. Do you advise the above or basic slag or lime for flower borders?—T. S. BARKER.

[Yes, superphosphate would be of great service to your soil, and basic slag also, but the latter would have to be applied now, while the former would be best used in February or early in March. Basic slag is an excellent dressing for the lower spit when land is being double-dug or bastard-trenched in autumn. Quite half a pound per square yard may then be applied. Of the two we should prefer basic slag for flower borders, but, as before remarked, it should be applied now, for the reason that it is a slow-acting manure.]

Dwarf Fuchsias for the rock garden.—The best of the dwarf Fuchsias I have tried for the rock garden has been Bouquet, a dainty little plant, one of a series of hybrids raised by M. Lemoine, of Nancy. It is of erect growth, not more than 9 inches or 12 inches high. I had on a rock work one plant for upwards of fourteen years without any protection. S. ARNOTT.

Potentilla dubia.—This Cinquefoil deserves what "N. L." says of it. It is an excellent little plant for the crevices of stone pathways, rough steps, or old walls. In flat places on rockwork or in the front of the border it should be favoured with the top-dressing advocated by your contributor, and, if this is neglected, I have seen it lost after a lapse of years.—S. ARNOTT.

INDOOR PLANTS.

WINTER-FLOWERING BEGONIAS.

HYBRID winter-flowering Begonias are today the most valuable of all plants for blooming during the winter. They are the result of intercrossing *Begonia socotrana* with varieties of the tuberous-rooted section. They equal those of the Lorraine type for freedom of bloom, and greatly surpass them in size, form of flower, and wide range of colour. Messrs. Veitch, of Chelsea, were the first to take in hand these Begonias, and they raised many fine varieties. Messrs. Clibran, of Altrincham, have also raised many beautiful varieties, including Pink Perfection (clear blush-pink), Altrincham Pink (bright pink), Mr. T. H. Cook (rose-pink),

drained. All the varieties are easily increased from cuttings, which may be taken at any time from April to August. They are made from the young shoots which form in the axils of the leaves after the plants have completed their season of rest. Insert the cuttings singly in 2½-inch pots, using a sandy compost, and place them in a handlight or small propagating-frame where the temperature does not fall below 70 degs. Directly they have filled their pots with roots pot them into others two sizes larger, and so on, till they reach the flowering size. Cuttings rooted early will require 6-inch pots, and a later batch will need 5-inch, using the compost named above. A somewhat moist atmosphere is essential through the growing period and a temperature of 60 degs. to 65 degs. No

potting; indeed, they never flower so well as when the bulbs are closely packed together. Sometimes, however, the roots get into a bad state, and repotting then is absolutely necessary. The best time to carry this out is as soon as it can be seen that the bulbs do not intend to flower, when they should be shaken clear of the old soil and repotted. Whether they are placed singly in the pots or grouped together the drainage must be ample, and the compost selected good yellow loam, with a liberal amount of sand, and if of too adhesive a nature a little well-decayed leaf-mould to keep it open. This compost will keep sweet for a lengthened period, hence its value for such plants as this. During the winter and early spring the plants should be kept in a light position in the greenhouse and moderately watered in order to encourage good and free yet sturdy growth. Then, as the plants show signs of going to rest the water supply should be diminished, and when dormant the bulbs must be kept totally dry and well baked in the sun; indeed, they will require no water till the flower-spikes show, when water must be carefully given. If the clumps or masses get too large, and it is decided to divide them, this may be done directly the flower-spikes can be seen, for *Nerines*, unlike many bulbous plants, will develop their blossoms if disturbed at the roots. The spikes, however, must be a couple of inches long before this is done or failure will be the result. You must not, however, be surprised if many of these divided plants fail to flower the next season. Weak liquid-manure applied occasionally during the growing period is very beneficial to the *Nerines*, but care must be taken that it is well diluted, as anything tending to choke up the potting compost should be avoided.]

Kalosanthes coccinea.—I was glad to observe (page 542) Mr. Cornhill's note on this beautiful but neglected greenhouse plant. There are several reasons why the *Kalosanthes* has never become popular with amateurs, the chief being that the flowers are unsuitable for cutting, a consideration which in these days appears to outweigh whatever other good qualities a plant may possess. Notwithstanding this disadvantage, one cannot shut one's eyes to their value as pot plants. The *Kalosanthes* is beautiful when in bloom, lasts a long time in flower, and is not difficult to cultivate. Mr. Cornhill rightly emphasises the worth of cultivating moderate-sized plants. Peat and loam, with a little bone-meal added, make an excellent compost. The plants should always be given the sunniest position in the greenhouse, so that the growths may become well ripened.—LEAHURST.

Winter-flowering Begonias.—The bulk of the plants of the Lorraine type of *Begonia* should be placed in a house by themselves, preferably one that is not too lofty. Before arranging the plants therein the house should receive a good cleaning, recovering the stages with clean fine gravel or ashes. Allow the plants ample space for development and attend to their needs in the way of tying as the flowering shoots extend. In a temperature of 55 degs. to 60 degs. the plants will come gradually into flower and last over a long period.—A. W.

Shrubs for forcing.—A few shrubs, such as *Azalea sinensis*, Lilacs, Prunus, Wistarias, *Staphylea*, and Laburnums, are being potted up or top-dressed for forcing during the early spring. The flowers provide a valuable supply of cut bloom, and the plants furnish excellent specimens for decorating the greenhouse and conservatory. Many of these plants may be forced from year to year, provided they are given suitable treatment after they have flowered.—F. W. G.

Winter-flowering *Begonia Emily Clibran*.

Emily Clibran (light salmon, flushed orange, here illustrated), Optima (salmon), Lucy Clibran (orange, suffused rose), Scarlet Beauty, Vivid (bright scarlet), Britannia (bright crimson), and Elatior (rosy-carmine).

CULTURE.—When the flowers are over, a partial rest should be given until the end of March in a temperature of 55 degs. to 60 degs. At this time they need very careful watering; in fact, this is the most critical time of their existence. If they are kept moderately dry, giving just sufficient water to maintain the stems and foliage in a healthy condition, they will not suffer. After growth commences the plants need repotting in a compost, consisting of two-thirds good fibrous loam, one-third good leaf-mould, a little well-decayed cow-manure, and silver sand. The pots must be perfectly clean and well

overhead spraying is advised, as any condensation of moisture on the leaves is detrimental to their welfare. Pests that have to be guarded against are mite and thrip. An occasional fumigation with nicotine will act as a preventive of these pests.

F. W. GALLOP.

NOTES AND REPLIES.

Growing Nerines.—I possess several very fine old clumps of *Nerine Fothergilli*, *N. Fothergilli major*, and *N. cornusca*, but though each pot now contains more than a dozen bulbs, I seldom have more than four blooms from a pot, and sometimes none at all. I was told that *Nerines* should never be repotted, and should be well baked in the sun each summer. I should be glad of any hints as to cultivation.—M.

[Provided the roots are in good condition, *Nerines* will stand for years without re-

FRUIT.

CORDON PEARS.

Will you oblige by giving me the names of the best twelve cordon Pear-trees for a wire fence for early and late use? I should like them with the combined qualities of dessert and stewing. Also, are they best on the Quince or on the Pear?—N. J. S.

[Good varieties for cordons are Souvenir du Congrès, Louise Bonne of Jersey, Beurré Superfin, Beurré Hardy, Beurré Diel, Doyenné du Comice, Marie Louise, Thompson's, Winter Nelis, Glou Morceau, Bergamotte d'Esperen, and Easter Beurré. There are no doubt others equally good, but much depends upon soil and situation, so that in selecting varieties these should be taken into account. Deep planting is a serious evil, and should be avoided. Thoroughly trenching and draining are also of great importance. Heavy, wet clay will require draining and suitable ingredients, such as lime-rubble, charcoal, burnt soil, and other material mixed with the soil.

When on the Quince, which is the better stock, heavy mulchings of good manure should be applied twice a year—viz., in the autumn and spring, as it is useless to starve the trees. The roots being near the surface must be encouraged to remain there, so that a good dressing of thoroughly decayed manure from 4 inches to 6 inches deep is what is wanted to produce fine fruit. The watering of trees grown as cordons must also be attended to, as the roots, being near the surface, soon suffer in dry weather. A heavy mulch in the spring will do much good by retaining the moisture, and should, at the least, be 3 feet from the wall. Liquid manure is of great assistance to the fruit when swelling, well washing it down to the roots. Protection from frosts and thinning of the fruit are also necessary. Pinching and stopping during the growing season are also very important, and if these are attended to not much winter pruning will be required. What are known as dessert Pears are of no use for stewing, good sorts for this purpose being Catillac, Gilogil, and Verulam.]

NOTES AND REPLIES.

Black Currant Lee's Prolific.—Of late years Boskoop Giant has been so largely planted that other of our good old standard sorts have been somewhat neglected. The "big bud" disease has been a serious trouble, and has led up to the clearing of large areas of Black Currants, hence there has been a distinct shortage of this highly-favoured fruit for some time past. I have given up growing Boskoop Giant, which was said to be immune from the attack of "big bud," and now grow the Baldwin, Lee's Prolific, and Victoria, which give me heavy crops of fine berries and are free from "big bud." Boskoop Giant was remarkable only for the giant size of the individual berries. Lee's Prolific is well named, and those who plant this in place of Boskoop Giant, as I have, will find both profit and satisfaction. As the season of planting is with us the occasion may be opportune to some of your readers to reinstate the proved and time-honoured favourites of bygone days.—W. S.

Apple Langley Pippin.—This should, in time, become a popular Apple, its season, August and September, being one that does not provide much variety for dessert. True, there is the Worcester Pearmain grown in great quantities for market, but, apart from its brilliant colour, there does not seem any other outstanding merit. Langley Pippin is said to be a cross be-

tween Cox's Orange Pippin and Mr. Gladstone, parents that should produce quality. Mr. Gladstone is a handsome August fruit, but in many gardens shy-bearing, while in others it crops freely. Langley Pippin, of Pearmain shape and attractively coloured, has a soft flesh and pleasant, crisp flavour. When the merits of this early Apple become better known it will be freely planted, though not to the extent of the Worcester Pearmain. Langley Pippin, with me, makes quite an attractive bush, does not assume undue vigour, and is, therefore, likely to become a regular-bearing variety. Another of Messrs. Veitch's newer varieties, September Beauty, is said to be of the same parentage, but is not, in my judgment, comparable with the Langley Pippin. My trees of both these kinds were grafted, headed-back, established trees, and it may be that this double grafting may cause a variation in the character of any particular kind. At the same time, it is an easy way of substituting a new or a better Apple for one that is unsatisfactory.—W. S.

Apple Hambling's Seedling.—I have been much impressed with the fine keeping qualities of this Apple. It remains perfectly sound until March, which for a large-sized cooking Apple is considered a good record. With me, in standard form, it has not yet given a bountiful crop, but, like the Blenheim, it may fruit more freely when older. It is distinct in appearance, quite round, and smooth in outline, and very solid. It may possibly not give the best results grown in bush or pyramid form, as its growth is spreading. The Paradise stock restrains the exuberant growth of many Apples, and may do so in this case. At any rate, Hambling's Seedling, having such fine keeping qualities, is deserving of trial.—W. S.

GARDEN FOOD.

NOTES AND REPLIES.

Indian Corn.—Some time ago you had a paragraph about growing Indian Corn as a vegetable. I had some planted at once, and it came up and grew well, but now at this date (November 5th) the cobs are only some 6 inches long when stripped of their leaves, and it is not easy to get the Corn off when cooked, the husk part being very tough. Are my cobs too young? Was I too late in planting, or would the plants be better started in pots and planted out?—C. A. HOPE.

[You may have planted too late. The recipe you give we omit as of slight value. There is no need to prefer the short cobs. Long ones are good, the mistake is letting the cobs grow too old and hard. We find the Corn best eaten straight off the cob, dog-fashion, though there are various good ways. Plant on warm southern slope. Get best American varieties.—Ed.]

Celeriac.—This vegetable should soon be in use, and in these times of scarcity of workmen it is well to have plenty of it, as being less troublesome than the blanched Celery. In the garden it is easily grown, even in the wettest parts. The thing to desire is that the cook should make good and frequent use of it, varying the dishes made by its aid in stews or "hotpots," and also as a separate dish. It should be home-grown, as the market produce is often far from fresh or good. In growing it, the kinds with the largest roots are not the best, and some trial is necessary to find out the best kinds for the cook.—W.

Pumpkins and Gourds.—Were the value of Pumpkins and Gourds as vegetables fully recognised they would be grown much more extensively in this country. I fear that a certain amount of prejudice has much to do with their neglect, and my object in calling attention to them at this time is to induce all who may be in

possession of any at this season to take the greatest care of them for use during the coming winter, when many vegetables, and especially Potatoes, promise to be extremely scarce. Cooked and served properly I know of few vegetables which are more appetising than Gourds or Pumpkins. A large Pumpkin may be cut much in the same way as a cheese, and used as required; if stored in a dry place it will keep good for a considerable time.—EDWIN BECKETT in *Gardeners' Chronicle*.

Rice and Cabbage.—Take a good, fresh Cabbage, trim and take out the stalk, well wash, and cook (but not over-cook it). When it is done, press it with a clean cloth in the colander to get it as dry as possible; then chop it coarsely and return to the saucepan with 2 oz. of grated cheese, 1½ cupful of cooked Rice, and a small piece of butter. Season lightly, mix all well together, and serve very hot.—S.

Growing Celeriac (p. 556).—By mistake I was made to say "it grows best in the coolest and best parts of the garden." I meant the *worst* part of the garden. It is convenient to have a crop that one may put into the heaviest and wettest parts of the kitchen garden. No doubt it would grow in other parts, but I always put it in the heaviest and wettest spot.—W.

Couve Tronchuda.—From time to time short notes appear in GARDENING ILLUSTRATED about Couve Tronchuda, or Portugal Cabbage, but, judging by the little prominence it is given in most seed catalogues, it cannot be very well known. It comes in at the end of October and early in November. It will not stand too much frost, but a slight nip of cold weather improves the flavour. I am now cutting mine, and find it most useful. It takes up rather more room than ordinary Cabbage, but nearly every leaf is eatable, while the ribs may be cooked much like Seakale.—WOODBASTWICK.

QUINCE RECIPES.

QUINCE MARMALADE.—Pare and core and cut into pieces the fruit, put the skin and cores into a kettle, cover them with water and boil thirty minutes, or until tender. Strain off the water through a colander and as much pulp as will pass without the skins; to this add the rest of the fruit and three-quarters of a pound of sugar to each pound of fruit; boil it until it becomes a jelly-like mass; mash the fruit as much as possible. Turn into glasses and seal.

QUINCE BUTTER.—One-half gallon of Quinces quartered and cored, one-half gallon of tart Apples quartered and cored, two quarts of sweet cider, one pint of cold water. Cover the crock and stew gently until the fruit is very soft, then pass through a sieve. Add five cupfuls of sugar and cook until thick. The quantity of sugar must be governed by the cook's taste.

QUINCE JAM.—Take one pint of quince juice left from preserves, add one pound of sliced Apples, three-quarters of a pound of sugar; boil two hours, stirring well; pour into glasses while hot, and seal.

QUINCE AND PEAR SAUCE.—Three pounds light brown sugar, six pounds Pears, quartered if large, small ones cut in halves; nine pounds Quinces, quartered. Boil sugar, Pears, and Quinces nearly all day, taking care not to let them cook too rapidly, until both Pears and Quinces are of a rich red, and the juice an amber syrup. Can and seal tight. The fruit keeps its shape, the Pears having gained a fine flavour from the Quinces, and the Quinces having an added goodness from the Pears.

QUINCE HONEY.—One medium Quince and one cupful of granulated sugar will make one jelly glass of honey. Pare and grate the Quinces, then stir this grated pulp into a boiling syrup made of the sugar and enough water to dissolve it. Stir slowly and quite often until the pulp will remain suspended through the syrup. One should not get it too stiff. Put into jelly glasses, and when cool cover in the same way as preserves and jellies, and keep in the preserve closet.—*Rural New-Yorker*.

TREES AND SHRUBS.

PARROTIA PERSICA.

AMONG the trees that have kept their character this poor season this is one of the best. It is planted near a group of Pines, not the best place and not sunny, in ordinary cold soil. There is no need to describe the plant again. It is quite hardy and thrives in ordinary soil, but we are as yet ignorant of its character and needs. It is best, therefore, to group it with medium-sized trees.

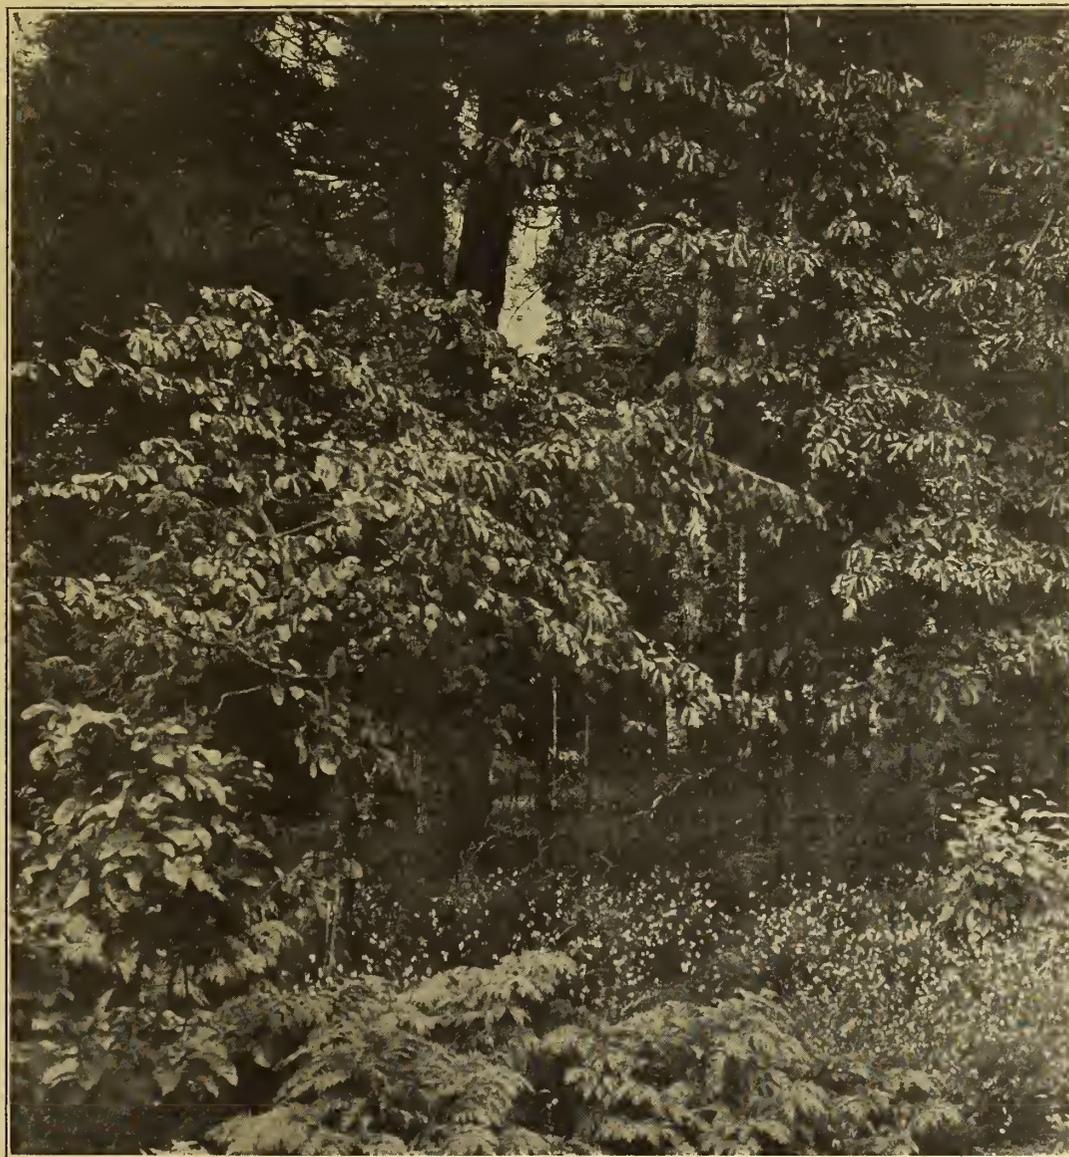

1848, but though a considerable time has elapsed since then, it is still an uncommon plant. A well-drained sandy loam that is, however, not parched up during the summer will suit this Parrotia best.—P. T.

NOTES AND REPLIES.

Diplacus glutinosus in the wild garden.—This is considerably hardier than many suppose. I have a colony established on a sunny slope in company with Ericas, and the masses of golden-buff flowers, which are produced from midsummer to the end of October, are very attractive. These plants were all raised from cuttings. D.

just read Mr. J. Harry Johnson's note on this plant, on page 539, and can corroborate all he says in regard to the Diplacus in its native land. There I have often seen the lovely red and yellow forms alluded to covering the hillsides, and I cannot forget the aromatic essences which arise from the bushes as one brushes through the chaparral.—A. T. JOHNSON, N. Wales.

Cotoneaster adpressa.—Minus fruit or flower beauty, this modern introduction from China would still rank high among its fellows by reason of its exceptional value for the rock garden. Virtually a

Parrotia persica on margin of Pine grove, Gravetye.

— The present autumn has not been at all favourable to those subjects whose decaying leaves assume a vivid colouring before they drop, but despite the dull weather this Parrotia has in some cases at least been very bright. In any selection of trees or shrubs remarkable for their autumnal foliage this must have a place, but in addition to this the flowers are also very pretty and interesting. Their most conspicuous feature is the red-tipped stamens. In general appearance and in the arrangement of the inflorescence this Parrotia bears a good deal of resemblance to the Witch Hazels (*Hamamelis*), to which, indeed, it is nearly allied. It was introduced to this country from Persia in

glutinosus is best planted when quite young, and likes a warm, light soil with good drainage and plenty of sun. Indeed, this shrub has many attributes in common with the Gum Cistus, and where one will thrive the other will usually do so. Winter treatment merely consists in covering the roots of the plants with a cone-shaped heap of ashes. It is also desirable to secure the trailing branches of the larger shrubs so that they will not be blown about by winter winds. In the spring these branches may, with advantage, be shortened right back to within a few inches of the base. This treatment conduces to finer blooms and more of them, as well as a more compact habit. I have

rock-clinging subject—so tightly does it press its prostrate branches against the rock—it is the best of them all for this purpose, covering a few feet square in the course of three or four years. To this good attribute must be added free growth, hardiness, and a neat habit equalled by none. In common with others of its class, it provides a leaf-colour effect late in autumn prior to casting its foliage. The flowers are pink, succeeded by scarlet berries. Covering its allotted space on the rock and encroaching on to the path, it will root into the mingled gravel and soil in its onward course. In dryish places the slower growth is more minute—perhaps more pleasing.—E. H. JENKINS.

CHRYSANTHEMUMS.

CHRYSANTHEMUM NOTES.

WITHIN recent years there has been introduced a type of Chrysanthemum of far better quality than what we know as outdoor kinds, but it is not so early in bloom, and, therefore, requires some sort of protection. These semi-early sorts are in bloom now. The protection necessary applies only to the flowers, for they are growing in the open ground. It is best to grow them in beds of, say, three rows, 2 feet apart, and then temporary protection can be readily fixed above to ward off rain and frost, with mats, or the like, for side shelter. The varieties are about a yard in height, are generally sturdy, and stronger in stem and leaf than the true earlies. They are amenable to disbudding; in fact, grown without thinning, they are not nearly so useful, from my point of view, for producing blossoms of high quality which fetch good prices in the market, and are valuable for filling vases, etc., in the house. From one dozen to two dozen flowers are allowed to each plant, one bloom to a branch. These modern semi-early sorts were probably obtained by crossing the outdoor ones with the November Japanese kinds. At any rate, we get in them a type that is most useful during early October. The following are excellent:—*Amirante* (chestnut-crimson), *Countess* (white), *Cranford Pink*, *Cranford Yellow*, *Cranfordia* (yellow, fine), *Dolores* (deep bronze), *Miss F. Collier* (white), *Mrs. Roots* (white), and *Le Pactole* (light bronze, of French origin). There are a few others, but it is not worth while to give their names, because, as yet, they cannot be obtained from the raisers.

Noticeable among the newer Japanese kinds of the big-flowering type is the splendid habit of growth. We seldom see nowadays new varieties of indifferent constitution. These newer varieties are mostly short or, at least, of medium height, and with exceptionally large foliage. I am especially pleased with *Mrs. M. Sargent*, a strong grower that has flowers of an incurving form, which are white, with a distinct green tinge. This should be favoured by amateur growers, and, if I mistake not, it will be capital from a market standpoint. It was raised by Mr. Bryant, who gave us *Queen Mary* and *Mrs. G. Drabble*, two first-rate whites. *Edith Cavell* (deep bronze) is thought by some growers the best of last year's novelties. *Frank W. Ladds* is distinctly promising, with flowers of a clear yellow shade. This, while useful for show, will be valued for what I will term ordinary culture. The sport from *Wm. Turner* named *Mrs. H. Tysoe* looks most promising this year. It is a yellow variety that will be esteemed for exhibition. Of the first-named I saw some exceptional bush specimens the other day. The plants are thinned to a dozen branches, each bearing a sturdy-looking flower-bud. When in full bloom the head of white should be a mass a couple of feet across. Unusual varieties in these days are the old-time *Mrs. G. Rundle* and its yellow sports. I had thought them quite out of date, and yet I am looking forward to flowers from these plants creating considerable interest when seen in public. The stock whence the cuttings came in this case has been in the care of a grower for forty years.

In growing Chrysanthemums under glass we should endeavour to keep the surroundings dry, and if there be fire-heat there should also be air, more especially through the top ventilators. Cold draughts are harmful. It is well to do what watering is necessary in the early part of the day, then at night there is less chance of

damage by condensed moisture, a frequent forerunner of decay or damping. Continue to give stimulants to the plants when the flowers are opening; indeed, this assistance is then needed as much as ever to finish the flowers. Soft side shoots should be rubbed out, and the growths at the bottom removed; such are useless for cuttings. Better material for propagating will follow later, when flowering is past. The rage for

SINGLE-FLOWERED varieties of late years has resulted in numerous pretty varieties if we judge the flowers only, but one could wish for better growth in these in too many instances. We cannot complain of any like the "Mensa" type, which is the ideal of to-day, although some might desire a slightly dwarfer growth. *Aristocrat*, amongst the new sorts, is very promising. Presumably singles are preferred where disbudding has been done—say, from ten to eighteen branches to a plant, each branch carrying but one flower. The gain in size matters little, but what we get in substance does, and the flower-stems then come strong enough to hold the blossoms well up. A rather new class, *Anemone-centred singles*, is being tried this season. I liked *Ceres* and *Aphrodite* when exhibited last year. *Kathleen May* and *Snow Queen* have been noted before.

H. S.

ROSES.

NOTES AND REPLIES.

A large Dog Rose.—A fine old bush, almost a tree, of *Rosa scabrata* is just at its best, and is bearing hundreds of its large, deep pink, single Dog Roses. It is a seedling form of *R. canina*, but its flowers are twice as large as those of the wilding, a fully expanded flower being over 4 inches across and of a warmer and more uniform shade of pink. It is the best single pink Briar Rose I know of to form a large self-supporting specimen in the Grass, either on a lawn or in the wild garden. All the attention it requires is the removal of some of the oldest wood now and then to allow the long arching shoots room to develop. Then throughout June they should be covered with the shell-pink flowers, and in autumn and winter, until the birds feast on them, the large hips are very ornamental.—E. A. BOWLES in *Garden*.

Rose Hugh Dickson.—This does not flower so freely as General M'Arthur or Richmond, but its blooms are finer than those of these popular Roses. It is such an excellent autumnal variety that it is worth special consideration for this virtue alone. Perhaps at times its colour might be more glowing, but it deserves all the praise it has received since it was introduced about thirteen years ago.—SUB ROSA.

Rose American Pillar.—This has again been very fine this season, and in a number of Scottish gardens it is a great favourite. As a pillar Rose it is superb, but it is a charming variety as a tall weeping standard. The large pink flowers, of a deep shade, are in clusters, and borne very freely. It makes vigorous shoots. The foliage is very beautiful, and no garden where climbing Roses are grown should be without *American Pillar*.—A.

Rose Debutante.—This is a charming Rose for a high arch or pergola. It is excellent in the gardens of Captain Sir C. Hope Dunbar, Bart., at St. Mary's Isle, Kirkcubright, where it has been for some years on an arch. The long, drooping branches, with their abundance of semi-double, soft-pink flowers in clusters, are very effective. *Debutante* blooms for several months, and this is in itself a strong recommendation.—S. A.

Rose Flame of Fire.—In a Scottish garden the other day I saw this in fine condition. The flowers are comparatively small, but they are bright and showy, and are also freely

produced. The colour, as described in "The Rose Annual," is a "deep orange flame," and it is not easy to think of anything to convey better the brightness of the colouring of this Rose.—SUB ROSA.

Rose (H.T.) H. E. Richardson.—This Rose, introduced by Messrs. Hugh Dickson in 1913, is blooming well this season, and promises to be a good garden Rose. The growth, which is upright, is free, and the flowers, of beautiful form, are of a lovely velvety crimson. In slight shade during mid-day, its exquisite colour is enhanced by the perfect form of the blooms.—Scot.

Rose Tea Rambler.—After growing this for several years, I have decided to replace it by a hardier Rose. *Tea Rambler*, pretty though it is, is not suitable for gardens where the wood does not get thoroughly ripened in autumn, and where the winters are inclined to be severe. Various friends have had the same experience with this Rose.—S. W. Scot.

GARDEN PESTS AND FRIENDS.

THE ONION-FLY.

THIS year I have sown Onions several times for early and late crops, but in every case they have been attacked by the Onion-fly. I have used paraffin and sand without effect. The same treatment has warded off the Carrot-fly, and this year I have got the best crop of Carrots I have ever grown. I get one pint of paraffin and a bucket of dry sand. I mix the oil and the sand together and sprinkle it round the roots of the Carrots as soon as I have thinned them the first time, then in about fourteen days I go over them again and thin and sprinkle as before. I do the same with my Turnips and other young stuff. It is just possible in the case of Onions mentioned above that the mixture of sand and paraffin was applied too late. Kindly tell me what I had better do to get rid of the Onion-fly.—ONION-FLY.

[The Onion-fly lays its eggs at the base of the young plants during April and May, and the grubs, when they hatch out, begin feeding on the bulbs and burrow into the hearts of the plants, which soon begin to fail and finally collapse. In the case of a bad attack the plants can then be pulled with little or no effort from out of the drills, as the roots by this time are partially or wholly destroyed. When in this condition every affected plant should be pulled up and burnt. Remedial measures to take when there have been previous infestations are to sow rather deeper than usual, as shallow sowing renders the plants susceptible to attack by reason of the base of the plants being then either on the surface of the soil or but little below it. By sowing more deeply the vulnerable portion of the plant is then buried, and for this reason it is recommended, when an attack is apprehended, that soil be drawn up to the plants on either side of the drills so that the "fly" is baffled and unable to get at the base.]

Some growers water the soil with paraffin and water, others strew sand or sawdust saturated with paraffin between the rows, but the results are not altogether satisfactory. The best way when this pest has been troublesome is to grow the crop in another part of the garden, as far removed from the infested area as possible, to sow the seed as early as circumstances permit, and at a rather greater depth, so that not only shall the base of the plants be lower in the soil, but that the outer cuticle shall become hardened and less liable to be pierced by the insects when the egg-laying period arrives. It is also a good plan to dig in a soil disinfectant or strew sufficient lime and salt on the ground to whiten it previous to preparing the site. The same treatment should be meted out to the old bed, and then double dig it, by which means all insects, pupæ, etc., will be placed beyond

all chance of making their escape and doing further mischief.

It is a well-known fact that plants raised in autumn, as well as those raised in the early part of the year under glass, are seldom attacked, as the bases of the plants are too hard and buried too deeply for the insects to get at them, and this furnishes the clue as to how best to combat the pest. In some instances where losses have been serious, growers have abandoned outdoor sowing and raised the plants during January under glass instead. These, when large enough, are either pricked off into frames or boxes and finally planted out as soon as circumstances permit in April. By these means losses from this cause are reduced to a minimum.]

Lavender disease.—A destructive fungus disease has broken out among Lavender plantations. An account of it is given in the last number (5) of the *Kew Bulletin*, from which we take the following particulars:—Attention was first called to it

ROCK, ALPINE, BOG, FERN, AND WATER GARDENS.

GENISTA SAGITTALIS.

This is an interesting and useful rock shrub associating well with rockwork and growing and flowering freely with ordinary treatment. It appears to prefer poor, rather dryish soils, and certainly a sunny position. Soils of medium texture might well be freely incorporated with gravel, old mortar, pulverised rock—anything, indeed, which will assist root warmth and drainage. Grouped near a sunny rock-ledge, with a slightly inclining bank behind and smaller rocks distributed over the surface, it is seen better thus than on a quite level spot, and better still if midway between the line of vision and the soil. This prostrate broom merits some such consideration. Six inches or so high, it has curiously-winged or two-edged branches, above which, in a leafless terminal spike, the yellow flowers rise. This South European species flowers in

the winter months, which was recommended by Mr. Reginald Malby in some notes on this plant in one of the gardening papers a year or two ago. Mr. Malby considered that the clumps with glass on flowered better. There is no question mine flowered better than some others I had (uncovered), but I am not sure that this was not due to the position and treatment rather than the glass covering, as it is my opinion that the flowering tufts are formed before the glass is put on. In my case, where the garden is situate within half-a-mile of some large works, the covering of glass helps to keep the plant cleaner and probably healthier during the winter months. Other plants I have in a shallower and more limey part of the moraine, while flowering fairly well, are not so fine as the above, and part of them was affected by the dry weather we had immediately after flowering, possibly owing to not having so deep or free a root-run.

All the plants mentioned above are well away from other plants, so that, in my case, there is no question of plant association being required for successful culture. I have lost plants that have been planted in ordinary soil, and it is very important that they should not be covered up by strong-growing neighbours. I was in a part of England where this *Gentian* grows wild, at the latter part of June last, but it was much too late to see it in flower. Of the few plants I noticed, some were pretty clear of other vegetation, being in one case in quite a natural moraine, where the plant was flourishing quite clear of other plants. In another case I noticed it among the stones deposited by a small stream-side; they were also in among the short Grass such as is usually found in high, hilly pastures.

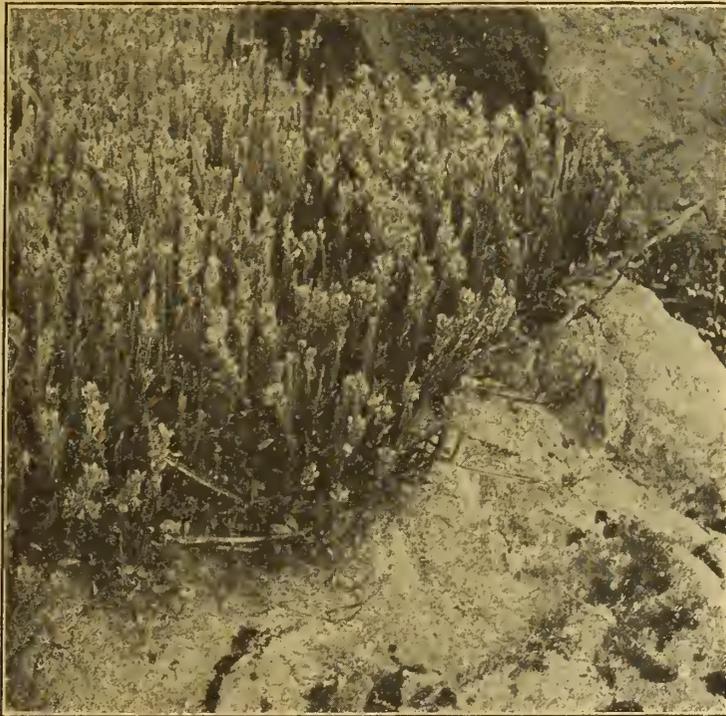

T. A. LOFTHOUSE.

Middlesborough.

NOTES AND REPLIES.

Saxifraga oppositifolia.—I have found very little difficulty with this interesting and welcome early-flowering Saxifrage, either on the moraine or in specially-prepared places in the rock garden. The important thing is to have the soil gritty (lime for preference), open, and well drained, and to see that the plants are not overgrown or shaded by other plants or shrubs, this preventing the plants ripening properly, and thus setting flowers for the following season. Of course, it is quite possible that they will not flower so freely after a sunless season such as it has been up in this part of the country this year. I do not think there is any question that the want of sufficient sun during the growing season has an effect on the flowering of many species during the following season. My plants, both on the rock garden and on the moraine, usually flower quite well where the open conditions are provided. After flowering, the plants are well mulched with a limy compost, and in dry weather occasionally watered. The only trouble in this part of the country is that at the time of flowering we usually have cold, frosty nights and the early morning sun bleaches the blooms. Rain, also, often following, tends somewhat to shorten the flowering season. Of course, one could protect them to some extent with glass, but this is somewhat difficult where there is any quantity, and, of course, takes away from the effect.—T. A. LOFTHOUSE, *Linthorpe, Middlesborough.*

Conandron ramordicoides.—This has proved a puzzle to many British growers. To see it in an alpine-house is to make one long to have it happy in the rock garden. Its big, glossy, light green, Begonia-like

Genista sagittalis in the rock garden at Friar Park.

at Kew last year when two large beds of Lavender purchased from a nurseryman were seen to be dying from some cause. Affected shoots presented a dirty brownish-grey colour, and the bark tended to split away in flakes. At first only individual shoots were affected, but finally the whole plant collapsed. It was found that the cause was a fungus known as *Phoma Lavendulae*, which appears to attack Lavender only. It spreads by means of spores, which are produced in immense numbers on infected plants, and, wintering in the bark, vegetate freely in spring. By the removal of all affected shoots in autumn the disease may be kept in check. *Phoma*, according to Masseur, is a large genus the species of which form crowds of black microscopic dots on stems and leaves. They are known to attack the Goosberry (Shoot spot), Cabbage (Stem rot), Carrot, Swede, Mangold, Wheat, and in Australia the Grape Vine. One of them (*P. solanicola*) attacks the haulm of the Potato, causing the leaves to wither and checking the development of the tubers.

May and June. Cuttings root quite well in July and August, or in early spring, selecting always non-flowering shoots of 2 inches long or thereabouts.

E. H. JENKINS.

GENTIANA VERNA.

[To the Editor of GARDENING ILLUSTRATED.]

SIR.—In reference to the notes in a recent issue relating to this plant, from my experience I do not think it depends on a close association with other plants for its establishing itself and flowering satisfactorily, plants I have in a moraine flowering freely. I have a small patch of the plant in a deep moraine which had the upper part to a good depth filled in mostly with whinstone chippings, in the first instance. The plants, which at present cover an area of about 9 inches by 4 inches, had over seventy blooms on last spring, and formed a beautiful clump. After flowering, I cut most of the dead blooms off, mulch with lime and a little sand, and water in dry weather. I have covered the above clump with a sheet of glass during

leaves are handsome, the purple and white yellow-eyed blossoms on short, stout, fleshy stems making the picture complete. Those who have seen the Conadron at home in Japan agree in thinking that it should be hardy with us, but it always seems to me that our winters are too wet, even for a plant which, in its native land, frequents deeply-shaded places.—S. ARNOTT.

Primula capitata.—This is valuable because it blooms in the autumn, and it is often in flower through September and into October. It is quite easy to grow in a cool, well-drained, but moist site, and I find it appreciates a little lime in the soil. My plants were blooming well in the early part of October, and they remain in bloom for some weeks. It seeds freely and is easily raised.—N. L.

Phlox amœna.—This delightful little Phlox is blooming freely now (the end of October); indeed, I find it quite as free flowering now as it is in the spring. It is of quite as easy cultivation as the subulata section, but does not grow nearly so rapidly nor make such a big spreading patch with me. It is a very dainty little species, and to my mind one of the loveliest of the dwarf Phloxes. I grow it in gritty, fairly rich soil in a sunny situation. It is easily increased from cuttings.—W. O.

Saxifraga geranioides.—This Mossy Saxifrage is not so often seen as most of this section, but is quite worth growing, and very distinct. The rosettes are much larger than those of most of its near relatives, and a good plant makes a fine contrast to the more ordinary forms. The white flowers are of good size and carried on branching spikes.—N. L.

THE WEEK'S WORK.

OPEN-AIR GARDENING.

IN BLOOM NOVEMBER 8TH.—*Convolvulus mauritanicus*, *Dwarf Campanulus*, *Parochetus communis*, *Mertensia echioides*, *Potentillas*, *Linarias*, *Armeria Lauchiana rosea*, *Eriogonon mucronatum*, *Hardy Cyclamens*, *Sternbergia lutea*, *Crocus speciosus*, *Tufted Pansies (in variety)*, *Sedum Sieboldi*, *Meconopsis cambrica*, *Valerian*, *Chrysogonum virginianum*, *Verbena venosa*, *Gazania splendens*, *Pentstemons*, *Antirrhinums*, *Nepeta Mussini*, *Anemone japonica*, *Lobelia cardinalis*, *Salvia Greggii*, *Corydalis thalictrifolia*, *C. lutea*, *Helianthus*, *Michaelmas Daisies (in variety)*, *Phyllis capensis*, *Hydrangea paniculata grandiflora*, *Hypericums*, *Climbing Roses*, *Clematis (in variety)*, *Escallonia montevidensis*, *Ceanothus (in variety)*, *Solanum jasminoides*, *Hardy Fuchsias (in variety)*, *Andromeda polifolia*, *Jasminum nudiflorum*, *Laurustinus*, *Lacatera Olbia*, *Veronicas (in variety)*, *Genista hirsuta*, *G. tinctoria*, *Myrtle*, *Ericas*, *Menziesias*, *Pampas Grasses*.

THE WEEK'S WORK.—*Chrysanthemums* have been valuable in the garden this autumn. As the flowers are now over the plants have been cut down and those required for stock lifted and placed in a cold-frame, covering them with leaf-soil to a depth of 3 inches. All Gladioli have been lifted, labelled, tied in bundles, and hung up to dry preparatory to storing them for the winter. *Lobelia cardinalis* is still flowering. The plants will not be lifted until cut down by frost. This *Lobelia* is valuable for colour-effect, while for cutting it is excellent, the spikes lasting well in water. It thrives in good, strong loamy soil enriched with plenty of stable-manure and an abundance of moisture at the roots. The plants often give considerable trouble when lifted and stored for the winter by what is known as damping, the whole plant literally rotting away. This happens when the plants are lifted from the border, stored in houses, and kept without water. It is really dry rot. This difficulty will not occur if the plants, as lifted from the border, are planted in boxes, using good soil with plenty of sand added. Give a good watering to settle the soil among the roots. Place the boxes in a cold-frame, removing the lights whenever the weather is open. Water as often as required. The roots will be active all through the winter without making any top growth. Early in March they may be divided into single crowns,

each having good roots. Plant them again in boxes, allowing them plenty of room, or, better still, pot them singly into 3-inch pots, subsequently shifting into 5-inch. Harden off and plant out in May. *Amaryllis Belladonna*, planted under a warm wall, has flowered well this season. All flower-spikes have now been removed and the bulbs top-dressed with good loam, a little lime-rubble, and well-decayed manure. The present is the most suitable time for planting *Roses*, provided the ground has been well prepared as advised in former notes. For general cultivation in beds the Hybrid Teas will be found the best. Though there are numerous methods of forming *Rose gardens*, the system of planting a bed with one variety has much to recommend it. The plumes of the *Pampas Grass* have been very effective for several weeks past. If for any reason it is considered necessary to lift and divide any large clumps, the present is the most suitable time to undertake the work. Division of old clumps is sometimes advisable, as when the crowns become overcrowded the plumes cannot develop properly, and many are smothered. If division be carefully done, no harm will accrue, and the planted pieces will flower the following season.

F. W. GALLOP.

Lilford Hall, Oundle, Northants.

SOUTHERN COUNTIES.

Chervil and Tarragon.—Handlights should be placed over both to preserve the leaves and tops for present use and prevent their being destroyed by frost. Some roots of the latter should be lifted, potted, and placed in gentle warmth to maintain the supply in the depth of winter.

Mint.—A good supply of roots should be hoaxed and treated similarly to the foregoing. A portion of a bed cut over a short time since is now pushing up a great quantity of young growths. Handlights or a frame would afford ample protection against ordinary frost.

General work.—Recent frosts having destroyed *Scarlet Runners* and late *Peas*, both will now be cleared away and the sticks preserved for future use, if not for the same purpose. Old hotbeds should be turned and thrown into a heap for a week or so, prior to wheeling the material to where it is required some frosty morning. Turning is generally the means of the mass becoming heated again to a certain extent, which hastens the decomposition of the outer portions of the beds, which are apt to get dry and decay but little. Heaps of farmyard, and particularly stable, manure always pay for being turned in advance of the time they are required for dressing the land.

Forcing shrubs.—Where a home supply of these is grown they should be lifted and potted forthwith, standing them afterwards outdoors on a bed of ashes and wide enough apart for some loose litter to be worked in between and over the tops of the pots to prevent their being split by frost. Potted and protected thus in good time, and with their heads exposed to the elements, they respond the more readily when introduced to heat. Even when a supply has to be bought in, the plants should be treated in the same way.

Bush fruits.—This is a good time to prepare ground for the planting of new breaks of *Red*, *White*, and *Black Currants*, as well as *Gooseberries*, with a view to replacing existing plantations which have become worn out. The latter should be allowed to remain for the present or until the newly planted bushes come into bearing. For the sake of conveniently netting the breaks in winter and again when the fruit ripens, or, what is still better, enclosing them with wire netting stretched on a properly constructed framework, the breaks should be arranged and planted accordingly. A portion of the netting in the latter case should be capable of being removed at the sides after the crops are cleared, as it is not necessary nor expedient to exclude birds the whole year round. If new breaks of *Raspberries* are required, the top portion should be permanently covered with wire netting. The sides can be enclosed when requisite either with the same or with tanned

string netting. These should be planted in consecutive rows 5 feet to 6 feet apart, allowing a distance of 18 inches between the stools, and be trained to wire trellis 5 feet in height. The autumn-fruiting varieties are best grown in a separate break, or a good way is to plant them on either side of one of the less frequented footpaths and train to a wire trellis. The soil should be liberally manured and deeply dug for *Raspberries*.

Fruit-tree planting.—Preparation for the planting of all kinds of fruit-trees is now being pushed forward. In the first place, all worn-out and useless examples will be grubbed, whether in the open or against walls, and care taken to see that all the old roots are searched for and removed from the soil. Holes for the reception of the new trees will be opened out wherever possible some distance from where the old ones stood, and some fresh compost placed beside them for covering the roots with and to give the trees a good start. The stations for *Apricots* will receive special treatment, a quantity of calcareous matter being added to the staple in addition to some good fibrous loam.

Manuring.—The first frosty morning manure will be wheeled out and spread between the rows of *Currants* and *Gooseberries*, and afterwards pointed in—i.e., after pruning is completed. The *Raspberry* quarter will also receive a liberal dressing.

Bedding plants.—*Pelargoniums* in boxes in heated pits need looking to now and again with a view to removing dead leaves and any cuttings that may be damping off. In fine weather it is always advisable to afford a reasonable amount of ventilation both at the back and front of the pits either by tilting the sashes on wooden hocks or sliding every alternate one down and pulling the others up a few inches. *Calceolaria* and *Pentstemon* cuttings also need the same amount of attention.

Gladioli.—These should now be lifted with a little soil attached to the roots and placed in a cool shed to dry off, when they can be cleaned and put into bags or boxes during inclement weather.

Plant-houses.—The time has now arrived when there should be a sensible reduction made in the temperature of the stove and intermediate-house, 60 degs. to 65 degs. by night and 70 degs. by day being ample in the first instance till after the turn of the year, 60 degs. and 65 degs. being sufficient in the last-named case. With less heat, syringing and damping must necessarily be done with a lighter hand and less frequently. Watering in all cases should be done during the early morning now, or as soon as it is sufficiently light to allow of its being done properly. Shadings and lath blinds should be taken down, dried, and stored in a dry place. The roof glass should then be washed with a view to admitting all light possible during the next three months. The cleaning of the interior can then be carried out the first convenient opportunity.

Tuberous Begonias now past their best require to be placed in a *Peach-house* or *viney* until the tops die down, when any dry frost-proof place will afterwards afford suitable quarters. The same treatment is also suitable for pot-grown *Liliums* in variety. Pot-grown *Fuchsias* may also be rested with them where no other suitable place can be found.

A. W.

MIDLAND COUNTIES.

Fruit-houses.—The pruning, training, and cleansing of *Peach-trees* are being pushed forward as quickly as possible, as there is not so much danger of damaging the buds now as later. Trees which have been unsatisfactory should be attended to. In nearly all cases of failure the trouble will be found at the roots. If the renovation is attended to before the turn of the year the trees will have time to recover from the check before they start into growth. Old trees with plenty of young shoots may have some of the older branches removed to make room for young fruiting wood. A few old branches removed every year will keep the trees furnished with young fruiting wood. After pruning is finished tie the shoots

into bundles and wash the house thoroughly, and finally wash the shoots with Gishurst compound. In training the shoots it may be found that there are still too many of them, and a few more should be cut out, as it is a great mistake to crowd the young wood. When the training is finished the borders must be attended to as described in previous notes. It is important to allow the trees a long period of rest before starting them again into growth, therefore the houses should be thrown wide open during the time when growth is dormant. See that the trees, especially those growing in inside borders, do not suffer from want of moisture.

Hardy fruit.—The pruning and training of all wall trees are being pushed on as fast as circumstances will allow. The Apricot, Plum, and Pear require similar treatment to that recommended for the Cherry. The branches of Apricots and Plums—especially Apricots—sometimes die back without any apparent reason. In such cases the dead branches should be removed before the general pruning is commenced, as it will be necessary to rearrange the whole of the tree in order to fill up the gaps. Both kinds produce their fruit on spurs, also on matured shoots of the previous year's growth. As the best fruits are produced on the previous year's wood, it is desirable to retain as much of this as possible, but never to the extent of overcrowding the branches. Shoots of medium strength may be left intact with the exception of those of the Pear, which usually form a blossom-bud at the point, and need, therefore, to be taken out if the extension of the tree is desired. Strong leading shoots should be pruned to half their length. All spur growths of the current season should be cut back to two or three buds. Old-established trees with unsightly spurs should have a few of the spurs removed annually. Fig-trees have been unfastened from the wall and the branches tied in bundles, so that when very cold weather sets in they may be easily covered with straw and mats. This protection will often save the first crop of fruit the following season.

Primulas require rather drier surroundings during the flowering season than were maintained during the period of growth. A little clear, weak soot-water may be given occasionally. Great care must be exercised in watering. The plants are best kept slightly on the dry side during the dull season, but care must be taken to prevent excessive dryness. If the flower-spikes are likely to fall over they should be tied to neat stakes. In the case of small plants, a few pieces of fibrous loam pressed firmly around the base of the plants will make them secure. Water should be sparingly given to plants in cold-frames, and the mornings of fine days are the best time for its application. Mats and other coverings should be at hand ready to place on unheated frames when frost threatens. It is also well to place similar coverings on very cold nights on the glass of heated frames. This is a better plan than increasing the amount of fire heat.

Celery.—The latest plants will now be earthed up finally, doing the work when the leaves are dry. Make the soil firm as the work proceeds, and take care to leave the top foliage clear of the soil.

Broccoli has made abundant growth, but it is sappy and immature. The plants will, in consequence, be liable to injury by frost directly hard weather sets in, unless laying is resorted to. There is no better method for protecting them, and if properly done will, at least, save most of the plants, notwithstanding severe frost. The work is done by taking out a trench at one end and heeling the plants over, placing their heads towards the north, arranging the soil evenly and firmly over the whole of the stem. The slight check caused to growth will be beneficial rather than otherwise. This work should be completed, if possible, before the end of the present month. Should unusually severe weather occur it may be necessary to lay over the plants some light material, such as Bracken or straw. A very light covering will suffice, and this should be removed directly the weather becomes warmer.

Parsnips are of much better flavour if lifted direct from the open ground when needed

for consumption. Nevertheless, it is advisable, in case of severe frost, to lift a part of the roots and store them in moderately moist sand. If this is not done it will be necessary to cover a portion of the bed with long litter or leaves to prevent the frost penetrating into the ground.

Seakale grown to provide crowns for forcing will now be all lifted, and the crowns stored in sandy soil in a convenient place in the open, where they can be drawn upon as required. The rootlets will be trimmed off, and in bad weather will be made into sets or thongs for planting next spring. I force Seakale in a dark corner of the Mushroom-house, introducing a small batch weekly, thus keeping up a constant supply.

Spinach.—All decaying foliage should be removed from autumn-sown Spinach and the soil between the rows broken up with a hoe. Overgrown plants should be picked over, whether the leaves are required or not, as this will encourage the development of clean, stocky foliage, which will withstand the winter better than fully-grown leaves.

Lettuces in cold frames need to be examined frequently, and all decaying foliage removed. The soil between the plants is stirred occasionally to prevent it becoming sour. The lights are removed on dry days, replacing them at night. Damping is the worst trouble with this crop in winter, and should be avoided as far as possible by tilting up the lights in rainy weather. If any space is available in cold pits or frames, this may be filled with late planted Lettuces from the open borders before they are injured by frost or heavy rains. If lifted carefully with a good ball of soil they will prove a valuable crop before the winter is over. F. W. GALLOP.

SCOTLAND.

Digging and trenching.—There is a scarcity of spadesmen, both skilled and otherwise, so that on all favourable opportunities this important work should be pushed on as rapidly as possible. It is of more importance that the digging and trenching be forwarded than to spend time at this season in tidying up—work which, just now, is, after all, to a certain extent labour in vain. It will be found advantageous to prepare two or three breaks or borders before digging begins. Alley-ways ought to be cleanly spaded, manure wheeled and spread, and the openings taken out, so that there may be no interruption when the digging begins. Trenching, it may be feared, will not be general during the coming season, but where it can be done, even to a limited extent, the trenches can be utilised for burying much rubbish which would otherwise require to be wheeled out. The weather having been favourable for this work, the Onion quarter, and that upon which Brassicas will be grown next season, were trenched in the course of the week. The only other break which will be treated in this way is that which will be devoted to Peas. Manure is being freely used, more especially in those portions which are not being trenched.

Hardy flower borders.—Not for several years has the display endured so long. Generally speaking, in this locality the earliest frost arrives about the middle of October, and is sufficiently severe to destroy the hardy flowers. At this late date there are still many things which are in quite passable condition. Helianthemums, Rudbeckias, Morina longifolia, Gypsophilas, Asters, Pyrethrum uliginosum, Salvias, and many others are yet blooming freely, in addition to plants more particularly associated with this time of the year, such as Eupatorium ageratoides and Schizostylis coccinea. It may be worth mentioning that the Dropmore variety of Anchusa is yet flowering in no half-hearted way. Fuchsias in the hardy flower borders are yet in fine form, and will continue to be gay until cut by frost. Roses, if not quite so good at this date as in more favourable years, are yet fairly numerous, and Clematises continue in bloom.

Shrubberies.—In the course of the week a look round was given among shrubberies—chiefly with a view to observing the likelihood

of a crop upon the berry-bearing varieties. The inspection revealed that, with one exception, the crop will be most disappointing. Hollies are a failure; where there are a few berries it may be safely assumed that the birds will not permit them to mature. The Snowberry, usually loaded with its waxy-white fruits, is but sparsely clad. This, however, is attributable in a great degree to severe wind-storms, which have blown the ripening berries from the branches, besides baring them, in many instances, of foliage. Pernettyas are negligible, and the inconspicuous berries of *Leycesteria formosa* are wanting. The exception alluded to is *Cotoneaster frigidus*, which is laden with its brightly-hued fruit, every tree being, alike, well covered. This variety succeeds here in a very exceptional way, and although a little ungainly in habit, it is certainly well worth its place in any shrubbery. *C. Simmonsi*, on the other hand, is not, during the present year, conspicuous. Among other shrubs notice may be directed to the fine effects produced by the ripening leaves of Azaleas. These range from a pale golden-yellow through various colours to a ruddy bronze. *Choisya ternata* increases in size year by year, its healthy growths giving indications of a fine display of bloom in its season. Pampas Grasses now lend their aid to brighten up the closing season. These fine and massive plants are well suited by the deep, rich, rather peaty soil in which they are grown, and increase in size annually.

Flower beds.—Like hardy plants, the more tender subjects of the flower garden yet go on unchecked. As there will be no spring bedding done, the continuation of the display is not unwelcome. Begonias have done better in their closing stages than was the case during mid-summer. These will be permitted to remain until the stems die, or are frosted down, when the tubers will be lifted and stored in Cocoa-fibre. *Salvia Pride of Zurich* is yet bright, and although *Antirrhinums* are pretty well over, yet there are stray tips of bloom. *Pentstemons*—of the Gem family—have made fine plants. It is intended, by way of experiment, to leave a couple of long beds over winter, observation having shown that, in the garden borders, two-year-old plants have always proved superior to those from the current year's plants. Again, the value of a good strain of *Ageratum*, as compared with *Heliotrope*, for summer bedding has been demonstrated. It is yet quite good, alike in leaf and flower, while *Heliotrope* is leafless and shabby. Some of these flower beds were rather interfered with by some large trees in their neighbourhood, but, during the week, those were felled, and it is hoped that their removal will prove of benefit in the course of the ensuing year.

Aloysia citriodora.—During the week some stock plants of the Lemon Verbena were potted up. The plant is practically hardy here, but it is just as well to have some reserve pieces in case of an exceptionally severe winter. Pots 8 inches in diameter were used, and the plants are, meantime, stored in a cold-frame.

Vegetable garden.—As a consequence of the continued mild weather, growth among green crops is yet maintained. This is not an unimproved benefit, because the same conditions which favour the growth of vegetables encourage the growth of weeds. When time permits, the hoe will be run through the quarters. The sun is now not sufficiently powerful to kill the hoed-out weeds, but, if uprooted, they will fall an easier prey to frost. Cauliflowers are now turning in moderately well. From inquiries made I find that some of my neighbours have, like myself, suffered from a partial failure of this crop; as a matter of fact, in one garden only two heads having been cut so far. Where Cauliflowers are, fortunately, plentiful, it ought to be borne in mind that frost is, probably, not far away, and preparations should be made for protecting them. Moderate frosts can be dealt with by breaking the foliage over the curds, or the plants may be lifted and laid in closely in a deep trench, where they can be protected by mats. Continue earthing up late Celery. Up till now earthing-up has been delayed by unfavourable weather, but now that conditions are more settled it is hoped to overtake this work shortly. W. MCGUFFOG.

Balmae Gardens, Kirkcudbright.

ROYAL HORTICULTURAL SOCIETY.

NOVEMBER 7TH, 1916.

IF, on the first view, the fortnightly meeting held on this date was apparently small, there was much of interest in the several departments, and more than one hardy plant novelty of importance staged. Chrysanthemums were particularly well shown. Nerines, too, were showy and in great variety, the large collection of frame-grown examples from Keston demonstrating greater hardiness—to say nothing of a much-enhanced utility—than many who would like to grow these plants can possibly be aware of. The display of *Gentianella* from Exeter was very fine and showed there is no dearth of that good plant's flowers in that district. Carnations, Begonias, Ferns, cut and pot-grown shrubs from more than one source, and a considerable showing of Orchids were also sources of interest.

HARDY PLANTS.

November is not the month for much in this department, yet the things that are, come as reminders of the wealth and procession of hardy flowers throughout the year. Apparently disdaining the frost, which put an end to all the Michaelmas Daisies, *Aster grandiflorus* was in good condition from Mr. Reuthe, though the species often suffers with the rest. From the same exhibitor came *Crocus ochroleucus*, *C. marathousius* (the finest white), and the mauve-coloured *C. Clusii*. The terminal spikes of *Buddleia auriculata*, with their white and pleasingly fragrant flowers, are distinct from many of its class, though, as shown, the plant did not suggest vigorous growth. *Fagus Cunninghamii*, *Pilostegia virburnoides*, and *Escalonia organensis* (rose-coloured) were also noted. The display of Nerines was very fine, and, as the result of frame culture, showed greater possibilities with these plants. A central display of *N. coruseans* was particularly good. Mr. G. Kerswill again showed the common *Gentianella* very finely, the brilliant colour of the flowers, as also their not inconsiderable numbers, a great attraction. Christmas Roses already in flower, *Viola* *La Clarkson* (a cornuta form of almost royal purple), and *Polyanthuses* were shown by Mr. G. W. Miller. From Messrs. Blackmore and Langdon came a small exhibit of the larger single-flowered Violets, *La France*, *Princess of Wales*, and *Ascania*, all highly desirable and distinct. To these has now to be added the new Governor Herrick, of reddish-purple tone with pronounced white eye. Alone it is handsome and good, but the colour does not harmonise with that of any of the others named.

HARDY SHRUBS.

Quite among the best novelties in this department were the new *Berberis Sargentiana* and *B. rubrostilla*, both of which merited the first-class certificates awarded them. That first named was shown by Hon. Vicary Gibbs, Aldenham House, Elstree (gardener, Mr. E. Beckett). An evergreen kind with leafage not unlike that of *B. Wallichiana*, it is effective now by reason of the green, copper, and scarlet of its leaves, and a bush of it in autumn is striking. In fine contrast are the outstanding ivory-white spines of an inch and a quarter long. The other sort named *B. rubrostilla* came from the Royal Horticultural Gardens, Wisley, and is, presumably, a hybrid, though the parentage was not stated. Deciduous and erect-habited, the elegantly-formed bush is freely branched and is now very ornamental by reason of the numerous ovoid, brilliant coral-red fruits, which, on slender pedicels, depend

from the gracefully arching branches. No hardy plant attracted more attention than these. Of particularly good colour, in the collection shown by Messrs. Waterer, Sons, and Crisp, were *Vaccinium pennsylvanicum*, *Quercus coccinea* (Waterer's variety), and *Acer palmatum septemlobum* (Bagshot variety). These afforded varying shades of scarlet, the last-named very brilliant. *Forsythia viridissima* (bronze, orange, and crimson foliage) and some *Azalea pontica* also gave good leaf-colour. In a like group from Messrs. J. Cheal and Sons *Quercus coccinea splendens* and *Berberis Thunbergii* were the best things, though some of the Azaleas and *Liquidambar styraciflua* also gave good colour-effect. Messrs. Piper showed a collection of shrubs in pots in which *Berberis nepalensis*, *B. japonica* Beali, *B. Wilsonae*, *B. brevipaniculata*, and other species of the genus were prominent. Quite one of the most attractive subjects staged in this section was the group of *Hakea encalyptoides* from Messrs. R. F. Felton and Sons. The leaves, shaped like those of the Mistletoe, though thrice as large, are thick and of a glaucous-blue colour, the globose flower clusters of cream and red appearing in the leaf-axils. Some examples bore buds and fully-expanded flowers. Others showed the mature fruits in their nut-like shells. The plant is of considerable ornament and is said to last well when cut.

GREENHOUSE PLANTS.

Begonia Mrs. J. A. Peterson, allied to the *B. Gloire de Lorraine* set, was among the best new plants in this department. The leaves are dark bronze, above which the crowds of rich carmine flowers are very striking. *Cibran's Pink* we consider one of the best winter-flowering *Begonias* ever raised, the colour good, the blossoms shapely and refined. *Bowden Beauty*, *Emita*, *Optima*, and *Scarlet Beauty* were others of note. These were from Messrs. Stuart Low and Co. *Begonias* of the *sempervirens* set were staged by Messrs. Blackmore and Langdon, *virginialis* and *Brilliant* being good among many. Some good Nerines came from Messrs. Barr and Sons, *Pink Beauty*, *Shelley*, *Vivid*, and Mrs. H. J. Elwes (deep coral-pink) being notable among many sorts. *Cerise* (of almost amaranth tone) was also distinct. *Primula obovata*, *Begonias* of the *Gloire de Lorraine* set, and a collection of choice Ferns were staged by Messrs. H. B. May and Sons, Edmonton. Both hardy and exotic Ferns were on view, and, apart from the choice forms of *Polypodium vulgare*, which were freely staged, we were struck with the beauty of *Polystichum aculeatum pulcherimum gracillimum* Drueryi, a rare form of high ornament, if heavily burdened with names. Nothing new was remarked among the many excellent Carnations staged by Messrs. Allwood Brothers, though the highly-fragrant *Bishton Wonder* has not before been seen in such good condition. *Benora* (white ground fancy) was finer than we remember it before, the large flowers showing well the clear white ground and scarlet markings.

CHRYSANTHEMUMS.

The finest group of these was from Messrs. W. Wells, Limited. Arranged artistically on the floor, representative of many sections of the flower, and backed by handsome Kentias, it looked its best. Three dozen blooms of the white-flowered *Louisa Pockett* (a big exhibition sort) occupied the centre, the foreground being set with a capital assortment of singles, of which *Gem* (white), *Crimson Velvet*, *Max* (reddish-chestnut), and *Supreme* (maroon-crimson) were among the best.

Yellow Jewel and *Cranfordia* were also good. Adjoining was a capital table group from Messrs. H. J. Jones, Limited, who arranged imposing stands of the best exhibition sorts throughout the group, with vases of decorative sorts in front. *Bob Pulling* (the best golden), Mrs. R. C. Pulling (rich yellow), *Frank Ladds* (golden yellow), and Mrs. Tofield (red) were among leading sorts, while singles and some of the many sports from *Caprice de Printemps*, *White Cap*, *Yellow Cap*, *Red Cap*, and others, were in the front. Messrs. Godfrey and Sons had an exhibit wholly of single-flowered sorts, many in spray form. W. J. Godfrey (the best pink), *Western Queen* (Anemone-flowered, pure white), *Reginald Godfrey* (apricot-bronze), and Mrs. Smollet Campbell (cherry-crimson) were some of the best in an imposing lot. The whole of these were raised from seeds sown in early spring, and as such represented a fine strain. Misses Price and Fyfe also showed a goodly lot of single-flowered varieties, including several of recent introduction.

ORCHIDS.

Of these, Messrs. Armstrong and Brown had a centre of choice things, none more chaste, however, than a finely-fashioned seedling of *Laelia pumila alba*. With it were *Cattleya O'Brieniana alba*, *C. Saturn alba*, and *C. Clæsiana alba*, richly-coloured *Odontodas* at right and left making a fine contrast. *Laelio-Cattleya luminosa* was very handsome. Several seedling *Odontoglossums* were on view, one of the best receiving a preliminary commendation card. Messrs. J. Cypher and Sons showed strongly of *Cypripediums*, *Queen Alexandra* (crimson and white), *Leeamum magnificum*, *Rosette*, *Sir Redvers Buller*, and *Gaston Bulteel* were some of a large collection. A superb *Cypripedium*, Mrs. Hilary Jenkinson, from Mr. R. Windsor Rickards, Usk Priory, Monmouthshire, gained a First-class Certificate, an Award of Merit being given to C. A. J. H. Smith, a pretty hybrid of the *C. niveum* set from Mrs. Norman Cookson, Wylam-on-Tyne. Fifty well-flowered examples of *Cattleya Fabia alba*, staged by Messrs. Sander and Sons, demonstrated the sterling worth of this autumn-flowering sort. *Cattleya Katie* and *C. Hardyana*, and the highly-fragrant *Trichosma suavis* were noted. *Sir Jeremiah Colman* sent from Gatton Park, Reigate, *Laelio-Cattleya Epicasta* variety *gloriosa*, *Cattleya Gatton Ruby*, and others. Two good forms of *Brasso-Cattleya Queen Alexandra* were in a group from Messrs. Charlesworth and Co. Of *Laelio-Cattleyas*, *Salonica* and *Numidia* were notable. A giant example with a freely-branched spike 5 feet or so high of *Odontoglossum Lambeauianum*, from Mr. G. W. Bird, Manor House, West Wickham, received a cultural commendation.

FRUIT AND VEGETABLES.

For an exhibit of fruits of *Diospyros Kaki* Voshonani, sent by His Grace the Duke of Devonshire, a silver Banksian medal was awarded, a like award being given to the Hon. Vicary Gibbs, Aldenham House, Elstree, for *Leeks* and *Celery*. The latter was in six varieties and of excellent quality, *Aldenham Pink*, *Aldenham White*, *Superb Pink*, and *Invincible White* were some of the best. The *Leeks* were *Prizetaker*, *Royal Favourite*, and *Improved Musselburgh*. All had finely-proportioned stems.

A complete list of the certificated plants and medals for groups will be found in our advertisement pages.

CORRESPONDENCE.

PLANTS AND FLOWERS.

Salvia patens (A. T.).—The plants should be lifted from the open ground, and, after the soil has been well shaken off the roots, be placed in fine, dry soil in a greenhouse or in a cold-frame, and be so far protected that frost shall not reach them. In this way the roots keep better than when dried and put away in sand or on a shelf. Plants in pots should have the stems cut down and be stood under a greenhouse stage till March. These, if brought into the light then, will, if watered, start into growth, and young shoots thus produced make fine cuttings, which should be rooted in heat and hardened off previous to being planted in the open air. The roots when hardened off may also be planted out.

Streptosolen Jamesoni (Mrs. Lawrence).—This is a free-growing plant of a shrubby character, which should be given much the same treatment as a Fuchsia, except that it must not be dried off to the same extent during the winter. It may be grown as a bush in the greenhouse, or trained up a pillar, while old specimens, if planted out during the summer, will flower profusely. The flowers when first expanded are yellow, but gradually deepen in tint till they become of a red-dish-orange hue. Though best known under the above name, it is by botanists called *Browallia Jamesoni*. When it has done blooming it should be cut hard back and encouraged to make an early growth, so that the wood may become well ripened during the summer, as the flowering to a great extent depends on the proper maturation of the wood. It requires a very light position in the greenhouse. The best soil for it is a mixture of loam, leaf-soil, and sand.

TREES AND SHRUBS.

Pruning Wistaria (Enquirer).—The Wistaria, when doing well, grows very strongly. Pruning should be done as follows: Soon after midsummer all the young shoots on the main stems should be pinched back to within a foot of the main stem. These shoots will again break into growth from the buds just behind where the shoot was stopped, and after growing a few inches they should again be pinched. This will cause the formation of flower-buds at the base of the shoot first shortened. The following spring these shoots may be cut back to within five or six eyes of the main stem, and the young shoots treated as above detailed. If there is any bare space on the wall which you would like filled, you can nail up one of the young growths, at the same time cutting it about half down in order to cause it to form flower-buds at the base. If your Wistaria is well furnished with flowering-spurs, which are formed at the base of last season's growth, the young shoots may be cut back in December to within two eyes of the flower-spurs. In this way they will develop more quickly when the sap begins to rise than if the long shoots had been allowed to remain. As regards the two other plants you mention, *Aristolochia* and *Virginian Creeper*, very little pruning is necessary, merely cutting out any of the shoots where they are very weak or too thick. The best place for them is a pergola or planted against a tree over which they can ramble at will. Name and address should always be given when sending queries. See our "Rules to Correspondents."

FRUIT.

Pruning Black Currants (R.).—As Black Currants bear on the wood made the preceding year, the proper course in pruning is to cut out some of the older growths, shortening back the young growths a little when they are unduly long or project much beyond the other shoots. It is the suckers from the base of the bush that one wants to encourage, and if they are too crowded it is an easy matter to thin them out.

Glou Morceau Pear cracked (Enquirer).—We should not destroy the tree. The cracking is due to a fungus known as *Fusicladium pirinum*, the remedy for which is to spray the tree with a wash containing sulphate of iron in addition to caustic soda, such as that designated Woburn wash. Do this as soon as the tree has been pruned and the ground cleared

of rubbish beneath it. Then before the buds burst, when the tree has flowered and the fruit has set, and again in from two to three weeks afterwards spray with Woburn-Bordeaux mixture. Use both insecticides according to the directions sent with them.

VEGETABLES.

Tomatoes failing (A. M. M.).—Did you renew the soil when you planted out the Tomatoes? Failure invariably follows if the plants are grown for two years in succession in the same soil.

MISCELLANEOUS.

Sawdust as manure (R. A. T.).—We should certainly hesitate to use the shavings and sawdust as manure, as they only promote the production of fungi. Use some of the sawdust on a separate piece of ground, and note the result.

Wood shavings (Sweet Briar).—These are the very worst things you can use when mixed with manure, as they only breed fungus, which destroys the roots of all plants with which it comes into contact. The only thing you can do is to clear out all the wood shavings and substitute some good manure. Lime would be an advantage also. For the wireworm, the best thing you can do is to dig in Vaporite or other of the soil fumigants now to be had. To destroy the mildew, dissolve an ounce of sulphide of potassium in two pints of hot water, then add enough rain-water to make 2½ gallons. Use a syringe with a very fine nozzle and see that the undersides of the leaves are thoroughly wetted. You can always have the numbers of the paper regularly from this office if you become a subscriber. We do not reply to queries by post, and cannot undertake to send a single copy containing an answer to a query as the reply is given in the hope of benefiting other readers who may be in a like difficulty.

SHORT REPLIES.

M. Thomas.—Your Apples were gathered too soon, hence the shrivelling. Fearu's Pippin is fairly late, and ought to have been left on the tree as long as consistent with safety.—**Miss Macdonald.**—The latest single-flowered Red Hawthorn is *Cratægus oxyacanthoides coccinea*, and the latest double-flowered variety is *C. Paul's Scarlet*.—**Middleham.**—See reply, re "Plums cracking," to "Amelia," in our issue of November 11th, page 574.

NAMES OF PLANTS AND FRUITS.

Names of plants.—**Miss Macdonald.**—*Berberis vulgaris* type.—**K. A. T.**—*Cratægus Azarolus*.—**Eleanor Pain.**—The plant is *Zephyranthes candida*, or "Swamp Lily," and belongs to the *Amaryllis* tribe, and not to the *Crocus*, as suggested.—**Donovan.**—*Bulbinella Hookeri* (syns. *Anthericum Hookeri* and *Chrysobactron Hookeri*). See "English Flower Garden."—**A. B. C.**—Quite impossible to name from the wretched scraps you send us.

Names of fruits.—**Anxious.**—Apples: 1, Rymer; 2, *Mère de Ménage*; 3, King of the Pippins; 4, Golden Spire.—**M. S. S.**—Pears: 1, Marie Louise; 2, Glou Morceau; 3, Winter Nelis.—**S.**—Apples: 1, King of the Pippins; 2, Cox's Orange; 3, Bramley's; 4, French Crab.—**L. S. H.**—Apples: 1, Alfriston; 2, Golden Noble; 3, Sturmer; 4, Northern Greening.—**G. S. Y.**—Apples: 1, Annie Elizabeth; 2, Wellington; 3, Lane's Prince Albert; 4, Red or Winter Hawthornden.—**T. D. L.**—Pears: 1, Beurré Bosc; 2, Catillac; 3, Beurré Claireau; 4, Souvenir de Congrès.—**G. R.**—Apples: 1, Fearu's Pippin; 2, Bess Pool; 3, Striped Beaufin; 4, Norfolk Beaufin.

Parcels sent to our office insufficiently stamped will, in future, be refused.

"FLORA AND SYLVA."—Copies wanted
Parts 1, 2, 3, 21. 2s. 6d. each offered for clean, perfect copies delivered at this address.—MANAGER, 63, Lincoln's Inn Fields, London, W.C.

LIST OF AWARDS AT THE R.H.S. MEETING ON NOV. 7, 1916.

ORCHID COMMITTEE.

First-class Certificate.

Cypripedium Mrs. Hilary Jenkinson, from Mr. R. W. Richards, Usk Priory, Monmouth.

Award of Merit.

Cypripedium J. A. Smith, from Mrs. Norman Cookson, Oakwood, Wylau-on-Tyne (Gr., Mr. H. J. Chapman).

Medals.

SILVER FLORA.—Messrs. Sander and Son, St. Albans; Messrs. Jas. Cypher and Son, Cheltenham; Messrs. Charlesworth and Co. Hayward Heath; Messrs. Armstrong and Brown, Tunbridge Wells.

FLORAL COMMITTEE.

First-class Certificates.

Berberis rustostilla, from R.H.S. Gardens, Wisley
Berberis Sargentiana, from Hon. Vicary Gibbs, Aldenham House, Elstree (Gr., Mr. E. Beckett).

Medals.

SILVER GILT FLORA.—Messrs. H. J. Jones, Ltd., Lewisham, for *Chrysanthemum*; Messrs. Wells and Co., Ltd., Merstham, for *Chrysanthemum*.

SILVER FLORA.—Messrs. Barr and Sons, Taplow, for *Nerines*; Messrs. Stuart Low and Co., Enfield, for *Begonias* and *Carnations*.

SILVER BANKSIAN.—Messrs. Allwood Bros., Hayward Heath, for *Carnations*; Messrs. Cheal and Sons, Crawley, for autumn foliage; Messrs. Godfrey and Son, Exmouth, for *Chrysanthemum*; Messrs. H. B. May and Sons, Edlington, for *Ferns*, etc.; Messrs. Eyer and Son, Bayswater, for *Chinese Berberis*; Mr. G. Reuthe, Keston, for *Nerines*.

BRONZE FLORA.—Messrs. Blackmore and Langdon, Bath, for *Begonias* and *Violets*; Messrs. Waterer, Son and Crisp, Bagshot, for autumn foliage.

BRONZE BANKSIAN.—Mr. C. Boatwright, Herne Hill, for *Aspidistras* and *Palms*; Mr. G. Miller, Wisbech, for hardy flowers.

FRUIT COMMITTEE.

Medals.

SILVER BANKSIAN.—Hon. Vicary Gibbs, Elstree (Gr., Mr. E. Beckett), for *Leeks* and *Celery*; His Grace the Duke of Devonshire, Chatsworth, for *Diospyros Kaki* Yshonani.

OUR ISLAND GARDENS.

THERE is no country in Europe where so many plants of garden value may be grown as in these islands of ours, giving us much of the cream both of northern and temperate climates, and good for vegetable growth as well as tree, flower, or shrub, as one may see who compares gardens in Britain with those in America or Continental Europe.

Take, as instances, Bicton, Caerhays, Fota, and many gardens in the south of Britain. One might think it was a question of the warm south, but it is not so, as we have that of Castlewellan in the north of Ireland, and gardens in the west of Scotland full of thriving things that would not live a season in midland places. Sir Herbert Maxwell, in *The Garden*, has been writing of one instance, showing how difficult it is to offer any ideas which will apply to all parts of our islands so varied in climate.

PLANTS AND ASPECTS.—Summer sunshine is tempered in the West by the humidity of the atmosphere, and, as a rule, the soil is more moist and cool than that of inland counties. Hence, while notes on the value, and in some cases the need, of a northern exposure for certain shrubs will prove most useful to cultivators in Midland and Southern England, they are not equally applicable to gardens subject to Western conditions. *Mutisia decurrens* is far more vigorous and flowers more freely here at Monreith against a brick wall facing south than another plant does facing north. *Berberidopsis* is now in perfect beauty on another brick wall facing south. *Tricuspidaria lanceolata*, *Lardizabala biternata*, *Solanum crispum*, *Escallonia macrantha*, *Tropæolum speciosum*, and *Azara microphylla* appear absolutely indifferent to aspect, the last-named, indeed, promising to attain the dimensions of a forest tree in the open. Cultural directions are not uniformly applicable to all parts of the kingdom. It took me some years before I learnt to accept under reserve such advice in plant catalogues from Southern nurseries as "grow in a moist, shady place," and to find that atmosphere is of more importance than aspect. For instance, *Trillium grandiflorum* is essentially a woodland dweller, but the sun of North America is far more powerful than that of Western Scotland.

The causes of these striking variations

in our climates are first a bold and broken coast-line and wide estuaries bringing the gentle breath of the sea inland. The sea itself is a great aid in our climate considered from the garden, as its genial influence is felt all round our long shores and sometimes far into the valleys that look seaward, and this sea-warmth gives a gain of two degrees over the warmth of inland hills near. It must be clear that this is a great gain to all who love the sea and shore.

Next, after the great influence of the sea we have to think of the effect of hill and mountain air, giving us some freedom from valley cold. There are many instances of the good influence of height on garden vegetation, such as Mrs. Chambers's garden at Haslemere, and Captain Acton's, in Wicklow and Mount Usher. Mountains in Ireland, Wales, and other parts offer these good conditions, but are as yet little taken advantage of.

On the other hand, the influence of midland and cool land is quite another thing, and there we have to avoid planting tender plants which may thrive in the same country on hill or shore. Between the low-level land and the hill there may be intermediate states not always easily understood, and so leading to mistakes.

The lesson of it all is understanding the varied conditions we have to deal with, to note the results of planting in the district we work in, being careful in the colder places to avoid disaster by planting tender trees and shrubs. W.

NOTES OF THE WEEK.

Wilson's Barberry in November.—This is now the most graceful dwarf shrub, with brilliant strings of fruit. Gathered for the house and placed in a Japanese bronze, keeping the form of the shoots, it is the best thing of the day. One or two sprays arrange themselves easily, as well as any Japanese artist in flowers.—W.

Campanula isophylla alba.—This has been lovely all through October on a sunny retaining-wall, where it is quite hardy in any ordinary winter.—NORTH LONDON.

Lageria alba in the open air.—May I submit for your opinion flowers of *Lageria alba* grown out of doors? The plant is in a narrow border, where it has been about four years. It has flowered each year since planted. It is trained on a trellis fastened to a wall facing north-east. The plant, which gets no kind of protection at any time, is now about 5 feet high and 5 feet wide, and has ten flowers look-

ing well considering the wet, windy weather we have recently had.—T. R. ELLIS OLVER, 7, Portland Villas, Plymouth.

[Judging by the handsome flowers sent, the plant is evidently quite at home.—ED.]

Fuchsia macrostemma, mentioned by Mr. J. Cornhill on page 554 of November 4th issue, I would not recommend to your readers. Here, in S.W. Surrey, it is cut down to the ground every winter, but comes up vigorously, producing much foliage, with a very scanty supply of pretty flowers, which are badly displayed, as the shoots are not upright.—S. W.

Sisyrinchium californicum.—The *Sisyrinchiums* are neat, attractive, little plants, with Grass-like foliage and little stary flowers on stalks a few inches long. In this species the flowers are larger than in most, and of a clear, deep yellow colour. It likes a sunny position in gritty soil, and is a very cheerful little plant. It can be divided up easily and can also be propagated from seed, which it produces very freely.—W. O.

Gaillardia Lady Rolleston.—I think the pure yellow forms, such as *Lady Rolleston*, far surpass the more gaudy ones in which red or crimson colouring predominates. The flowers of *Lady Rolleston* are very large and of a deep yellow with the eye of the same colour. It is a very free-flowering form, and, like most of the *Gaillardias*, is a good perennial in a light, sandy, well-drained soil. My plants were throwing up plenty of good blooms throughout October.—N. L.

Early signs of bulbs.—To-day (November 9th), while leaves were being raked along an avenue of pollarded Sycamores, my attention was attracted by the forward state of bulbs planted in the Grass under the trees. Snowdrops are exceptionally far advanced, and the various *Narcissi* are not much behind them. The mild weather and the excessive rainfall have, no doubt, something to do with this earliness, although I have noticed the same thing after a very hot summer followed by copious autumnal rains.—KIRK.

Buddleia asiatica.—This *Buddleia* is now (November 6th) a mass of bloom, and fills the immediate neighbourhood with its honey-like scent. It is said to be tender, but I have found it very free-growing, and it has never been injured by frost with me. A plant growing against a wall has overtopped it in a few years. Rooted cuttings planted in the open survived last winter. Like all *Buddleias*, it grows freely from cuttings. Though the creamy-

white blossoms are not showy, still this *Buddleia* is useful, flowering when there are few other shrubs in blossom.—S. G. P. HUTCHINSON, *Castle Lough, Nenagh, Co. Tipperary.*

Aster King of the Belgians.—This, belonging to the *Novi Belgii* set, gained an Award of Merit at the Royal Horticultural Society's meeting on October 10th. The flowers of the newcomer are large, and, while a distinct advance in this respect, its superiority is even more pronounced when the shapeliness of its flower-heads is considered. The colour is mauve. It is to the early set what *Climax*, at its coming a few years ago, was to the latest of these flowers.

Papaver rupifragum atlanticum.—This seeds about on a rough rock wall, with its pretty apricot-coloured flowers always welcome. Unfortunately, the blossoms are very short-lived, and lose their beauty by mid-day if it is at all hot. In the early morning, however, they are lovely, and, if picked quite early and brought indoors, will last well for a day, but not much longer. It is in bloom from April until cut off by frost in October or November. It seems of the easiest possible culture in dry, well-drained, gritty soil.—N. L.

Gentiana verna.—Whether this capricious little alpine has acquired parasitic habits or not, I agree with Mr. Hyde that it craves close company with some other lowly growth. I have found that it thrives well when grown with the smaller Stonecrops, such as *Sedum anglicum* and *S. Lydium*. *S. acre* grows too rank in soil of a quality to suit the *Gentian*. I am going to try the diminutive *Pratia angulata* or *repens* and *Mimulus radicans* as a carpet for it, though it is doubtful whether they will relish the lime, which is so congenial to the *Gentian*. *Noccea* (*Hutchinsia*) *alpina* is of suitable stature for the purpose, but does not spread so fast as the other two.—HERBERT MAXWELL, *Monreith.*

The weather in Kirkcudbrightshire.—One is surprised to read in Mr. Gallop's notes of the current issue (November 11th) of the early frosts of late October in Northants. Here no frost has yet been registered, and the foliage upon wall-trees is yet quite green and the usual time of pruning will be delayed. Dahlias yet are flowering freely, so, too, are Asters, and the later plants generally. *Tropaeolum tuberosum*, *Nasturtiums*, and suchlike plants, usually among the first to go, are yet unscathed, and such hardy annuals as *Nicotiana affinis*, *Lavatera trimestris*, *Godetias*, and *Eschscholtzias*, although now rather weather-beaten, are still flowering.—W. McG., *Balmac, Kirkcudbright.*

Lothian Stocks.—Those who may be, at the present time, cleaning up, ought to bear in mind that the usefulness of Lothian Stocks is by no means over. Many a lot of good plants, I have no doubt, is annually thrown out, when, had they been left, they would have given sheaves of bloom from March till midsummer. These Stocks are quite hardy, coming through all but the most severe winters with impunity. I have left plants for two years in hardy plant borders, that is to say, they have bloomed for three seasons before being dispensed with. In the case of these plants, however, I found that a percentage of them was apt to succumb if the winter was more than usually damp, or if there was a heavy fall of snow.—KIRK.

Begonias for planting out.—I fear "E. B. S." and "K. R. W." have rather misunderstood my note. I agree that tuberous *Begonias* are far superior, in every way, to Zonal *Pelargoniums* for

summer bedding. Nevertheless, the fact remains that in certain seasons they are what I described as "miffy." What I particularly meant, however, was that they are not adapted for cottage gardening. There, if anywhere, we expect to find more of the older perennials, *Roses*, *Tiger Lilies*, *Lavender*, and suchlike. Among these, *Begonias* are—at least, in my opinion—out of place. I know of one lovely old cottage garden which contained all the plants above mentioned, and more, which was ruined by a new tenant, who rooted out all the old plants, made what he called a lawn, and cut small, grotesque beds upon it. These, some 3 feet in diameter, he filled with *Begonias*, with edgings of *Lobelia*. He was both surprised and indignant when, at the annual competition, his "flower garden" was not even highly commended. One of the judges summed it up neatly as "a pale reflex of the garden of the neighbouring laird." *Begonias* are all very well in their way, and in their place, but there are many more suitable plants for the cottage garden.—KIRK.

Pittosporums in Co. Tipperary.—*Pittosporums* are not often seen in gardens, though they are fairly hardy and have all the good qualities of an evergreen shrub, except that the flowers are insignificant. In the case of *P. tenuifolium* (*P. Mayi*), *P. Colensoi*, *P. undulatum*, and *P. eugenioides* the foliage is striking, looks well all the year round, and is useful in the winter for cutting and mixing with flowers. The plants form shapely bushes, do not get bare at the bottom, and will grow in poor soil and in partial shade. Some bushes are thriving on a dry bank under a row of large Ash-trees, where few plants will grow. *P. tenuifolium* has grown over 12 feet high in seven or eight years. *P. eugenioides* appears to be the least hardy, as one plant was cut to the ground about five years ago, but it grew up again and is now 5 feet high. There is a variegated variety which is very handsome and which makes a good shrub for a wall. Cuttings of *P. tenuifolium* put into the open ground two years ago have rooted and survived 15 degs. of frost. Some small plants of *P. Tobira* were killed by frost a few winters ago, though it is said to be one of the hardiest, but larger plants survived. *P. undulatum* has ripened seeds, which germinated freely.—S. G. P. HUTCHINSON, *Castle Lough, Nenagh, Co. Tipperary.*

Hypericum patulum.—The variety of this fine shrub known as *Henryi*, having been introduced from China by Professor A. Henry in 1898, is superior to the original Japanese plant introduced by Oldham in 1862, in stature, in size and colour of blossom, and, it is said, in hardiness; but in one respect it must be pronounced inferior to the older variety. *Henry's St. John's Wort* flowers in July and August, making a very beautiful display while it lasts, but it is all over by the beginning of September. Oldham's variety, on the other hand, beginning simultaneously with the other, maintains a profusion of bloom until cut off by the first frost. We have escaped frost here so far, and this *Hypericum* is still putting forth quantities of flowers. I measured a plant this morning (November 7th), 6 feet through and 4 feet 9 inches high, a compact green dome studded with hundreds of golden blooms. I have compared the flowers with the beautiful coloured plate in the *Garden* of September 22nd, 1877, page 280, and can testify to its fidelity. It was that plate which first induced me to obtain the plant, and I have never been without plenty of it since, for it sows itself freely in odd corners. The *St.*

John's Worts are remarkable in this respect, that although in the wide range which they cover, extending from the mountains of Java close to the Equator, through temperate Asia, Europe, and North America, the different members of the family assume an infinite variety of forms. Only a single species has been found unfaithful to the hereditary golden hue of the petals, *H. leve rubrum* having hoisted a freakish orange-scarlet flag of its own.—HERBERT MAXWELL, *Monreith.*

FRUIT.

GUMMING OF FRUIT-TREES.

If it were always possible to trace everything to its source, it would be found that gumming in stone fruits in most cases had its origin in a deficiency of lime in the soil. Other causes doubtless may lead up to it, such as deep planting, or planting in too rich soil. Much injury is done by cropping the borders in which the choicer kinds of stone fruits are planted. The digging and manuring of the ground to meet the wants of the surface crops are sure sooner or later to throw the trees out of gear and bring on many evils, not the least of which is frequently a host of suckers, caused by the spade or fork injuring the roots, or by the manures which are used for the crops growing in the border. It is well known to most experienced cultivators that Peaches and Apricots do best in firm soil, but if the top spit is under spade culture, the roots must go down to a lower stratum for the firmness they need, and far away from the beneficial influence of solar warmth; the growth comes late and cannot ripen properly, and is more susceptible to insect attacks. And so a false step at the beginning may be the precursor to many difficulties later. It may be thought when a young tree is first planted, that as the roots cannot occupy all the soil the border may at least be used for something until the trees require it. This is plausible reasoning, and so early Peas, Potatoes, Tomatoes, and other crops are planted, the man with the spade goes to work, and the bad system once begun is continued. Again, very few think when planting young trees that it may be necessary in most soils to mix a little old plaster or lime in some other form with the soil, but to obtain clean, healthy growth, lime is an absolute necessity. Of course, on a chalk or limestone formation the natural soil contains sufficient lime for the wants of the trees, and those accustomed to note such things can tell by their appearance if the trees are getting their wants attended to.

DRAINAGE.—This is also very important. The Peach and Apricot are Eastern fruits, and a low temperature may be made still more hurtful if the drainage is not free. Perfect drainage is an absolute necessity if the trees are to do well. In cold soils with a clay base lift the borders up and mix some old plaster and charcoal dust or charred material with the soil in which the trees are planted. If the natural soil has a limestone base the consequences of deep rooting are not so noticeable: still, under any circumstances deep rooting is bad and in the long run will have injurious consequences, and for this reason alone Peaches and Apricots should have at least 5 feet or 6 feet of the border to themselves undisturbed. Most of us can call to mind instances where Apricots growing against the front or the gable end of a building, with the roots under a hard gravel path, have borne immense crops and were never troubled with gum or canker.

PLANTS AND FLOWERS.**ROOM AND WINDOW.****ROSE IRISH BEAUTY AND BLUE HOUND'S-TONGUE IN HOUSE.**

Both are very good plants. The Rose I have had for many years, and it blooms all the month of Roses. The other plant is a newly-bought annual flower, very easily raised, a constant bloomer, excellent as a ground-work among shrubs recently set out and the bare patches that often occur, and also good for flower garden work, the blue being a very good one.

W.

JAPANESE FLOWER GROUPING.

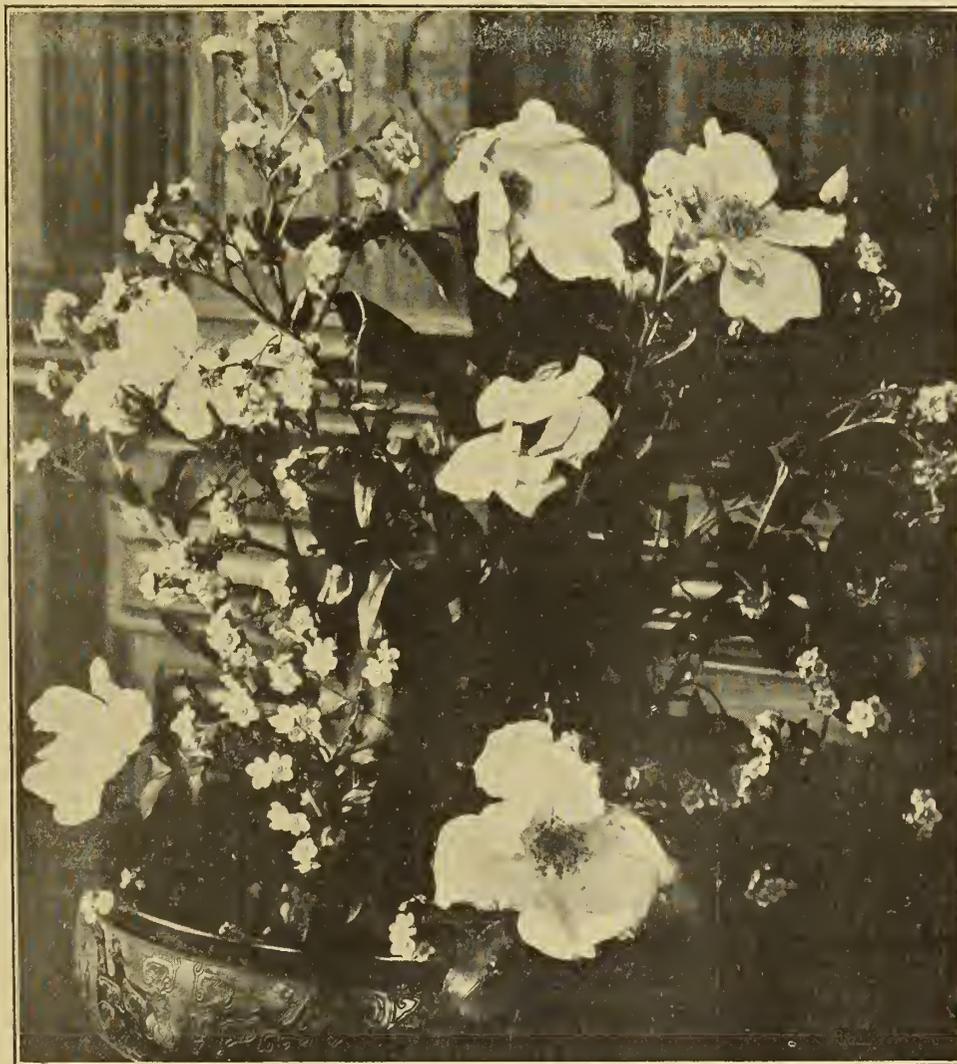

This, counted one of the essential parts of a Japanese girl's education, is very

natural branch or flower and place it in a vase, but subjects it to certain treatment, manipulating his materials as a painter would his colours, to form the design, according to traditional rules, which have to be carried out most faithfully.

GROUPING.—Very few flowers are used, but are perfect of their kind, as every small leaf or branch has its particular value in the composition of the picture; superfluous ones are clipped away to attain the desired effect. But perhaps the beauty, rather than the philosophy, of the flower art appeals more readily to the Western mind, though the designs show Nature in her active and passive moods. A creeper in one of their hanging Bamboos becomes a trail hanging over a cliff, shaken by the wind. A modest little Japanese

fully proportioned so as to give balance and symmetry to the group.

PREPARATION OF THE FLOWERS.—The different parts are carefully prepared before being put together, the right-sized flowers, buds, and leaves chosen, they are then cut to the right length, the bottom of Flag leaves sliced into a point, and stalks cleanly cut. To get a leaf to bend the right way it is damped and pressed gently over the hand. Japanese hands are soft and flexible, and the flowers seem to respond to their gentle touch very readily. Branches of Fir or Juniper, Bamboo, or flowering Plum are pruned, bent, and twisted into the right shape and curves for the desired effects. The parts being carefully prepared, a number of short pieces of stalks and leaves are cut into

Rose Irish Beauty and Cynoglossum in a bowl.

generally known among those of the better classes; there are a good many flower schools in different parts of Japan, one of the largest being at Kyoto, the ancient Western capital. The methods taught in these schools are lengthy, the instruction of a pupil can stretch over a period of five or six years, although to meet the requirements of the modern age these instructions are somewhat modified and curtailed, and a simpler course may be undertaken for a period of six months.

This art of flower grouping and arranging is in its graceful effects rather a linear than a colour study. It is undoubtedly a fine art, and represents a scientific study of Nature in grouping branches and blossoms to form a decorative picture. A Japanese flower artist does not merely take a pretty

group of water plants, in a flat stand, will give the effect of flags or reeds growing by the riverside in a way that a bouquet arranged in European fashion can never do. A Juniper, or Fir branch, properly fixed in a Japanese vase makes one think of a calm forest tree, whereas in an English one it may mean a piece of greenery, while their curved branches of Plum blossom fully convey the life and virility of a fruit-tree in springtime. The simpler arrangements of the groups are made in three parts—*shin*, or highest, *soye*, middle or support, and *tai*, the lowest or finish, which may be described as the equivalent of a picture composition, background, middle distance, foreground. In the more elaborate designs these divisions are increased to five or seven parts. These are all care-

corresponding numbers, about an inch long. The high vase, or stand, may be either of bronze or Bamboo, and across the top of it is fixed a short forked stick, in which the flowers or branches are placed in the right positions, the middle part leaning slightly either to the right or left—for Nature is never straight—and each leaf and flower is separated by a piece of short stalk, and this needs most careful handling. While the flowers are held in place with the left hand, the little pieces, or wedges, are slipped in by the right, and when properly made should be as firm as a growing plant. A loosened leaf or flower will spoil the harmony of the whole design, for to keep the right lines is most important. For the grouping of flowers in the low vases, or flat earthenware stands, heavy metal

separate stands, or holders, are used. They have little partitions in them, and are made in a variety of shapes and sizes.

SEASONS AND THEIR FLOWERS.—For a summer group of Iris fully-developed blossoms are used, and for a spring arrangement more buds. Dividing the leaves and blossoms into three parts, take the highest for the first division, those a third part shorter for the second, and for the lowest use a flower and leaves about half as high as the whole; the latter come into the foreground. The ends of the leaves must be cut to a sharp point, and other short pieces cut exactly to the height of the metal stands are slipped in firmly between every leaf and blossom as it is put in its proper position, wedging them in the stands as steadily as in the forked sticks. When placed in the dish little pebbles or stones are put in to conceal the stands, and when the water is added the effect is complete. Any water-loving plant may be used successfully for this style of arrangement. The water can be changed without any fear of disarranging the group, which will be found to last a long time, keeping fresh. Simplicity is the keynote of the Japanese taste, and where the English will have a dozen vases the Japanese will have only one, but that one, placed in the *tokonoma* or alcove of the room, will, as well as the flowers it holds, be perfect of its kind. It will generally be a flower of the season, as for decoration each season has its special flower, beginning with the Plum (*ume*), which comes into bloom at the end of January and lasts till March. The middle of April sees the Cherry (*sakura*) in full bloom, followed hard by the Azaleas (*tsutsuji*) on the mountain sides and garden banks. The Tree Pæony represents the month of May, at the end of which the Wistaria comes into bloom. The Iris and Lotus and the Convolvulus come in full summer; the glowing Maples and Chrysanthemums finish the floral season.

SYMBOLISM.—Colours have their values in Japanese flower grouping also, and red, which represents the male, and white for the female, are the suitable flower colours for a wedding. The mourner's colour in Japan is pure white. Purple is forbidden, and certain flowers, Willow branches, and plants are considered unlucky. The heads of Daphnes and Camellias fall off too easily to please the ancient Japanese. Pine-trees and Bamboos represent longevity.

Floral design, as understood in Japanese painting, when known more generally to the Western schools exercised a wide influence in them, and possibly their flower art would bring its teaching to bear upon our floral arrangements, were its methods better known among us here.—*The Times*.

WINDOW PLANTS.

VIOLETS IN POTS.—Probably very few ever think of growing Violets in pots, but it is one phase of culture which may afford much pleasure. I do not remember having seen Violets in windows, where, during the winter months, they would be even more happy than in frames, and, if properly grown, would flower to a certain extent during the dull months and would bloom abundantly in early spring. Half-a-dozen Violet blooms will diffuse a fragrance which is very pleasant and refreshing in the dwelling. I have grown the Parma Violet in this way and used the plants for conservatory decoration, and on entering the house in early morning the air seemed full of fragrance. The plants must, however, be thoroughly well grown so that plump crowns are secured. Growing the plants in pots all the summer will not do. I have tried this plan, but the Violet must have a free root-run in

rich soil during the growing time and be put into pots at the end of October, when the crowns are fully plumped up. Let them stand in the open until the end of November, so that they strike root again before taking them in. Never put them into a constantly-heated room, or they will become so weakened that the few flowers produced will be malformed and poor in colour. Let them stand in a cool room where air is given in mild weather, as this is absolutely necessary. In this way they will bloom as well as if wintered in frames, and they will be more secure from damp. Those fine double varieties, the Neopolitan and Marie Louise, can be had in good condition in this way, and Princess of Wales, considered to be the best single, is of easy culture.

FUCHSIAS will be quite out of bloom and will have ripened their wood, but they must have water when dry to keep them plump. If they suffer in the resting time from over-dryness at the roots they will not start so freely as they should do the following spring. Fuchsias at rest are not very attractive, and are apt to be neglected when the leaves have fallen, but this will not do if it is expected that they are to start strongly into growth the following year. It will not hurt them to get dry in late autumn and through the winter, but they must not become dust-dry or the tissues will shrivel to a certain extent, which is not seen at the time, but the effects of which are perceptible in early spring when they are pruned. No one cares to keep plants denuded of foliage in the windows, so that the Fuchsias have to take a back seat until growing time comes round again. From November up to March they may be stored in any out-of-the-way corner, only, as before said, they must not become too dry. I have known good-sized plants stored in an out-house. In very cold weather they were laid on their sides and covered with litter. In order to economise space they may be pruned moderately, but not back to the old wood, as this might cause them to break prematurely.

BULBOUS FLOWERS.—No time should be lost in potting up any kind of bulbous flowers that are so useful early in the year. There are, apparently, no Hyacinths to be had, but there is a wealth of Tulips, Narcissi, Crocus, Scillas, etc. Pot them in nice, free soil with a fair amount of drainage, and let them stand in the open until wanted.

BYFLEET.

FERNS.

FERNS IN HANGING BASKETS.

DESPITE the trouble which is involved in watering and attending to Ferns in hanging baskets or similar receptacles, they are always ornamental and interesting, and they tend to take away the bare appearance of roofs or of rafters upon which it is not considered advisable to grow the orthodox climbing plants. Baskets made of galvanised wire of a good gauge, and fitted with chains for suspending, are perhaps the best. These, lined with Moss and filled with the ordinary compost used for the particular variety to be grown, will prove very satisfactory and durable.

There are certain forms of Ferns which are peculiarly adapted for the purpose under notice. Chief among these are the Davallias, one of the finest for basket-work being *D. bullata*. Others of the family well adapted for hanging baskets may be found in *D. Mooreana*, *D. fijiensis*, and *D. canariensis*. The long, trailing growths of *Lygodium scandens* are seen to advantage when employed in this way, and *Cheilanthes hirta*, Ellis's variety, is much better grown in a basket than in a pot.

Many of the *Nephrolepis* tribe are excellent as suspended plants, none more so than the old *N. tuberosa*. Another good variety is *N. davallioides furcans*, while *N. exaltata* and *N. Fosteri* are almost equally good. *Adiantums*, too, may be used, including, as well as the familiar *A. cuneatum*, such sorts as *A. concinnum*, *A. Williamsi*, and especially *A. amabile*. I have seen *A. Farleyense* used as a basket Fern; but it requires stove heat, and even so is apt to suffer either from the rays of the sun or from incautious ventilation, unless particular attention is paid to its requirements. Very seldom met with in collections of present-day Ferns is *Hypolepis distans*. This pretty variety is a gem either in pots or in hanging baskets. For very large baskets, *Phlebodium aureum* or *Goniophlebium subauriculatum* may be employed with satisfactory results. Certain of the Spleenworts, notably *Asplenium rhizophorum* and *A. longissimum*, are very effective, especially the former, with fronds nearly 2 feet long. These, if pegged down, produce a very fine effect. *Polypodium Lingua* is hardier than many of those above enumerated, and may be used freely in a somewhat cool house. Most of the varieties named will do in the atmosphere of the greenhouse or conservatory; but in no case should they be too freely exposed to strong sunshine, and, above all, they must be regularly and liberally supplied with moisture. When established, if occasional supplies of liquid-manure or of chemical fertiliser in solution be given, the need for over-hauling annually does not arise, and the baskets increase in beauty year by year.

KIRK.

INDOOR PLANTS.

FUCHSIAS.

I HAVE not been to the London exhibitions for some years, and therefore do not know if big specimen Fuchsias are still exhibited. I have seen no mention made of them in recent years, so I suppose that they are not in favour nowadays. They have, I imagine, gone the way of the monster Cape Heaths and New Holland plants, which were some thirty to forty years ago such a prominent feature at the London exhibitions and some of the biggest provincial shows. These big specimens were marvels of high culture and always attracted a lot of attention. The cuttings were taken as soon as they could be got from plants placed in gentle warmth early in the year. Many a time when a young man I have looked at these plants and wondered how specimens 5 feet high, and correspondingly broad, perfect pyramids of floral beauty, could be produced in so short a time. Such plants have a very different appearance from the two or three year old specimens that one usually sees in private gardens. The power is not given to everyone to produce such large plants, and it is quite certain that there must be the convenience for doing so. I cannot say exactly how they were grown, but I should not wonder if in their earlier stages they had the advantage of mild bottom-heat, such as is afforded by leaves and dung. It is not only the stimulus to the roots which this mixture imparts, but atmospheric conditions are created which the Fuchsia loves and which have in some way to be created if plants of high excellence are desired. Those marvellous plants in 6-inch pots which are to be seen in Covent Garden Market could never be produced unless special means were taken to give them the atmospheric conditions in which they delight.

Market men do not mix things. They

never have more than one kind of plant in a house, and as their energies are concentrated on the few things they cultivate they naturally are able to bring them to a higher degree of perfection than the amateur who has perhaps a score of things all differing somewhat in their requirements, and has only one house for them. Without saying that the amateur can quite rival the market grower in perfection of growth it is certain that he may produce plants which would not compare unfavourably with them. In an ordinary greenhouse, and in company with Zonal Pelargoniums and other similar things, I have grown plants which would not discredit a market grower, but they got a lot of attention. The market men grow their plants in span-roofed houses, where the conditions are much more favourable than in the lean-to structures generally seen in small and medium-sized gardens. Fuchsias love a moist, genial atmosphere in the later hours of the day

is of supreme importance—*i.e.*, maintaining the soil in an equable state of moisture. In market gardens the plants, when growing freely, are sometimes watered six times a day, and whoever desires great excellence must not grudge labour. Better fewer plants and better quality.

BYFLEET.

NOTES AND REPLIES.

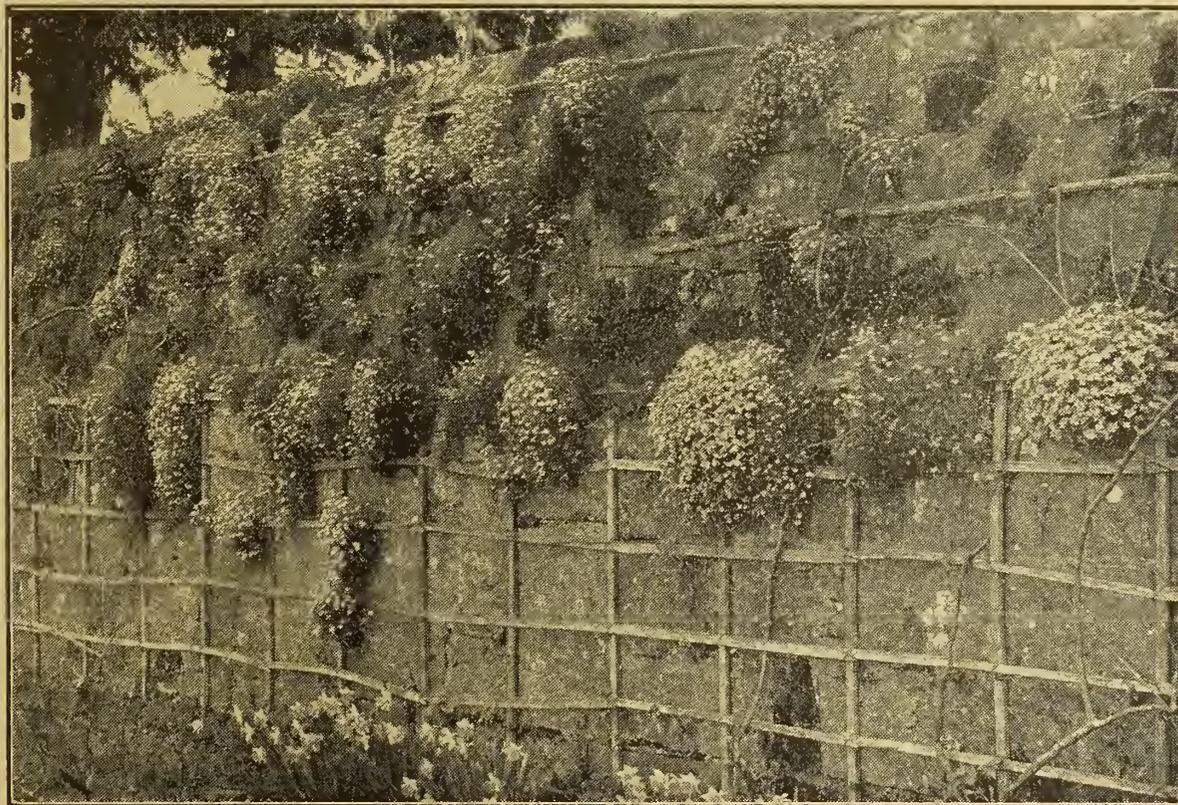

Fumigating the greenhouse—past and present methods.—Older readers will recollect the primitive methods of dealing with insects under glass by means of Tobacco-paper and rag fumigants. The introduction of the liquid nicotine that is vaporised over a spirit-lamp marked a great advance. Those of us who remember the old-time fumigants hailed this with considerable satisfaction. This vapour fumigation now has another competitor in "sheets" and "shreds." Nico-brand, supplied in small sheets, is a most convenient and labour-saving provision; so

the several modern preparations of nicotine now to be had it would seem a matter of choice as to which is the best. The aim in each case seems to be a minimum of cost with a maximum of value.—W. STRUGNELL.

ROCK, ALPINE, BOG, FERN, AND WATER GARDENS.

ROCK CRESS (AUBRIETIA) ON OLD WALL.

This cut shows an old sandstone wall upon which the purple Rock Cress has sown itself. There was one plant near the top of the wall from which the seeds scattered themselves over the wall. It need hardly be said that the effect is very good, and very welcome in early spring. It also shows how many old walls and buildings might be adorned by simply scattering a few seeds of the plant over them. It is simply the ordinary old kind of Rock Cress,

Purple Rock Cress on old garden wall, Gravetye.

and at night, and in order to ensure these genial conditions the last watering is given late in the afternoon, the house well damped down, and the plants well syringed. If your readers could see a house of Fuchsias when in bloom and ready for market they would be surprised not only at the quality of individual plants but their general condition. They are bloomed in 6-inch pots and are so arranged that by the time they come into flower they touch each other and form a solid mass of bloom, the plants being so evenly matched that one is the counterpart of the others. This perfection is, of course, only to be attained by years of experience and special convenience. These conditions can to a certain extent be imitated in the amateur's greenhouse. The Fuchsias should be placed together at one end, where they can get special attention in the way of syringing and shading lightly in very hot weather, for they are apt to suffer in lean-to houses during periods of great heat. One thing

simple and yet so effective in dealing with the various insects. The manufacturers claim that both red spider and mealy bug succumb to this nicotine preparation, but my experience has not borne this out. Green and black fly can be destroyed, and the Tomato fly succumbs to its deadly fumes. All the apparatus needed is a stake or a piece of wire, on which to hang the sheet, which may be broken into sections to suit small or large structures. The vendors claim that a match is all that is necessary for lighting, but I have found a wax-taper or a lamp much better. The lighting of the sheet is expedited if torn here and there on the edges. There is no possible risk of harm to plant life, because the sheets will not flame and no attendance is required. In shred form it has been on the market for some time. These shreds need only to be put down in small heaps, and, when lighted, no after attention is required. The strength of this preparation is such that but a small quantity is required at a time. As to the efficiency of

which varies very prettily. It may also be noted that there was no soil at all between the stones, and that the only nourishment for the plants is from the decayed lime, if that be any nourishment.

THE SANDWORTS (ARENARIA).

It must be sixty years ago that *Arenaria* (then termed *Spergula*) *caespitosa* seemed likely to occupy an important position in gardens generally. I cannot remember, for I was only a boy at the time, where or with whom the idea originated of using this Sandwort as a substitute for Grass, but I do remember the varying opinions expressed by gardeners on the occasion of our local flower show. The experiment, which seemed to promise well at first, was, in the end, a dismal failure. The hot weather browned it and the damp of winter finished it. As a fact, this species, free-growing though it may be, is liable to die off in some soils. It suffers from dry heat when much prolonged, and the delicate roots will assuredly suffer if the soil

becomes at all close in winter. Its needs are, however, easily met, a light, rather gritty soil, occasional waterings in the most trying time, and, where possible, shade during the hottest hours of the day fulfil its requirements. In the full glow of healthful vigour this Sandwort, planted thickly, makes a charming carpet, and one is not surprised that it should have been considered worthy of employment in the way above-mentioned.

A. BALEARICA is one of those things that may find a happy home in any garden, however small, and will rejoice in conditions inimical to the majority of hardy plants. In any dark, very much shaded corner it will grow luxuriantly, and only give it a big stone or a bit of old wall to ramble over and it will be as happy as any hardy plant can be. It is a delightful little thing, this Sandwort, and when the rich green foliage is lavishly besprinkled with the little starry blossoms it has a very pleasing effect. With me it has taken possession of an old brick edging in a semi-shady position, and now (in November) the attractive shade of green is even richer than was the case in early autumn. The finest member of the family, however, from a decorative point of view, is

A. MONTANA, and were I restricted to a score of rock plants this would be one of them. It has every quality that a rock plant should have, without any of the defects which detract from the usefulness of some alpine plants. It will thrive in any free soil, extends with freedom, and, what is very much to the purpose, does not need the watering-can. Plant well and leave it alone, and so long as it gets plenty of sunshine and air, and is kept free from weeds, it will yearly increase in bloom-bearing power. When covered with its large white blossoms, so abundant that they nearly hide the foliage, it is, in the form of a large specimen, most telling. It should be planted well up on the rock garden, and looks best when drooping over a big stone. Can any of your readers say whether there are two forms of this *Arenaria*? I think that they must be identical, as in some trade growers' lists it is given simply as *A. montana* and in others as *A. montana grandiflora*. If there are not a typical form and a larger-flowered variety the varietal term *grandiflora* is certainly out of place.

A. PURPURASCENS is not so showy and not nearly so vigorous as the preceding, but displays a quiet beauty that pleases.

A. TETRAQUETRA is the aristocrat of the family and an alpine of the first water. It is not of difficult culture, but resents neglect in any shape or form. Unless well cared for it is apt to die off suddenly.

J. CORNHILL.

NOTES AND REPLIES.

Primula cortusoides.—This is useful for a cool place in the rock garden and is of very easy culture in any light soil with plenty of leaf-mould incorporated with it. I mix mortar-rubble with the soil, but I do not think this is essential, although many *Primulas* seem to appreciate it. It seems to be constantly in flower and is always welcome. There are many different colour-forms. It ripens plenty of seed, from which it can easily be raised, and it is also readily increased by division. It was flowering with me right into November.—N. L.

Half pots for alpenes.—"Cecil A. P. Osborne," who inquires about half pots, so useful for many small alpenes, can get them in all sizes from Mr. William Branton, Linslade, Leighton Buzzard, Beds. I use a great many of them.—CHAS. OAKFORD, *Mells Park Gardens, Frome.*

VEGETABLES.

MILDEW ON ONIONS.

SOME amateurs strew short manure along the rows of Onions when the plants are from 4 inches to 5 inches high. The grower off whose ground I sent you mildewed specimens in 1915 did this, with the result that his Onions were attacked with mildew and maggot, and the whole went bad, row after row. It stands to reason that when a wet season sets in it must make the young bulbs sodden, and, therefore, cause them to decay. I have seen it done repeatedly. Ground well prepared before sowing certainly does not need it. In my twelve years' experience I have had neither maggot in my Onions nor had them attacked by mildew, the only overhead dressing they ever get being soot from the flues. I start this immediately they appear above the ground, even before the "loop" allows the stem to come to the perpendicular. I never sow without giving a dressing of soot, neither do I plant out any of the Cabbage family before dipping the plants up to the "collar" into a puddle of thick soot and water, and club-root is unknown to me, heavy clay soil though mine is. I have never bought a pennyworth of artificial dressing (manure, guano, or pest-killer) in my life, and, what is more, do not intend to while I can get the matter to dig in for the roots to feed on, and leave the rest to the hoe and Nature. My idea is that soot is the finest thing for preventing pests in the vegetable garden, putting everything underneath for the succour of the plants. This year I grew over 80 lb. of Shallots from rather under 9 lb. of seed-bulbs, with never a maggot in the whole, and employed nothing but soot after planting. As soon as the green shows I start dusting, and all has been well. The same thing obtains with Broad Beans and Runners immediately they are "up." R. S. W.

SCOTCH POTATO CROPS.

DISCUSSING the Potato yields and prospects, a correspondent in the *Yorkshire Post* states that the average crop in Scotland is about four tons to the acre, against an average in 1915 of about 6½ tons. The largest acreage of any variety was the King Edward, which divides popular favour in North Britain with the Arran Chief, a larger acreage than in previous years being planted with the Chief. It is undoubtedly the best Potato in Scotland, and has yielded very good crops where grown on loam or light land. British Queen has also been extensively cultivated north of the Tweed.

The comparative failure in weight of tubers in Scotland this year means that the merchants in Glasgow and the other principal markets cannot find sufficient satisfactory samples of good ware in Scotland to meet the requirements of their trade, and we find for the first time for many years English Potatoes selling in Glasgow, Edinburgh, and Leith, at prices obviously remunerative to the English grower. Ireland, too, where the crops in the main are abundant, is exporting to Glasgow, quotations for good Irish ware Potatoes being £6 10s. f.o.b. at an Irish port, equivalent to about £7 in Glasgow.

Supplies have gone from Cambridge-shire and the Midlands, as well as Ireland, but Yorkshire is placed in an especially favourable position for the Scotch market, by reason of the splendid samples grown there and the shorter railway journey. There is an abundance of seed in Scotland, the majority of the produce being of seed size, and if the merchants in Glasgow and the other markets can con-

tinue to draw ware supplies from England and Ireland they will decline to purchase Scotch-grown Potatoes. Therefore, the native farmer will have to find an outlet for his produce for seed purposes in England, after supplying his own needs.

NOTES AND REPLIES.

Growing Leeks in trenches.—Many people are disappointed in growing Leeks for the reason that they omit two important points in their culture, viz., a long season of growth and liberal treatment. Too many, I fear, are content with sowing seed in March and planting out in soil that cannot, by the widest stretch of imagination, be termed rich. The result, obviously, is spindly plants lacking that vigour which characterises those well grown. To have thick, blanched stems, one must be prepared to do them well, and to this end seed should either be sown in a cold frame in the autumn (which I regard as the better method) and planted out in April, or from seed sown in heat in February, subsequently hardening the plants and getting them out of doors. The old plan of dibbling a hole and dropping the young plants in is gradually being superseded by getting them into trenches previously well prepared, as for Celery, and, like Celery, earthing up. Leeks are so useful, and may be left in the ground until actually wanted for use, that every effort to bring them to table in the best condition should be tried.—DERBY.

Storing seed Potatoes in bags.—For some years I have stored my maincrop seed Potatoes in bags, and for some reason there seems less activity of the eyes, and, consequently, less attention to removing the growing shoots in winter is necessary. I do not mean to say the eyes remain latent until planting time comes round, very much depending on storing space. A cool shed is an essential even for storing them in bags, and so long as frost is kept off, the cooler one can keep them the better. I cover the bags with hay or straw litter—bracken is better when procurable—when the weather becomes threatening, and this is removed directly mild weather returns. Storing space, too, being limited, I have found storing in bags an advantage, as the bags can be piled up one above another, if need be, in any dry, covered shed. The bags being porous admit air pretty freely, and the bulk not being considerable, air can reach the tubers, hence, presumably, the reason why they remain less active in the bags. In the winter the tubers will need to be overhauled, and, after removing the forward shoots, returned again to the same receptacles unless other and more favourable conditions offer themselves. The direct advantages of bag storage would be found by those whose space is limited.—W. S.

Parsnips.—Complaints were rife last spring that Parsnip seed failed to germinate. This may be due to its having been badly harvested or to the fault of the season, but the majority of cases occurred in fresh ground, which, through shortness of time, was not properly prepared. Instances came under my notice where seed started well, and then in August, after a spell of dry weather, the plants deteriorated, a further source of trouble being the fly, which infested the foliage. To have good Parsnips, ground heavily manured the same season should never be selected, as such is apt to produce forked roots. It is essential that the soil should be well trenched, and if this can be done to a depth of 18 inches and a good layer of dung placed at the bottom it will help the plants in early autumn. No other manure need be applied, but if the ground is at all deficient of lime it will be found profitable to give it a dressing.—TOWNSMAN.

TREES AND SHRUBS.

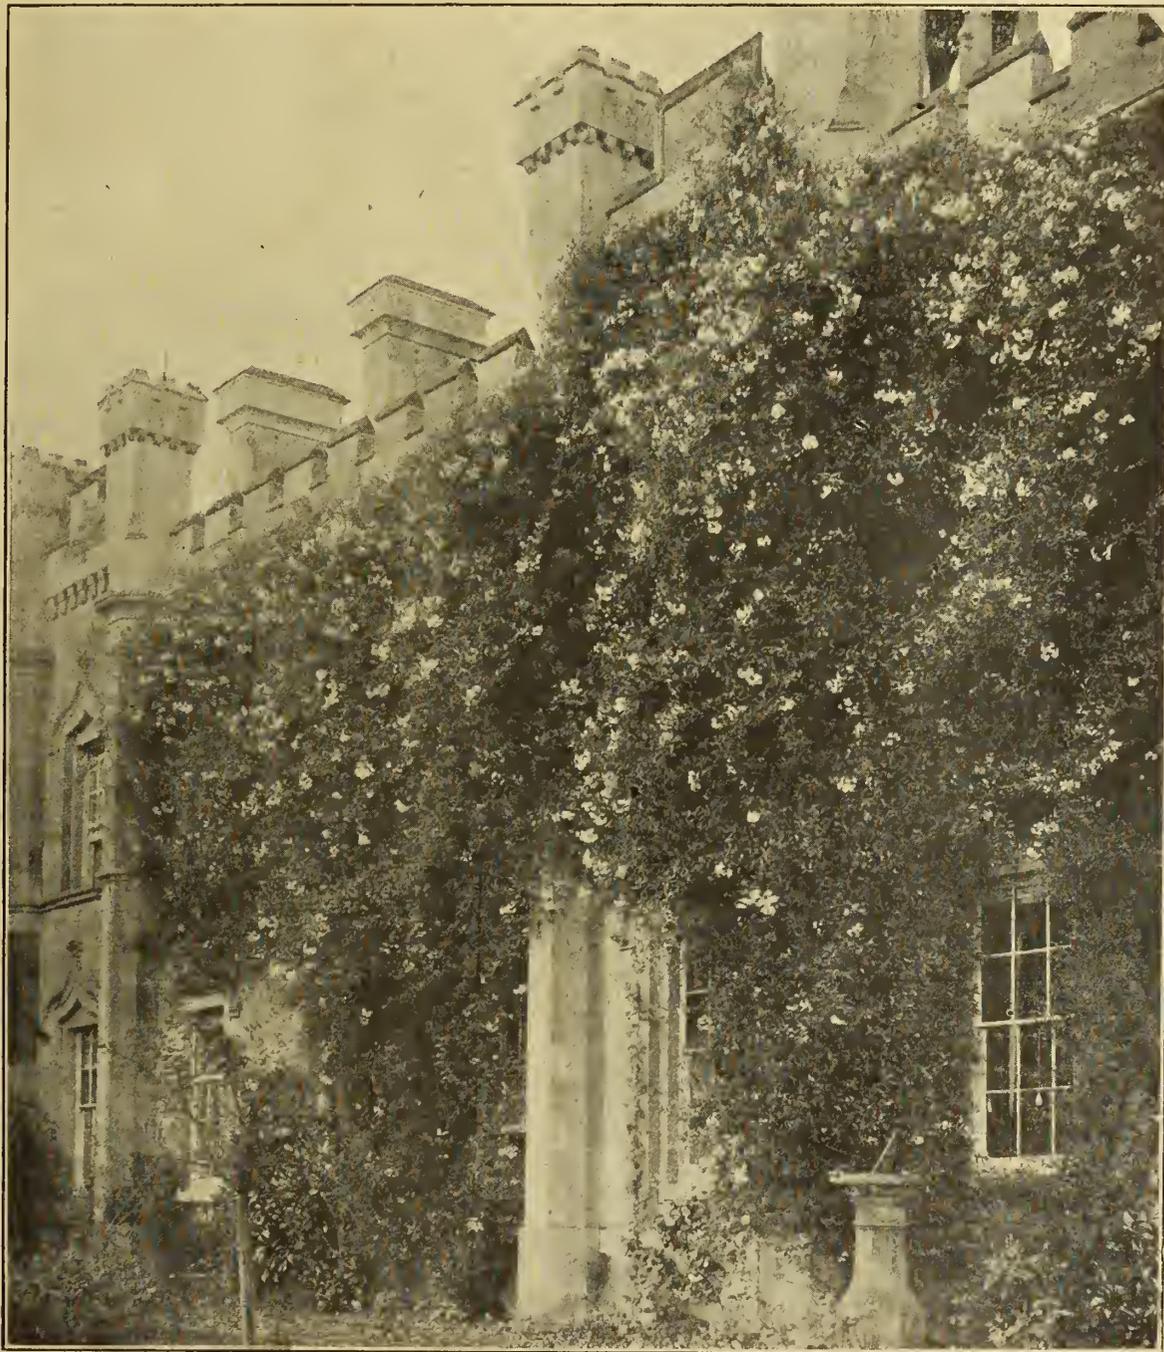

SOLANUM JASMINOIDES.

This is the finest example of the growth of a noble climber that we have ever seen. Long familiar to us as it is in the West Country and in gardens in the home counties, where it has a fair chance, it is not often grown so well as it deserves to be. The culture is quite simple. In this par-

mental evergreen shrub that reaches a height of 5 feet to 6 feet. The dark green leaves, supported by reddish stalks, vary a good deal in size, the largest being about 3 inches long and 1 inch in width. The flowers, which are of a clear rosy-red colour and nearly $\frac{1}{2}$ inch across, are produced in densely-flowered terminal panicles. Where not perfectly hardy it is well worth the protection of a wall, especially as the blossoms are borne at a season when most flowering shrubs are past. It

nearly white in colour. It is said to have been raised in the nursery of Mr. Robert Veitch, of Exeter, as the result of a cross between *E. pterocladon* and *E. rubra*.—K. R. W.

Light from an Oak.—Many of the peasant class in Spain make use of the bark of the Cork Oak to light their cottages. The bark is placed in a kettle, and when it is hot enough it gives off a gas which burns brilliantly. The lighting is not expensive, and the peasant saves the carbonised cork refuse, for he can

Solanum jasminoides on house at Sheffield Park, Sussex.

ticular case there is a stone footpath very near the border where it grows, and perhaps this helps the plant.

NOTES AND REPLIES.

Escallonia organensis.—This very distinct and uncommon species of *Escallonia* has been several times shown at the autumn meetings of the Royal Horticultural Society. Though more tender than some other species, it forms, in the favoured parts of these islands, an orna-

was introduced in the 40's of the last century, but had been previously discovered by Mr. Gardner in the Organ mountains of Brazil. A mistake has before now been noted in the name being spelt *oregana*, thus suggesting that it is a native of Oregon, but, in reality, its specific title is derived from the range of mountains where it was first discovered. Another *Escallonia* just now flowering freely is *E. exoniensis*, a hybrid shrub or small tree with terminal panicles of flowers white or

sell it, as it is known as "Spanish black," one of the intensest black-browns known among pigments.

Vitis inconstans.—Now that the foliage has fallen, let those who grow this rampant creeper upon the walls of houses give an eye to it. The plant will invade water-pipes, get under slates, and, in fact, take every opportunity of encroaching. If not regularly kept trimmed in such neighbourhoods as those referred to, the grower of the plant will find that he is laying up trouble for himself in the not distant future.—KIRK.

CHRYSANTHEMUMS.

NEW CHRYSANTHEMUMS.

J. H. BLYTHE (Japanese), bright chestnut, very handsome; CORDELIA (Anemone-flowered), fawn and bronze with yellow tipped centre; THORA (Anemone-flowered), rose, yellow centre. Shown by Messrs. Cragg, Harrison, and Cragg.

THOMAS BODMAN (Japanese), rich crimson, gold reverse. Shown by Mr. W. Baxter.

SHIRLEY GOLDEN (Japanese), deep rich yellow, said to be a sport from William Turner, one of the best exhibition varieties. From Mr. H. Woolman, Shirley, near Birmingham.

MRS. ALGERNON DAVIS (Japanese), of the drooping type and of refined deep lilac. Handsome variety of exhibition standard. From Mr. Norman Davis.

MRS. W. SMITH, a pure white exhibition single of high merit. From Mr. A. Robertson.

ALICE JINKS (Japanese), ruby-crimson, very handsome. Shown by Mr. Walter Jinks.

ALICE BENSON (Japanese), pure ivory-white, very handsome; GOLDEN WEST (Pompou), rich yellow; MARY (Pompon), deep orange-gold, of good form and colour; and BABY FELTON (Pompon), of almost amaranth colour. These were shown by Messrs. W. Wells, Limited.

EDITH DIMOND (single), golden-bronze, a fine decorative sort. From Mr. Phillip Ladds.

Each of the above received a first-class certificate from the National Chrysanthemum Society when shown on November 9th, 1916.

PROPAGATING CHRYSANTHEMUMS.

I SHOULD be grateful if you would tell me how and when to take good Chrysanthemum cuttings from indoor plants, or refer me to a book (not too expensive) which deals with the subject.—E. H.

[Many growers get these in during the latter part of November and the succeeding month, but it is doubtful whether much is gained by making a start before the New Year. Provided the old stools have been given a light position while in flower, and since been cut down, stronger growths will be forthcoming by the first or second week in January than would have been the case at the earlier period mentioned. Exception may be made in growing for exhibition, especially large blooms, but for ordinary decoration January will be found a suitable date. Comparatively cool treatment is the best for Chrysanthemums except while in flower, when a little artificial heat is generally necessary, as a preventive to damping of the flowers and mildewed foliage.

Many are the methods employed in rooting the cuttings, close cases or quite small garden-frames being stood in a lateinery, Peach-house, or an ordinary plant-house, where a little heat can be turned on in case of severe frost, while others rely upon quite cold-frame treatment in the warmer counties, where long spells of frost or heavy falls of snow are of rare occurrence. Strong cuttings are best placed singly in pots 1½ inches or 2 inches in diameter, keeping the cutting in the centre, while weaker ones, four in number, may be set around the side of a 3-inch pot. Sucker growths should be given preference when 2½ inches or 3 inches long, cutting these close up to a joint, and making each one fairly firm in the soil, which should be an equal mixture of loam and leaf-soil, with sand added, and a dash on the surface of each pot, which will work down with the dibber for the base of each cutting to rest

on. Water in the cuttings, and allow them to dry as much as possible before putting into the cases or frames, which need to be kept close, or nearly so, and lightly shaded from strong sunshine. In this position they will take rather longer in forming roots, but they keep clean and sturdy from the start. Any damping foliage must be promptly removed, and a strict look-out kept for slugs, which quickly devour the succulent growths. Here very little water will be necessary, but on a very bright morning, should the foliage be dry and inclined to droop, a very light dewing from the syringe may be given. Some varieties root more quickly than others. These should be removed to other frames, where a little ventilation can be afforded.]

NOTES AND REPLIES.

Chrysanthemum Kathleen Thompson.—Of all the sports of Chrysanthemum Caprice du Printemps, I think Kathleen Thompson is the best, its dark red blossoms being very effective either on the plant or for cutting. If disbudded, the individual flowers are of quite a good size. The plant is of moderate growth, scarcely reaching in pots a height of 3 feet, while its habit is all that can be desired. Further south, I understand the variety blooms in the open. Here, however, it must be taken indoors on the approach of frost. At the present time (November 7th) Kathleen Thompson is at its best.—W. McG., *Balmac*.

Chrysanthemum Sœur Melanie.—I was glad to read "Kirk's" appreciative note anent Chrysanthemum Sœur Melanie. My experience of this variety dates back twenty-five years ago, when I grew a number in quite small pots and edged a group of plants at an exhibition. It was then comparatively little known, and though one could not claim for it bigness in bloom, it had other good points—viz., free-flowering, dwarf habit, with foliage well to the pot, the blooms which gradually developed to pure white, generally being produced in clusters. It speaks much for it in these days, when so many sorts have joined the majority after a brief existence, to find that this pretty little variety has survived. It is one of those old sorts, like Source d'Or, that "time does not wither, nor custom stale." Sœur Melanie is a capital sort for growing in small pots from cuttings struck in May.—LEAHURST.

OUTDOOR PLANTS.

NERINE BOWDENI.

I THOUGHT this the most beautiful of hardy plants exhibited before the Royal Horticultural Society on October 24th last, when a fine group of it was brought from Guernsey by Mr. Frank Lilley. Welcome at any time, it is doubly so in October, when choice-flowering plants are becoming fewer in the garden. It is welcome, too, by reason of hardiness, and in this connection it has within it the possibilities of creating a new feature where the chief of the gardening done is in the open air. The warmth of its rosy-red flowers, produced in fine, spreading umbels, produces a quite unique effect. In well-grown examples an umbel may contain a dozen or more flowers, not of transient beauty, but giving a succession lasting two or three weeks. Radiating from a common centre at a slightly inclining angle on 2-inch-long pedicels, the flowers are bereft of the density and, to some extent, the formality of the majority, though modern hybrid Nerines are tending in a like direction.

A native of Cape Colony and first discovered in the mountainous district near King William's Town, it owes not a little of its hardiness, doubtless, to that fact, and is proving as hardy as the Belladonna Lily and some other Cape bulbs. To ensure its safety, however, it should be planted 5 inches or 6 inches deep, selecting as for the other plant named a warm,

sheltered spot like the foot of a south wall or that fronting a greenhouse. It was first exhibited and certificated in 1904 as *N. excellens major tardiflora*, the name being subsequently changed to *N. Bowdeni* on the plant being accorded specific rank. Eighteen or so inches high, its leaves are usually retained till the new flower-scape appears, when they perish. A warm and sunny position in loam, freely incorporated with old mortar and sand, and the deep planting already noted, are the conditions calculated to ensure its success.

E. H. JENKINS.

—Planted on a sunny south border in well-drained soil, this Nerine is proving a valuable autumn flower. Under conditions favourable to the Belladonna Lily, *N. Bowdeni* thrives at the foot of a south wall, and during October is very showy. When first introduced from South Africa about 1900, and distributed by Mrs. Cornish Bowden, of Oaklawn, Newton Abbott, it was thought to be a hybrid or variety. The bulbs first flowered in Ireland in the late Mr. W. E. Gumbleton's garden. One of, if not, the largest-flowered of all the Nerines, the rose-pink blooms are borne on robust scapes up to 18 inches high. It is a very distinct species. It seeds freely, and by this means and offsets it can be readily propagated.—*Irish Gardening*.

LILIUM REGALE.

THIS is, without doubt, the most valuable addition to the genus of modern times. It is also an acquisition from every point of view. Full of promise from the first, it has not only proved quite hardy in various parts of these islands and in America—in the latter Mr. E. H. Wilson reported in 1913 that "with the thermometer registering 42 degs. Fahrenheit of frost, and the ground frozen for 10 feet down, the bulbs came through unscathed"—but for amenability to cultivation and free-flowering it has no equal in the trumpet class to which it belongs. To these attributes must be added a prodigality of seeding which at once provides the cultivator with the means of gardening with it on a lavish scale, and, apparently, so far as present experiences go, without the misgiving that seed-production in its case means the loss of the bulbs. It has all those desirable qualities which go to make a good garden Lily, not being surpassed in this respect by the much better known *L. Henryi*.

First discovered by Mr. E. H. Wilson in August, 1903, when travelling in Western Szechuan for the Messrs. Veitch, it was originally named *L. myriophyllum* at Kew. Later it was discovered to be distinct from that species, and the above name adopted. Originally only some 300 bulbs were introduced, but in October, 1910, Mr. Wilson was responsible for the substantial importation of 6,000 bulbs, which arrived in America in the April ensuing, and, being planted, flowered well and ripened a good crop of seeds. It has been repeatedly shown in this country, and gained an Award of Merit in 1912, though, probably, no Lily has more richly merited "First-class" honours. Be that as it may, Lily specialists and all who have tried it recognise it as a first-class plant, and the demand for it is considerable notwithstanding the price is high.

CULTURE.—From the cultural point of view, while succeeding in sun and shade, it appears to revel and to attain its maximum—4 feet or so—in a good depth of cool loam, with which a free addition of well-decayed leaf-mould, a sixth of peat, and an equal amount of thoroughly-decayed manure and some sand have been incorporated. A stem-rooting kind, it is important that it be planted 6 inches deep at

least, in order that a maximum of such roots be formed and, in turn, afford support to the plant. For the same reason, too, an annual mulch of fairly rich soil or a renewal of the surface portion would prove beneficial. As promoting longevity at flowering time a partially-shaded position is best. The linear, lance-shaped leaves are each 4 inches to 6 inches long, frequently sickle-shaped, and densely crowd the stem to the base. Moreover, they are retained right into November—provided severe frosts are absent—and the cultivator has no better sign than this that all is well with his plants. Two to four of the great horizontally-disposed, trumpet-shaped flowers crown the growth. Flushed with a reddish colour externally, they are white and yellow within. The bulb, to those seeing it for the first time, usually disappoints, and it is quite possible to get a dozen into an ordinary cigar-box. Unlike any other trumpet Lily known to me, the bulbs are conical or ovoid in outline, the scales acutely pointed, and coloured a

spicuous by the presence at the base of the inside of the flower of a black, three-armed cross edged with gold. It is a beautiful late-flowering Tulip, which may be planted up to November, and in light soil needs hardly any attention, except lifting when the bulbs become crowded.—S. A.

Reseda glauca.—This perennial Mignonette is not often seen, but is a capital rock-garden plant. It has tiny leaves of a pretty, glaucous hue, reminding one somewhat of an *Ethionema*, and slender spikes of cream-coloured flowers, which are produced in great profusion. It likes a fairly rich soil with plenty of lime in it, and appears to be quite hardy. It is easily raised from seed.—N. L.

Verbascum Caledonia.—This is a true perennial, and of very good habit, having stout spikes of large bronzy-yellow flowers, which do not grow too tall. It can be increased readily by careful division of the root, and a good stock can be raised in this way. A good group looks very handsome when associated with other tall-growing plants, and it is not at all fastidious as to soil.—N. L.

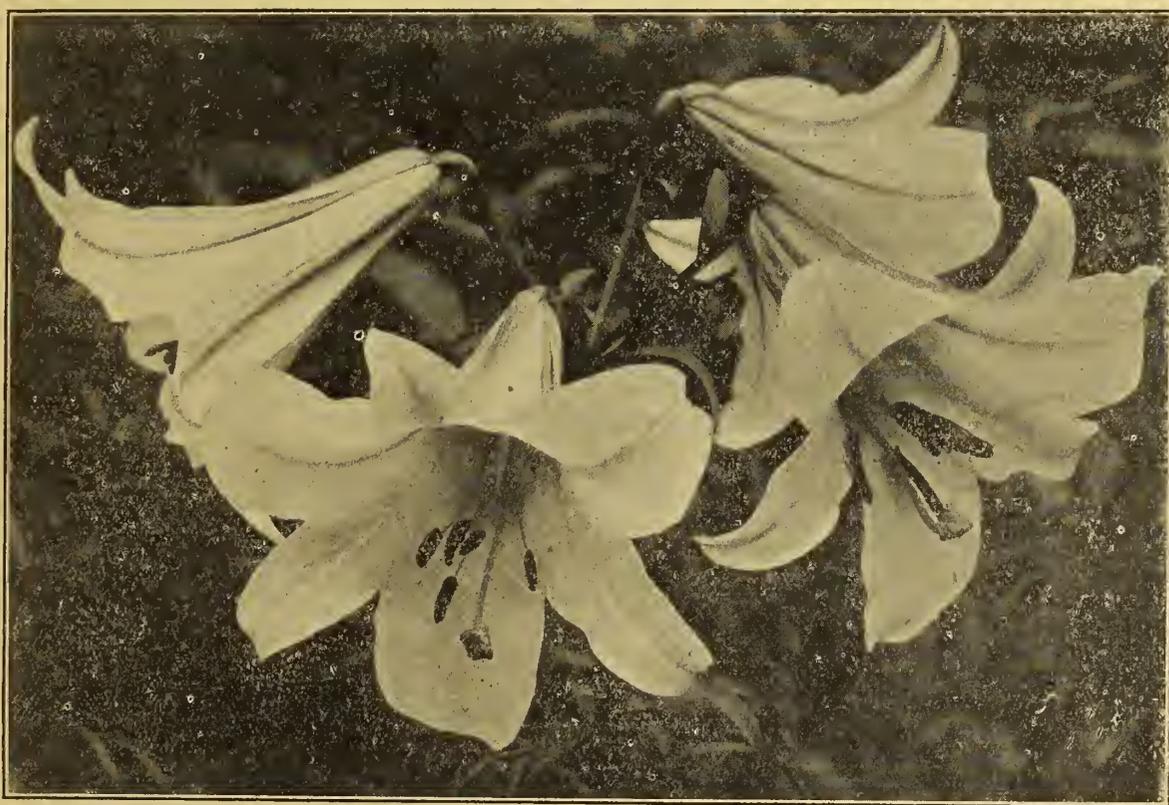

Saponaria Boissieri.—I have grown this on rock work for a few years, and find that it does

THE WEEK'S WORK.

OPEN-AIR GARDENING.

IN BLOOM NOVEMBER 15TH.—*Abelia rupestris*, *Ceanothus* (in variety), *Hardy Fuchsias*, *Veronicas* (in variety), *Solanum jasminoides*, *Andromeda polifolia*, *Correa magnifica*, *Jasminum nudiflorum*, *Laurustinus*, *Clematis* (in variety), *Roses*, *Myrtle*, *Choisya ternata*, *Hydrangea paniculata grandiflora*, *Phygellius capensis*, *Pentstemons*, *Antirrhinums*, *Michaelmas Daisies*, *Erigeron mucronatum*, *Potentillas*, *Fumitory*, *Mexican Poppy*, *Androsace lanuginosa*, *Parochetus communis*, *Sternbergia lutea*, *Hardy Cyclamens*, *Crocus speciosus*, *Dwarf Campanulas*, *Lobelia cardinalis*, *Primula japonica* (this year's seedlings), *Polyanthus*, *Nepeta Mussini*, *Ericas*, *Menziesias*, *Violets*, *Pampas Grasses*.

THE WEEK'S WORK.—The principal work during the past week has been the lifting and re-planting of trees and shrubs, the weather having been very favourable and the soil in perfect condition for the work. Not only is it a gain to have this work completed before the busy season, but the plants benefit greatly.

Lilium regale.

dark reddish-purple, much deeper, indeed, than those of *L. Henryi*.

So far as my experience goes, the plant is immune from disease. Retaining its leaf-growth till frost, and not ripening seeds before late October or November, planting should be done during the latter month where possible. Hence, collectively, we have here a species which, while ranking high with the best of its fellows, bids fair to surpass them all in permanent garden merit and value, which, after all, is the true test of any plant's worth.

E. H. JENKINS.

NOTES AND REPLIES.

Sedum primuloides.—"A shy bloomer!" seems to be the general verdict of those who have tried this, and it would be rather useful to have some details as to how those who grow it flower it. It is quite a pleasing plant, and is evidently quite hardy.—S. A.

Tulipa Eichleri.—Each flower, frequently 9 inches across, is of a most glowing deep scarlet, whose brilliance is made more con-

not differ very greatly from some plants of *S. ocymoides*. Any differences which exist are pointed out by Mr. Jenkins in the note which accompanies the illustration on page 503. It seems, in addition, to be rather less subject to being destroyed by an unusually wet winter—the cause of occasional disaster to old plants of *S. ocymoides*.—S. ARNOTT.

Labels in the hardy flower border.—At no time of the year is it so important to label plants as in the winter. Especially is this so in a garden where hardy-flowering plants are grown. It is so easy to unwittingly run the spade through a clump of Lilies when there is no foliage to indicate its whereabouts. Labels save much inconvenience and are often the means of preserving plants that would otherwise be possibly lost.—TOWNSMAN.

Convolvulus lineatus.—This is a beautiful Convolvulus of non-climbing habit, and is, in fact, one of the dwarfest of the genus. It is only about 6 inches high, with small silvery leaves, and bears pale red-purple flowers about the month of June. So far, however, it has proved a shy bloomer with me. The orthodox treatment—a warm position in dry and sandy soil—is not always effectual.—S. ARNOTT.

The ground being still warm, the roots will take possession of the soil at once, and, therefore, be much better able to withstand the drying winds which tax newly-planted shrubs so heavily during the spring. Successful transplanting depends to a great extent upon the care exercised in lifting. Secure as large and solid a ball of soil as possible by digging a wide trench round the specimen at a distance according to its nature and size. When re-planting, dig holes sufficiently large with a good margin for spreading out the roots and for fresh loose soil around the latter. Trim the points of roots that were broken and bruised in lifting, and lay them out carefully, covering with fresh soil, and making firm as the work proceeds. Give a soaking of water to settle the soil about the roots. Stake securely, and mulch with any loose protective material available. Charming effects can be obtained by planting suitable climbers on tree stems, and the present is the most suitable time for the work. In most cases the soil will need to be trenched and manured. Many varieties of *Roses* are very suitable for this purpose. The planting should be done at a distance of about 3 feet from the stem, and the roots placed with

their growing points from the tree, the object being, whilst training the growths of the plants up the trunk of the tree, to attract the roots away from the trunk by placing manure and suitable soil where the roots are wanted to extend. The chief points to observe in cultivating Roses in these positions are to keep them clean and well supplied with water in dry weather. In addition to Roses, many climbers may be planted in this way, including Clematis montana, C. flammula, Polygonum baldschuanicum, P. multiflorum, Rubus Bambusarum, Actinidia chinensis, Schizophragma hydrangeoides, Wistaria, Vitis (in variety), and Tropæolum speciosum. There are few plants to equal Michaelmas Daisies for late autumn flowering, but their beauty is often spoilt by allowing them to grow undisturbed for a number of years. They should be lifted and replanted every season if the best results are desired. The most suitable time to do this is immediately after they have finished flowering. Select only small pieces for replanting, as each shoot will make a good specimen. Although most commonly grown in the mixed border, they are seen to better advantage when planted in bold groups by themselves and on the margins of shrubberies or the banks of a lake or stream.

F. W. GALLOP.

Lilford Hall, Oundle, Northants.

SOUTHERN COUNTIES.

Fruit-room.—Particular attention should be paid to both Apples and Pears, and care taken that specked and decayed fruits are not allowed to remain on the shelves to endanger those which are sound. The temperature should be kept as cool as possible and light excluded. When a separate place is not provided for the storing of Pears, these should be put at the warmest end of the Apple-room.

Pruning.—Where there is much pruning to be done during the coming winter it would be a good plan to make an early start. Currants and Gooseberry bushes may first be dealt with, as the ground between them can then be manured and pointed over the first convenient opportunity. In pruning Red and White Currants, all side shoots and growths on spurs are cut back to two buds, and, unless necessary to extend the main branches, the leading shoots are cut back to four buds. Where necessary, shoots are left and shortened one-third to make good any gap occurring in any of the bushes through a branch dying or as the result of an accident. Young shoots or suckers springing from the base are remorselessly removed. With regard to Gooseberries, we prune these in accordance with the purpose for which the fruit is required. Those which supply berries for gathering in a green state have the wood left much thicker, the same being partly shortened instead of being spurred back. Very heavy crops generally result from this method of treatment; but if the produce had to remain on the bushes and ripen, the berries would, from want of a sufficient amount of sunlight and the fact of the crop being a heavy one, be inferior both in quality and flavour. Fruit for the dessert is, therefore, grown on bushes which are kept well thinned and the young wood spurred to two and three buds, the leaders being shortened or tipped just as circumstances demand. By growing them on this principle it is unnecessary when the break is not enclosed with wire netting to net in the whole of the bushes when the fruit commences to ripen.

Black Currants.—These require no spurring, but to have the heads of the bushes kept well thinned instead. The object to aim at is to have as much young wood as possible in them, to attain which the oldest should be cut out annually. This, with good cultivation in the shape of affording the roots a plentiful supply of manure, maintains the bushes in vigorous health and in a productive condition. When bushes are numerous and a partial loss of crop is of no serious moment, every other or one or two rows of bushes may be cut back hard now and again with the object of securing an abundance of young, vigorous growths. This course of treatment if followed up keeps the bushes free of old and decrepit wood. Where the Black Currant-mite is present to a limited extent the affected wood, as far as cir-

cumstances permit, should be carefully cut out and burnt, and the swollen buds picked off from all portions which cannot be spared. The mite-infested buds as picked off should be dropped into a bucket containing a sufficiency of paraffin oil to kill the mites they contain. If the attack is a bad one the only thing to do is to grub and burn the bushes forthwith and plant breaks in another part of the garden as far removed as possible from the old one.

Early-flowering Gladioli.—The planting of these should now be done, making groups of them in the borders and the forefronts of shrubberies where an effect alone is desired, and where required for cutting in quantity planting in a series of beds or in a border in the kitchen garden. Each group should consist of one variety only. Plant the corms 3 inches to 4 inches apart and about 4 inches deep, and place some sharp sand at the base of each. Lightly mulch the surface afterwards. When the soil is not suitable it always pays to remove it or otherwise to render it so by adding a goodly portion of fresh loam and leaf-mould.

Planting of Daffodils.—The value of these for embellishing those portions of lawns overshadowed by trees as well as under them when they are of a deciduous nature and do not form too dense a canopy is well known. Irregularly-formed groups planted in the Grass, in front of shrub borders, on banks, and in well chosen spots in the more outlying portions of the grounds are always effective, and once planted afford a display for years afterwards. The soil being in such a moist state, planting can, as a result, now be carried out in an expeditious manner. It should, however, as the season is so far advanced, be brought to a speedy conclusion.

Sweet Peas.—Where the plants are known by previous experience to pass through the winter satisfactorily, one or more rows should be sown at once with a view to obtain early flowers for cutting. A warm, sheltered, and well-drained position should be chosen, and every attention paid the plants when they appear above ground or they will speedily fall a prey to slugs. Sparrows also have to be reckoned with in the vicinity of towns.

Rose planting.—The planting of all kinds of Roses must be pushed on so that—weather conditions permitting—it can be brought to a conclusion by the end of the month. We have planted as late as the third week in December and with excellent results, but, when possible, prefer to finish at the before-mentioned period. In spite of so much wet weather, the soil is in good working condition, and there is not the slightest difficulty in getting plenty of it with which to cover and surround the roots before filling in the holes. If standards are to be planted the stakes for their support should be driven in first. Mutilation of roots is thus avoided. Trellis work for the support of Ramblers is now being erected. This is constructed of Larch poles in two sizes—those of a larger diameter for the uprights, and the less sized ones for the crosspieces and bracings. When the planting is completed a mulch of leaf-mould and spent Mushroom manure will be afforded.

Edible Peas.—The old-time practice of sowing a few rows of Peas in autumn now seldom obtains, but is, when climatic conditions are suitable, well worth doing, as if the plants survive the winter they yield an early supply. A warm border is the best position for them, and the variety should be one of the hardy or round-seeded types.

Broad Beans.—These are hardier than Peas, and can generally be depended on to come safely through the winter. A good sowing where pods are required as early as possible should be made forthwith on a well-drained, sheltered plot in the usual way, a good hardy variety for the purpose being the Dwarf Mazagan.

A. W.

MIDLAND COUNTIES.

Late Grapes have been cut and the stems placed in bottles filled with water. Two or three pieces of charcoal are placed in each bottle to keep the water sweet. The Grape-room is kept quite dry and a temperature of

45 degs. to 50 degs. maintained. When the bottles require refilling remove them from the room for the purpose. Under these conditions the Grapes will keep just as long as if they were left on the Vines. The removal of the bunches will permit of watering the roots, which are in need of a good soaking. Unless theinery is utilised for housing flowering plants the ventilators should be thrown open at all times. The welfare of the Vines must be considered, and air admitted freely whenever the weather permits. Partially prune the Vines to facilitate the ripening of the wood. The pruning and cleansing of mid-season Vines should be hastened as it is important to get as much of this work done as possible before the beginning of the New Year. The pruning of

Bush fruit will be proceeded with as soon as wall trees are finished. On Red and White Currants all side shoots should be cut back to within an inch or rather less of their origin, leaving about 6 inches of new growth on the main branches if extension is necessary. In the case of Black Currants the finest fruits are produced on wood of the previous year's growth. A few of the best-placed basal growths should be left to take the place of old and exhausted branches, which should be removed. Any young shoots of undue length should be cut back, and others not required entirely removed and the lateral growths on the main branches spurred back. Gooseberries may be pruned in two different ways—one by spurring back the shoots made during the preceding summer (which must be practised with cordon-trained Gooseberries), and the other (which I prefer for bushes) by retaining entire any shoots needed to form a well balanced bush, shortening those that exceed 1 foot in length and entirely removing any old branches and other shoots not required for furnishing the bush. In gardens where birds destroy the buds of Gooseberries the best remedy is to enclose them in a wire-netting cage, the sides of which should be removable to admit the birds at certain seasons. Failing protection, they should be syringed two or three times during the winter with some distasteful ingredient, choosing a fine day for the spraying.

Calanthe Veitchi and C. vestita are now ripening their foliage and pushing up their flower-spikes. Very little water will now suffice for the plants, but they must not be allowed to become dry until after they have finished flowering. Lillium speciosum, which has finished flowering, is kept rather on the dry side, and when all the foliage has fallen the stems will be cut down to the level of the pot before placing them in a cool and dry place, where they will remain until early in the spring, when it will be necessary to shake them from the old soil before repotting. Retarded bulbs potted in August are growing freely and are given weak liquid-manure.

Carrots.—Late crops that were raised from seed sown in July have had some partly-decayed leaves spread between the rows to afford protection during severe weather, as these roots will be allowed to remain in the ground until required for use. The reason for using the leaves in a partly-decayed condition is that they are not so likely to be blown about by the wind.

The herb border has been put in order. Useless and untidy growths have been cut away, weeds removed, and the soil neatly forked over. Roots of Tarragon and Mint have been lifted, planted in boxes, and placed in a warm-house.

Winter salads constitute an important part of the daily supply, and every attention is now given to the blanching and protecting of Endive. The plants have been removed from the open ground to cold-frames, and good batches are introduced to the Mushroom-house as required, thus keeping up a good and constant supply of first-class salad. Late sowings of

Turnips have made good progress, and a little soil has been drawn over the bulbs as a protection from frost. The largest that are fit for use have been lifted and stored in sand.

Jerusalem Artichokes have been lifted, the largest and best-shaped tubers sorted out for consumption and the smaller ones reserved for planting next season.

Digging and trenching are now the principal work. The sites for next season's crops have been fixed, and the ground is treated accordingly. On no account should heavy land be dug while very wet. When carrying out the work leave the surface as rough and lumpy as possible, thus exposing the soil to the weather.

F. W. GALLOP.

SCOTLAND.

Anemones.—In some districts the spring planting of Anemones may be necessary, but in these gardens it is found that good results are obtained if the corms are put out in late autumn. In the course of the week, therefore, a considerable planting was made. Departing from the old practice of putting Anemones into beds, it was decided to plant them at the foot of a fruit wall protected by a glass coping. It is hoped that they will give a good account of themselves in this position, and that the flowers will be available at a slightly earlier date than in the case of those planted in the open. A quantity of *A. fulgens* was put out, and the soil was lightened by a free use of lime rubble.

Irises.—At the same time, and under precisely similar conditions, a planting of Irises was made. We grow many of these in cold-frames merely for cutting; but the Algerian Iris (*I. stylosa*) does well under the glass coping of a Peach wall. The present planting included a good number of the Snake's-head Iris (*I. tuberosa*). This is not generally considered quite hardy; but our comparatively mild climate sometimes provides surprises for visitors, and I see no reason to doubt that *I. tuberosa* will do as well as *I. stylosa*. *I. histrio* and *I. histrioides*, like *I. reticulata*, appear to be difficult to obtain in quantity at the present time.

Ixias.—Encouraged by the success which has attended *Ixias* grown in the open, further plantings were made in the course of the week. These small bulbs may be planted quite thickly, and, so far as present experience of their requirements goes, they appear to relish, like Anemones, a mixture of lime in the soil. Their value for cutting where batches of a good size of one particular subject may be from week to week required is great. *Ixias*, it may be said, are very satisfactory as pot plants, but they do not seem to care for much forcing.

Stove.—The time is at hand when a slight reduction in the temperature may be safely practised. In October it is quite a simple matter to run the thermometer up to 65 degs. to 70 degs. with a mild expenditure of fuel. Now the nights get colder, and if a minimum of 65 degs. is aimed at it will be found that firing must be correspondingly brisk. Most practical men will not strive after a steady and unchangeable heat in the stove. It is much better to vary it according to the outside thermometer. At the present time the maximum at ten p.m. in the ordinary stove may very well be about 65 degs., and if at daylight the thermometer indicates 62 degs. no fault can be found. Less syringing is now needed—once a day being sufficient. I prefer to do this syringing in the early morning, but many like to do it about 3.30 p.m. It is merely a matter of opinion.

Chrysanthemums.—Every endeavour should be made during the present dull and rainy weather to keep down damp. Near the sea we suffer in an especial way from the humid atmosphere, and Chrysanthemum blooms are very readily affected by this. Ventilation is given amply both by day and by night, and a comfortable heat is allowed in the pipes. With full ventilation at 10 p.m.—full, that is, by comparison—a temperature of 55 degs. seems to be about the correct thing. Blooms are expanding well, and the Chrysanthemum season seems likely to be a prolonged one. I do not know how it may be in other places, here cuttings are developing much too rapidly. These if suppressed only result in weaker growths, and it is yet too early to put in cuttings with any prospect of success. It is difficult to know what to do for the best in such cases; but, following the advice of a gardener under whom I worked at one time, the cut-

tings are being put in. "The best time," he said, "at which to put in Chrysanthemum cuttings is—when you can get them."

Vermin.—At this time of the year in country districts there is generally an outbreak of vermin—rats, voles, and other pests—which draw in to the more sheltered regions of the garden on the approach of winter. During the week signs of such an invasion were noticed, and steps were taken to deal with it. Traps and poison were used, and after a few days quite a satisfactory clearance has been effected.

Digging is being persevered with on all suitable occasions. Broken weather has to some extent interfered with this work, but yet appreciable progress has been made. A Strawberry break which it was decided to dispense with has been well trenched, and a crop of Potatoes will be taken from it next year. A quarter occupied by Rhubarb had got rather untidy, and it was cleaned down and, for appearance sake, was lightly pointed over.

Hardy flower borders.—There has not yet been any frost, and there remains a fairly good display of Asters, Dahlias, Chrysanthemums, and the ordinary run of border plants. In these gardens these things are generally cut over about mid-October, so that the present season seems likely to set up something like a record for the duration of hardy flowers.

Among the vegetables.—A little time was devoted to removing decayed leaves from Brussels Sprouts during the week. The earlier lot of these useful vegetables has turned out well; but, as in the case of Cauliflowers, those put out at midseason have not been a success. At the same time, they may probably turn in at a very useful time. Growth is yet maintained among Leeks, these and Kale having been suited by the cool and moist summer. In the course of the week it was found possible to earth up the late Celery—a task which had been delayed by the continued wet weather. Jerusalem Artichokes, which have been rather severely dealt with by high gales, will shortly be cut over. These are hardier than is generally supposed, and may be left out all winter if the cut stems are laid crosswise over the bed. A look round was given to recently planted Cabbages, and any blanks or unsatisfactory plants were made good. Cauliflowers are now turning in fairly well, and if frost holds off this crop will not, after all, prove to be such a failure as was at one time anticipated.

W. MCGUFFOG.

Balmæ Gardens, Kirkcudbright.

NATIONAL CHRYSANTHEMUM SOCIETY.

NOVEMBER 9TH AND 10TH, 1916.

THE annual exhibition of this Society took place on the dates named in the Royal Horticultural Hall, Westminster, when flowers of the highest quality were seen. Many larger exhibitions have been held though few indeed have contained flowers demonstrating higher cultural excellence. This was so, indeed, in the large Japanese classes, where Mr. Stevenson, the gardener at Woburn Place, Addlestone, took the leading prizes for thirty-six, twenty-four, and twelve Japanese respectively—with blooms of uniform excellence throughout; and again in the large class for twenty-four incurved varieties, where Mr. A. B. Hudd (gardener to Mrs. Chalmers, Bickley) scored so well with perfectly-finished flowers. This class, indeed—a big test of cultural skill and judgment—attracted gardeners freely and was among the most admired in the show. We were pleased, too, to see those old types of incurved Mrs. G. Rundle and Mrs. G. Glenny figuring prominently in one of the exhibits, and should not be surprised to see a revival of them at any time. Exhibition blooms in vases are ever a big attraction and add greatly to the good effect by their handsome long-stemmed flowers. To those who prefer smaller or more elegant blooms the

singles, of which there was a great wealth, would appeal strongly, while the Anemone-flowered sorts, in greater excellence than of yore, are obviously attracting an increasing number by reason of their distinctive characteristics. Pot plants, whether decorative or grown on the exhibition plan, find little or no room in the exhibition hall to-day, and, indeed, these phases of culture are not catered for in the schedule. The most imposing exhibit in the show was a non-competitive one from Mr. Phillip Ladds, and constituted the feature of a good all-round display. Such exhibits tend to show the enterprise and enthusiasm which still prevail among horticulturists, and in all probability no finer group has ever been seen. Generally, competition was keen and but few classes were unrepresented. Several novelties received first-class certificates. Quite a crowd thronged the hall on the opening day.

The one confusing thing about the exhibition was due to the arranging of the exhibits, neither order nor sequence finding place. Classes 5 and 17, for Japanese blooms on boards and a display of singles in vases respectively, joined without rhyme or reason, and for a Society in its sixtieth year we expect perfection in such matters. It was but one of many like instances, and caused much inconvenience. Much time, too, was lost in an attempt to find the new varieties, and officials seemed powerless to assist. Following are some particulars of the show:—

In each of the leading classes for thirty-six—twenty-four and twelve Japanese blooms, distinct—Mr. T. Stevenson (gardener to Mr. E. G. Mocatta, Woburn Place, Addlestone) took the premier award with blooms of the highest quality throughout. His thirty-six were magnificent, and we select Mrs. Algernon Davis, Edith Cavell, William Turner (grand white), A. E. Roope (orange-yellow), Bob Pulling (rich yellow), and Miss E. A. Tickle (deep pink) as six of the indispensables in the lot. We have, however, rarely seen finer quality or a more uniform standard. This exhibitor also scored easily against seven competitors in the class for one vase of three Japanese blooms (white), employing that grand incurved variety William Turner, probably the best white in the exhibition. For three Japanese (yellow) Mr. H. Woolman, Shirley, near Birmingham, was in the place of honour with his new Seedling Shirley Golden. It is handsome and rich in colour. For twelve vases of cut Chrysanthemums (Challenge Trophy Class), three each of Japanese, Incurved, Single, and Anemones or Pompons, each vase to contain five blooms, the trophy was won by the Finchley Chrysanthemum Society, some half-dozen growers contributing the blooms. No other Society competed. Frank Tristan (bronze), Decartes (crimson, Anemone-flowered, and very distinct), and Mrs. Luxford (crimson Japanese) were three of the more weighty vases in a good all-round lot. The class for twenty-four incurved blooms, as already hinted, was a great attraction, and only rarely are such finely-finished examples seen. Of more exacting requirements, culturally, than the Japanese, their uniform quality merited the highest praise. The exhibitor who gained first prize was Mr. A. B. Hudd (gardener to Mrs. Chalmers, Farrants, Bickley, Kent). White Empress, Godfrey's Eclipse (golden), Buttercup, Hanwell Glory (bronze), and J. Wynne (pink) were a few in a nearly faultless lot. This exhibitor also carried off the leading prize in the class for twelve. For a collection of disbudded blooms in vases Messrs. Cragg, Harrison, and Cragg, Heston, were unopposed, their blooms being

very fine; the exhibit received first prize. E. Cox (incurved white), Pioncer (golden incurved), Max (very distinct red and gold single), Crimson King (a decorative sort), and T. Page (pink) were among the best. Messrs. Cragg and Harrison alone exhibited a collection of partially disbudbed or undisbudbed blooms, six vases of Anemone blooms securing the first prize in each. In the last-named, Aphrodite (deep lilac-pink) and Cordelia (red and fawn, with gold-tipped central boss) were the varieties shown.

Mr. A. R. Robertson (gardener to Mr. F. J. Yarrow, St. John's Wood Road) took the leading prize for a display of single-flowered varieties, Mr. A. B. Hudd (gardener to Mrs. Chalmers, Bickley, Kent) taking first for large-flowered singles, which have probably never been better shown. His set comprised Kathleen Wells (crimson), Isabel Felton (yellow), Stewart Smith (first-class certificate, a grand white), Caledonia (light amaranth), Bertha Fairs (terra-cotta), and Alberta (of reddish tone).

Mr. D. B. Crane, Archway Road, Highgate, was unopposed in the table class, and took first prize for an artistic arrangement of yellow and red single Chrysanthemums associated with coloured leaves. Mr. Crane also scored in the single vase class, Mr. Stevenson being second. The last-named exhibitor was in the place of honour for three vases of Chrysanthemums, in one of which the original types of incurved (Rundle and Glenn) were shown. Mr. Crane had the finest basket of Chrysanthemums and took first prize.

NON-COMPETITIVE EXHIBITS.

By far the best of these was that from Mr. Phillip Ladds, fine flower quality and artistic effect being combined. In a central position at the western end of the hall it constituted a most imposing display. Fifty big blooms of the white Mrs. Gilbert Drabble were in the centre, with vases and stands of such as Sandown Radiance (brilliant crimson single), Edith Dimond (single golden-bronze, first-class certificate), Edith Cavell (bronze), Phyllis Cooper (golden single), and many others. Rosamund, an exhibition variety of old rose colour, was one of the most distinct. A Gold medal was awarded. Messrs. Cragg, Harrison, and Cragg showed good Anemone-flowered sorts in their lot, Snow Queen, Aphrodite (pink), Ceres (rich yellow), Cordelia (fawn and red, first-class certificate), and Mabel Weston (white) being some of the best. Mr. Norman Davis had Mrs. Algernon Davis (clear pink) and Mona Davis (pink), both exhibition varieties, among many; also Sandown Radiance, one of the most brilliant. (Gold medal). Messrs. W. Wells, Limited, Messrs. H. J. Jones, Limited, and Messrs. Godfrey and Sons were also given gold medals for collections already noted in a previous report. A dozen or so new varieties, described on page 596, were awarded the first-class certificate.

CORRESPONDENCE.

PLANTS AND FLOWERS.

Blue Hydrangeas (G. H.).—These are very popular, but there is always a large amount of uncertainty about obtaining the flowers of the right colour, even when, as far as our knowledge goes, we adopt what is considered the best means to secure the object in view. The following compost for plants in pots has been recommended:—One half should be turfy loam, broken up with the hands, but not sifted, the other half a mixture of peat, crushed charcoal, and about 2 lb. to the bushel of iron filings. It is generally supposed that the blue colour is due to soil which contains iron.

Azaleas in bad condition (Rex).—Your Azaleas have been badly attacked by thrips and red-spider. Syringe or spray them with paraffin emulsion, Quassia extract, or Tobacco-water. If you could move them into a small house and fumigate them well, this would clear off the pests. A cheap insecticide for destroying these pests is as follows: Tie up a peck of soot in a canvas bag, and place it in a hogshead of soft water. Stir the bag of soot about daily for a week, and then when clear syringe the plants, diluting if need be. Try it on one or two plants first. This is an excellent syringing mixture, not only freeing the plants from insects, but giving health and vigour to them.

Salvia splendens (A. T.).—The old plants, which during the winter should be given sufficient water to keep them from being dried up too much, should next spring be given a temperature of 50 degs. to 60 degs., when, if kept moderately moist, they will soon push out new shoots, which, when large enough, must be taken as cuttings. The cuttings should be put into pots of sandy soil, and in a warm propagating case will soon root. After this they must be potted singly, and as soon as the roots take possession of the new soil the tops should be pinched out in order to encourage a bushy habit of growth. If shifted later on into 5-inch pots, and kept growing in the greenhouse, they should form good-sized plants, which will flower during the autumn and early winter months.

FRUIT.

Cracked Pears (G. Whiting).—The spotted and cracked condition of the Pear you send is due to the malady termed black-spot, or Pear-scab (*Fusicladium pirinum*). The remedy is to spray the tree with Bordeaux mixture at full or "winter" strength when the buds are about to burst in the spring, and at half or "summer" strength after the fruit is set and swelling off, and once or twice afterwards, allowing fourteen days to elapse between each application. As this fungoid disease is often to be found on the young wood, it is essential that the trees be thoroughly sprayed when resting in the winter. A combined fungicide and insecticide, such as Wohurn wash, is best suited for this purpose, and this, together with the Bordeaux mixture, can be obtained from any garden sundriesman. The cracking of Pears is sometimes brought about through the roots having descended into the subsoil, which in all likelihood has happened in your case. The remedy, then, is to lift and lay out the roots anew in a nearly level position and to place some new compost consisting largely of fibrous loam and some charred refuse round them to encourage the formation of fibrous roots.

SHORT REPLIES.

Halesby.—See reply to "R. A. T.," re "Sawdust as manure," and that to "Sweet Briar," re "Wood shavings," in our issue of November 18, page 587.—**G. Hill.**—If the wood in the trees is all like that sent, they will never do any good, and the best thing you can do is to grub them and put young, healthy trees in their place. On such a soil as you have it would be well to clear out the stations to a width of 3 feet and 2 feet deep for the fresh trees and substitute good loamy soil before planting.—**Gerald Martyn.**—The Rose you mention is said to be of vigorous growth, and should do in the position into which you have put it. We should, however, have chosen such a Rose as Mme. Berard.

CATTLE POISONING AT OCKHAM.

If any record could be kept of the deadly effects upon horses and cattle through eating even small portions of Yew it would show an amazing destruction of useful creatures. Recently one such sad accident which has taken place in a beautiful place in Surrey should open all eyes to the danger of planting Yews as freely as is now done without any artistic aim.

On Ockham Park Estate, Surrey, six of a number of heifers which had been turned out to graze on land in the occupation of Messrs. Gimmell, of Bridgefoot Farm, were found to be dead, and a number of others were in a serious condition as a result of their having eaten portions of the foliage of the Saffron Yew-trees, of which there are a number in the enclosures around Ockham Park House. The animals, the property of Mr. Ewings, of Bramley, had been taken in for grazing on that part of the Ockham Estate which is included in the Bridgefoot Farm. A gate leading to one of the enclosures was, it is said, inadvertently left unfastened, and the cattle thereby gained access to the Yews. A seventh heifer afterwards died.

The animals seem to die quickly, and apparently without much suffering, as if the heart were paralysed. Just as the French speak of the harm to cookery done by cooks, so we may say of our pretended landscape architects who scatter this murderous tree about the country place. It is the common resort of all who copy plans to plank down dark lines of Yews, although there are other evergreens much better for the purpose. The idea is common that cattle will not go into the garden or where these trees are placed, but they do get access to garden or pleasure ground, and often with a fatal result.

The right place for our native Yew, which is so deadly to animals, is in the wood or in some way cut off from any possible access to it by animals. Where the trees are old their stems should always be cleared to a height of at least 15 feet of all the lower branches, which are often worn out and useless to the tree, and merely hide the handsome boles. Often I see old Yews clad to the ground, their noble stems and colour concealed from the eye. Properly treated, the Yew is a noble ornament, and may, with care, be harmless.

From the point of view of beauty the tree may give, it should be enjoyed without risk of loss. The old and stately tree, with the finely-coloured stems, may be considered safe, and also old trees in woods which, from their woodland associates, often lose their lower boughs. If not, trees should be boughed and the

cuttings burned on the spot, also branches broken off in storms. Stock so often breaks through fences that where Yews abound there is danger of great loss, as occurred at Fillingham Castle. It is well, therefore, to have woods looked through and all boughs taken off and burnt. This practice does no harm to the old trees. In my own case I have young trees in woodland pruned up out of harm's way, and this practise helps the tree to get out of the spreading habit.

A fact that puzzles some and leads to vain discussions is that Yew-trees may exist for years in a place and do no harm, and then a sudden fatality may come. Growth is so rapid in some soils that boughs may come within reach of the animals, and it is likely an animal may be more liable to injury at certain seasons or states of the stomach. W.

NOTES OF THE WEEK.

A mare's nest!—We see in a paper that there is a new gain to our flora! Some forms of the South African plant one can hardly stop the growth of even in poor soil. No doubt it got thrown out in soil.

An addition to the flora of the British Islands has been found in the Montbretia—a near relative of the Iris and a native of South Africa—which recently was seen in bloom between the stones of the beach at Cobb, near Lyme Regis, in Dorsetshire.

Cotoneaster microphylla.—The illustration (p. 557) shows the value of this plant for covering objectionable sites. As a wall plant it shows to good effect when covered with its handsome berries through the autumn and winter. On a cottage close here the south front, 12 feet high, is covered, and has been so for many years, the plants flowering and fruiting freely. A pity it is not seen more often, seeing how easily it is increased from cuttings, or, better still, layers.—S. P., *Hants*.

A charming rock spray (*Cotoneaster Hookeri*).—Thinking I had some just idea of these shrubs, dwarf or tall, I saw one at Sheffield Park which surprised me by its brightness and distinction, the berries as gay as those of any, but the shrub standing erect, yet throwing its arms as gracefully as *C. horizontalis*. We owe the increase of this to Mr. T. Smith, of Newry, who saw its merits early and has a fine stock of it, so I have planted several groups of it in various aspects. What we owe to these precious shrubs is not always seen in gardens, there are so many, and they ask for some knowledge of their ways and forms to get their true value.—W.

Verbena venosa poisonous.—I was sorry to see this plant classed as poisonous by "K. M.," page 575. What does "K. M." mean by saying he trained the plant? A few sticks, twiggy or straight, according to fancy, is all this plant requires, making much handling of it unnecessary, unless one takes up the plants and pots them (as I have done) to ensure a safe wintering. Even so, I have not experienced any ill-effects, nor have I heard of any other gardener having done so. It will be a great service if other growers of this *Verbena* will give their experience.—C. TURNER.

Cotoneaster rugosa Henryi.—This pretty Chinese species is, by reason of its habit of growth, admirably suited to growing against a wall. Its peculiar habit of growth is such that it may be trained horizontally in fan-shaped outline against a wall with good effect. The wrinkled lance-shaped leaves, each 3 inches to 5 inches long, are distinct from those of most members of its tribe, while the clusters of brownish-crimson berries at their base in August and September are a considerable attraction. No member of the genus is more distinct, and few are so ornamental.—S. S.

Carnation Bishton Wonder.—To attempt to describe the colour (or colours) of this remarkable variety is a little risky, though it may safely be said of it that it is one of the most fragrant Carnations of the Perpetual-flowering class which has up to the present been introduced. The perfume is that of the old Clove in very pronounced measure, and the fact will ensure for it many admirers. It is of the fancy class, and that phase of it in particular which embraces the "heliotrope" and other nondescript shades, which would be even more out of place elsewhere. It is a large and handsome flower, and distinct in its way. Messrs. Allwood Brothers have shown it freely of late.—E. H. J.

Chrysanthemum Ceddie Mason in the open air.—It is not often this fine single *Chrysanthemum* blooms out-of-doors; but at present (November 18th) it is in good form in a border. This, of course, is attributable to the mild weather so far experienced, no frost having as yet been registered. I have been comparing the colour of blooms from the open with that of flowers from plants in the greenhouse, the comparison being decidedly in favour of the former. There is a greater richness in the blooms from the open, and they are quite two shades darker than those grown under glass—the latter being more of a reddish shade, while those from the open

almost approach maroon in colour. *Sylvia Slade*, too, has bloomed here out-of-doors during the present season.—W. McG., *Balmoe, Kirkcudbright*.

Hakea laurina.—Cut branches recently shown by Messrs. R. H. Felton and Sons of this South-west Australian shrub attracted much attention. At a short distance the exhibit was frequently mistaken for one of the several blue Gum-trees (*Eucalypti*) which the firm named shows from time to time. The foliage is thick, firm, intensely glaucous, Mistletoe-like in outline, though twice or thrice its size. The reddish stems are very effective in conjunction therewith, the ball of crimson and sulphur-yellow constituting the floral parts and appearing in the leaf-axils. Like the *Eucalypti*, it is well suited to decoration, lasting many weeks in presentable form.—S. V.

Cynoglossum amabile.—This is one of the most beautiful annuals of recent years. On seeing a bowl of it recently arranged with pink Roses I was charmed with its beauty. In some instances this plant had been used as a groundwork to yellow Roses. The bunches of good blue flowers are abundantly produced on stems 18 inches or so in length, and are useful for cutting. The plants continue to flower the whole season through. The seeds should be sown about the end of February and the seedlings pricked off into boxes. When hardened off they may be transferred to the open. The plant is so easily grown in this way that there should be no difficulty in securing plenty of plants.—E. M.

The wild Clematis (*C. Vitalba*).—The note by "W." (page 575) afforded me no little satisfaction, for I also have failed to appreciate *C. Vitalba* as warmly as Mr. Cornhill does. Mr. Cornhill is in error in regard to this *Clematis* being found only "on a chalk subsoil." It flourishes with us here where there is no lime or chalk. Indeed, there is an immense bush of it at this moment in a neighbour's garden. It looks like a very dirty sheep of gigantic stature, and one of these days the seed will be scattered over our borders, shrubberies, rock-gardens, and walks. This it does with unflinching regularity every year, so maintaining a succession of seedlings which spring up where they are least desired.—A. T. J., *N. Wales*.

Rose Tea Rambler.—I see in GARDENING ILLUSTRATED for last week (November 18th) your correspondent speaks of *Rose Tea Rambler* as being unsuitable for places where the winters are inclined to be severe. I have grown it here (at Ely), where the winters are intensely cold and damp, with the greatest success. I have two, both well over 10 feet high, and in June they are a mass of the loveliest pink Roses, growing in beautiful clusters, and the branches festooning themselves in the most graceful and luxuriant way, the foliage as well as the flowers being very beautiful. It blooms earlier than any other *Rose* of the kind, and for that reason, and for its wonderful beauty and extraordinarily strong and quick growth, seems to me a most valuable *Rose*, and I am quite sorry to see it depreciated.—AGNES RANDOLPH, *The Almonry, Ely, Cambridge*.

Flowers from N. Devon.—I picked these blossoms this morning (November 13th). The plants from which they were gathered have all wintered several years out of doors. We mat them in the coldest weather and cover their roots with leaf-mould and stable-manure rotted down together. Of course, I might lose them any year if we had unusually severe weather, but last winter was very trying, as we had a "wet frost" and the mats froze to

the creepers. I cannot understand why I do not succeed with *Streptosolen Jamesoni* out of doors when these things succeed all right.—ROSAMOND A. CHRISTIE, *Tapley Park, Instow, N. Devon*.

[With the above note was sent a gathering of flowers, among them being those of *Passiflora*, *Abutilon*, *Salvia Greggii*, *Buddleia asiatica*, *Cytisus racemosus*, *Cassia floribunda*, *Habrothaunus elegans*, *Plumbago capensis*, *P. c. alba*, *Correa*, and *Fuchsias* in many varieties.]

Prunus Miqueliana.—This species of *Prunus*, which was first introduced by Mr. T. Smith, of Newry, a few years ago, was at that time known as above, but since then the names of *P. microlepis*, *P. microlepis* Smith, and *P. subhirtella autumnalis* have been applied to it. The question of which is the correct name can be left for botanists to quibble over. It is remarkable among the *Cherry* family from the fact that the pretty semi-double flowers are borne during the late autumn months. They are each about an inch across and are freely produced on the leafless branches. A pleasant fragrance adds to their attractive features. When first expanded they are white, but become suffused with a little colour afterwards, especially towards the centre. Its origin is unknown, but it is generally supposed to be a cultivated form from Japanese gardens.—K. R. W.

The Blue Hound's-tongue (*Cynoglossum amabile*).—I take the English title conferred on this plant on page 551, but it is not very distinctive, for have not all the *Hound's-tongues* blue flowers? This one deserves all the praise bestowed on its beauty by "W.," but unpleasant experience prompts me to utter a word of caution in regard thereto. It ripens seed in greater profusion than others of the family, and the nuts are little burrs of extraordinary adhesive power. Under a lens it may be seen that they are so closely studded with little hooks that when they get into a dog's hair or a cat's fur it is impossible to relieve the animal of the intense irritation caused, except by cutting away part of its coat. I rejoiced when this plant took to sowing itself in open parts of the woods. The lovely sky-blue blossoms persist long after most flowers have disappeared, but it is not good to think of the suffering inflicted upon wild furry animals. Even the obnoxious rabbit is entitled to expiate his iniquity in a less excruciating manner.—HERBERT MAXWELL, *Monreith*.

Chrysanthemum Florrie King.—Although generally classed as a variety for flowering under glass, I find this one of the best kinds for growing in the open air. The habit of the plant is tall, but the stems are stiff and well branched, and, therefore, staking is an easy matter. The single flowers are large, of fine form, and of a delicate pink colour, and develop wonderfully when cut and placed in water. I do not think it is necessary to stop this variety, but the buds should be thinned. If a spray of good-sized flowers is desired the principal central bud of each shoot should be removed, as the side blooms are on longer stems. Very large flowers, each from 3 inches to 4 inches across, can be had by retaining the central bud and removing the surrounding ones. The growth and foliage of this variety are very satisfactory, even when the new shoots proceed from the old ones cut down the previous autumn. Root-suckers are not freely produced on my plants, but would probably be induced if the old stems were cut down to ground level. As grown by me, this variety flowers during the first three weeks of November.—G. L. J., *Croydon*.

FRUIT.

PRUNING AND NAILING FRUIT-TREES.

MANY gardeners commence to prune and nail the trees on south and east walls, leaving those on the north walls till last. This, in my opinion, is a mistake, for those trees on warm aspects that are nailed and pruned early commence to grow too soon, while those on the north are retarded. To show that this is so, you have only to hang a thermometer against them to determine this. The walls often get warm, and as the heat is absorbed they will retain it for some time, giving it off later in the day when the sun has declined. Here, then, is the cause of so much mischief from early nailing on these walls. We often experience bursts of bright sunshine in early spring after a cold, frosty night or a sharp frost follows a bright day; the sap, being active, gets frozen and causes a check. This, no doubt, is in a great measure the cause of *Apricots* growing against south walls doing so badly in the southern counties. If these were left unnailed till late in the season they would doubtless be considerably retarded in their growth. I commence on the *Morello Cherries*, and follow on with all the trees on north walls. Those on western aspects are done next, then those on the east, leaving the south walls till last. If *Morello Cherries* have been taken in hand during the late mild weather the work will have been done with more comfort and in much less time than when deferred till cold, frosty weather sets in. The walls, too, can be cleansed more effectually than when they are frozen. One of the great secrets in the successful cultivation of this fruit is to rid the trees and walls of any insect pests during the winter, and this can readily be done as soon as the leaves have fallen. It should be the practice to unnailed and liberate all growths every second year. If half be done each autumn the task will not be so great as when all are left to be done at once. When the trees are liberated the walls should be washed with strong soft-soap water to which a little sulphur has been added. New shreds, which should be cut as narrow as possible, should be used. The stout branches should be fastened to the wall by pieces of golden *Willows*, as these are much neater than shreds, and not so liable to cut into the wood as tarred twine. It is not well to overcrowd the shoots, as the trees would not be able to support all the fruit that is set. Where the trees are not liberated the walls should be thoroughly syringed with soft-soap water after nailing is completed. *Plums* on north walls should next receive attention, the wood being washed and made clean. All dead spurs should be removed and others cut back to two or three eyes. Where trees receive due attention during the summer, and the ground is light, there will not be over-much growth to remove, but where neglected and the soil is stiff, strong growths will have been made which are by no means the most useful. Having completed the *Plums*, attention should next be directed to *Pears*. Trees should be freed from scale and other pests, every shoot being examined to make sure that the shreds or ties are not defective, for when the fruit is approaching maturity it is very annoying to find that some of the branches are broken down by its weight. By the time such trees are nailed, the winter will be getting advanced, so that it will be safe to prune and nail *Cherries* on the various aspects. These may be followed by the *Apricots*, and finally *Peaches* may be taken in hand. The advantages of leaving these till the

last are manifold. Not amongst the least is the retarding of the blooming period by keeping them away from the warm walls, as previously noted.

Nailing forms an important part in the successful cultivation of fruit, in the south, at least, and those who make close observation of time and seasons will be able to note the difference between the growth of trees that are nailed early and those that are left loose till late in the season.

T.

NOTES AND REPLIES.

Strawberries in fruit outdoors.—On established Strawberry beds I find many of the plants are flowering and fruiting, some fruits being now ripe. It may have been possible to lift some of these plants and place them under glass, and thus save

berry, because of its shallow root-hold; more, of course, in some soils than in others. Whether the soil be light or heavy, shallow or deep, drought affects all Strawberries, more or less, and I am satisfied it is premature ripeness, set up by drought, that has promoted this autumn cropping.—W. S.

The Himalaya berry.—This new berry is an extraordinarily prolific Blackberry, and, unlike most of its cousins from the States, it has the real Blackberry flavour and continues to fruit over a long season. In growth it rivals, if not surpasses, the Loganberry, and plenty of room must be allowed. Large bunches of fruit will be produced on the current year's growth, and it also continues to fruit from the old wood.—*The Garden.*

Old Vines—pruning.—Some years ago, when taking charge of a fresh garden, I found some

TREES AND SHRUBS.

ESCALLONIA MONTEVIDENSIS.

This is the handsomest flowering shrub in the garden at the present time (November 2nd), and is worthy of more extensive cultivation. Unfortunately, it is somewhat tender, but it succeeds in the open here, planted in a sheltered, well-drained border, and has stood 16 degs. of frost without protection, beyond a mulching of leaves. The plant from which the sprays figured were cut is about 7 feet high and 4 feet through; it has been in flower for more than a month and promises to remain in bloom for several weeks longer. The white blossoms are borne very freely in large terminal panicles and are useful for cutting.

F. W. G.

Lilford Gardens, Northamptonshire.

PLANTS UNDER TREES.

From a list of plants suitable for covering ground under trees, which appeared in a recent issue, Periwinkles are unaccountably omitted. They thrive in rather dense shade and where the tree-roots are near the surface. We have the plain-leaved kinds in variety, and the silver variegated and golden variegated varieties. Some pieces of the latter were planted some years ago under a big Wellingtonia from which I was obliged to cut some of the lower branches, leaving a naked stem several feet high. The Periwinkle has now covered the ground with a dense carpet of foliage some yards square, and to those who do not object to variegated plants, has a nice appearance, especially from now onwards through the winter. This variety blooms, but not freely, but the green-leaved kinds are fairly free in this respect. I do not think that the Epimediums get quite the attention they deserve. In one way they are remarkable, for they thrive in the sun and luxuriate in the shade. I have seen a dry bank in the full sun covered with them, and after some two months' dry summer weather they looked fresh and bright. At the same time, they are quite at home under trees, and certainly keep their verdure better there during the winter than when exposed to icy winds. There are pretty well a dozen varieties in cultivation, and they all bloom with more or less freedom, *E. sulphureum* being, I think, the best, the pale yellow blossoms contrasting nicely with the bronzy-tinted foliage, which is characteristic of this family and which renders them valuable not only in the outdoor garden, but also for cutting where evergreens are needed for indoor decoration during the winter. Another thing that I have always thought is not thoroughly appreciated for this purpose is *Cyclamen neapolitanum*. One sees this generally as isolated specimens or several plants together in the rock garden, and frequently not in perfect health and vigour. The true way to use this *Cyclamen* is in the form of colonies, more or less large, and under deciduous trees where the bulbs are naturally fed by the leaves that annually fall on them, and where they enjoy a certain amount of protection from hot sun when the foliage is completing its growth. The leaf development under such conditions is very different from the pinched growth made in the open where there is no natural mulch. Two years ago I planted about fifty good bulbs at the foot of a Douglas Fir which has a clear bole of some 8 feet. The soil is eaten up with roots, but the *Cyclamens* are doing splendidly and have covered the ground with finely-developed foliage, and they bloom well. The needles from the Fir, which is some thirty years old, furnish just the

Flowering shoots of Escallonia montevidensis.

these unseasonable fruits, but my experience is that Strawberries do not find much favour at this time of year. These crowns that are now giving this premature crop may not respond again in the spring. I am not quite sure that this is true, for there have been years when the same thing has happened, and the pessimist has said that a short crop would follow, because of the autumnal bearing. This was by no means apparent when the flowering time came round in the following year. It may be that these precocious crowns do not give a spring flower-truss, but the subdivision of the Strawberry plant into so many separate crowns will relieve any anxiety as to the future prospects. This fruiting in autumn occurs on both young and older plants, and may have been set up by the short spell of drought in July. This is always acutely felt by the Straw-

old Vines that had been hard pruned for many years. The first time I pruned them I began to lay in young shoots from the bottom, and in three years I had new rods, which gave me larger bunches. Treated thus, these old Vines improved. When at Hampton Court, I noticed how much larger the foliage and bunches were where young wood had been induced to start from the base of the Vines.—DORSET.

Red Currants.—A beginning has now been made with pruning Red Currants. In the case of old bushes the operation merely consists in cutting out decaying or unfruitful branches and in shortening back the current year's growths. An eye must be kept to the due extension of the plants, and, above all, to keeping the centre of the bushes open. Do not permit prunings to lie about. If laid out in handfuls as the pruning goes on they are much more easily collected than when they are allowed to fall as they are cut. The above remarks are also applicable to White Currants.

nourishment they need. Primroses do remarkably well under deciduous trees, the protection from early frosts when in bloom and from hot sun later on is what they love.

J. CORNHILL.

NOTES AND REPLIES.

Arbutus Unedo and the birds.—In a recent issue of GARDENING ILLUSTRATED "W. O." refers to the unusual freedom of the fruiting of this tree in his London garden, and remarks, "What a lovely sight it will be when the Strawberry-like fruits are fully developed." The vagaries of birds are such that the pleasure of seeing the fruit is very often denied to the owner. The habits of birds vary from year to year, and in one garden I can recollect the Arbutus fruits remaining over a prolonged period, birds not preying on them, at any rate, as soon as coloured. In another locality birds seem to be in waiting, and, attracted by the bright scarlet colour, the berries disappear very quickly. It is discouraging to plant with the object of providing such a fine winter feature when there is a danger of the fruits being destroyed by the birds. Thrushes, and perhaps blackbirds, are the culprits; possibly the missle thrush is the greatest offender. In order to obtain the fullest advantage from such fruiting trees they need to be planted where they come under the eye, or it may happen, as in my case, that the birds will soon clear the fruit. Some three years since our trees were laden with fruit, but, being somewhat isolated, only occasional inspection was possible. By the time the fruits were fully coloured all were cleared. I can recall a group of this Arbutus growing on an elevated bank in a Somerset garden, the soil being poor and heavy. Here birds did not molest them. The growth, being somewhat thin and stunted, displayed the bright fruits to much advantage, and the trees were attractive for weeks. When planted in rich soil the growth is vigorous and the fruits are not borne so freely. I cannot understand why birds take the fruits with such avidity, for they, as far as I remember, are tasteless and insipid. It may be other food is short when birds raid Arbutus, while the colour and shape, suggesting the Strawberry, may deceive the birds.—WEST WILTS.

Cotoneaster congesta.—For the rock garden I consider *C. adpressa*, *C. congesta*, and *C. humifusa* far the best of this genus as we know it to-day. Quite recently I have written in appreciative terms of the first and last named, and now direct attention to the above-named in order to complete a trio of rock garden indispensables. In the mind's eye there is a blunt pinnacle piece of rock 2 feet high, with rugged base from which the point rises, the whole $3\frac{1}{2}$ feet high. Doubtless it was the lateral spread of the base of the rock which suggested the planting of the Cotoneaster now in mind, and which today garnishes its summit and sides in quite a unique way. No word-picture can convey the good resulting from this association of rock and shrub, though a knowledge of the plant, in conjunction with the character of the rock against which it was placed, would reveal much to the intelligent planter. It is by the studied use of some of the best of these rock shrubs that the rock gardener of today has advantages. *Cotoneaster congesta* (syn. *C. microphylla glacialis* or *C. glacialis*) is a neat-habited, slow-growing evergreen alpine shrub, spangled in autumn with scarlet fruits. In its rock-clinging character it is charming.—E. H. JENKINS.

Escallonia macrantha.—This should be more extensively employed as a hedge plant, in the shrubbery or as a wall plant on any

aspect. To cover a north wall or fence it is especially valuable. In South Hants it luxuriates in all sites in which I have seen it planted. In North Wales, near the sea, especially about Colwyn Bay, it is the plant for small seaside gardens, growing freely and flowering abundantly. In Cornwall it grows even more freely. Cuttings taken in September strike freely in a cold-frame and quickly make bushy plants; indeed, in the open they root readily if inserted in gritty soil on a north border.—S. P.

The Lemon Grass perfume.—Once a year the hillsides of the Malabar coast of India are the scene of great commercial activity during the Lemon Grass harvest. Oil extracted from the Grass is employed in the manufacture of perfumes. The hillsides are burned over to destroy the old and useless Grass. Six months later the fresh crop is ready to be cut, and at once the countryside is dotted with furnaces and stills.

PLANTS AND FLOWERS.

FERNS.

THE ROYAL FERN (OSMUNDA REGALIS).

This is undoubtedly the most stately of the numerous British species belonging to the genus, as it attains proportions unknown in any other native kind, the usual length of its fertile fronds being about 3 feet, but its barren ones, which are much more numerous, attain an average of about 6 feet, and frequently double that height when found growing in a particularly suitable spot. The Royal Fern is distinguishable at first sight from all other native kinds through its peculiarly massive fronds, furnished with broad, somewhat heart-shaped, and almost stalkless pinnae of a light glaucous green colour. It is equally distinct from all other native Ferns by the peculiar conformation of its fertile fronds, which have caused it to be sometimes called, though erroneously, the Flowering Fern. In these fertile fronds the upper pinnae are divided and changed, as it were, into dense clusters or spikes of terminal capsules, which form a compound, loose cluster or panicle, while the basal parts of the said fronds are in all respects similar to those of the barren ones. Both are borne on smooth stems of a reddish hue when in a young state, but turning with age to a pale green colour. It is not alone by its foliage that this most noble of all British Ferns can be recognised, for its peculiar mode of growth is unique. Its fronds rise from the crown of a root, which, unlike that of any other native Fern, is tuberous, of a woody nature, scaly, sometimes rising erect as much even as 2 feet above the ground, and forming then a miniature Tree-Fern of somewhat bulky appearance, while at other times its root-stock extends horizontally, or nearly so, for about the same length; but it is, in all cases, furnished with numerous strong, fibrous rootlets.

Though not by any means common in all parts of the United Kingdom, in places congenial to its growth the Royal Fern is found plentifully, and in such positions has grown into huge masses. The *Osmunda regalis* is of easy cultivation; for open-air culture it prefers a damp, shady situation, where it requires but little care, and when planted in spongy peat and allowed abundance of water at the roots it grows vigorously, and soon makes a dense mass. When grown in pots it is indispensable that it should have plenty of root-room and abundant and continuous supplies of water, even during the winter, when the fronds have all died off. In the case of pot cultivation a compost of three parts

of peat and one part of fibrous loam is that which produces the most satisfactory results. Though sometimes propagated by the division of its crowns in early spring, the *Osmunda* is more generally raised by means of spores, which ripen in July or August, and which, if sown at once, germinate freely, and, if grown in a cool pit or in a greenhouse, form young plants in a short time.

—Though the Royal Fern loses its fronds in early winter it ought never to be allowed to become quite dry at the roots, and the withered leaves should be permitted to remain as a protection for the tender growths in spring. *O. regalis* was formerly quite common in some districts of the Stewartry of Kirkcubright, more especially near the sea, but it has been practically eradicated by so-called collectors—a fate which has also befallen the rarer and more delicate *Hymenophyllum*.—W. McG., *Balmac*.

NOTES AND REPLIES.

Nephrolepis exaltata.—Despite all the recent introductions, I hold that *N. exaltata* is one of the most useful of the family. It is especially adapted for use as a basket or hanging-basket. If used as a basket plant, *N. exaltata* may be associated with *Ficus repens*, which will furnish the basket until the strong, erect fronds assume the drooping habit which follows as growth matures.—KIBK.

ROCK, ALPINE, BOG, FERN, AND WATER GARDENS.

ROCK GARDENS.

MISTAKES in the construction of these are often ludicrous. I came across an instance the other day of misplaced zeal in this direction. A short, slightly curving drive about thirty yards long, leading to the front of a house, was flanked on either side by a few trees in the background, faced by some very much neglected shrubs. A new tenant had the shrubs cleared away, and, instead of trenching the ground and planting it with a few choice things, has built up a rough perpendicular wall about 2 feet in height on either side next the drive, and another wall 3 feet inward from the first, the intervening space being filled with soil and planted with Wallflowers, Daisies, and the like. I should hardly think any attempt will be made either to plant among the stones or have anything to hang over and partially clothe them, so one is faced at the entrance with the two stretches of bare, ugly stones. Bareness is also often a striking—perhaps the most striking—feature of many so-called rock gardens, the area covered by the plants bearing a very slight proportion to the great masses of stone. All plant lovers admire and appreciate a well-made, well-covered rock garden, but it is certain that this branch of gardening is getting a little overdone. Looking at the matter more especially from the view of the owner or tenant of the small garden, it is certain, so far as flowers are concerned, that one has to consider how to get the best and most enduring display in the garden and for cutting at a minimum of labour and expense, and this can be best effected by the utilisation of the best hardy border plants, not by building expensive and too often grotesque rock gardens. E. B. S.

Hardwick.

NOTES AND REPLIES.

Geranium striatum.—I agree with all that "N. L.," page 570, says regarding this *Cranesbill*. Its only fault is its very encroaching nature; indeed, in a small piece of rockwork it has practically ousted everything else, the smallest piece increasing at a very rapid rate. By the way, I wonder if "N. L." has noted the fine "autumn tints" assumed by the foliage late in the season.—W. McG.

INDOOR PLANTS.

PHYLLOCACTI.

WITHIN the last few years there has been a considerable revival in favour of these showy-flowered, easily-grown plants. To the amateur with but a single greenhouse, provided a minimum winter temperature of 50 degs. can be ensured, these Phyllocacti have much to commend them, for such constant attention as is necessary in the case of many plants may be dispensed with in their case. Generally speaking, shading is not required except during the flowering period, as direct sunshine at that time tends to lessen the duration of the blossoms. In the dwelling-house a sunny window just suits their requirements. The period of blooming of most of them may

April and continue growing until August. They should be repotted, if necessary, after flowering. During growth the plants should be kept fairly moist at the roots and syringed overhead once or twice a day in hot weather. They like full sun, plenty of fresh air, and a temperature not less than 65 degs. at night. When growth is finished the plants should be kept dry and allowed more air. From the end of October to the beginning of March they may be stood in a light, airy greenhouse with a temperature of not less than 50 degs. and be kept dry, though not so dry as to cause the shoots to shrivel.

NERINES.

ONE of the brightest features at the meeting held at the Horticultural Hall on October 24th was furnished by a number

now known as *N. curvifolia major*, and *N. corusca* must on no account be omitted. They both flower somewhat earlier than many of the newer forms. A section that I do not care for is that in which the flowers are more or less of a leaden hue. Of white-flowered kinds some good forms have been shown, but the principal white that can be obtained from ordinary trade sources is *Nerine flexuosa alba*. In this particular kind the segments of the lower part of the flower are widely removed from those of the upper, and thus, as it were, form a lip to the bloom. In this the segments are undulated in a remarkably pleasing manner. The

CULTIVATION of these Nerines in pots is not at all a difficult matter. The fact that they resent being disturbed at the roots more than is absolutely necessary should be borne in mind, therefore the potting compost should be of a good, lasting nature. Manure, with its attendant risk of worms, should be avoided. The most suitable compost consists mainly of good yellow loam of a fairly holding nature, lightened to the necessary consistency by a mixture of silver sand. If the loam is too heavy it may have a little well-decayed leaf-mould mixed with it, but, if possible, I prefer to omit this last-named. The pots must, of course, be effectually drained. It should be borne in mind that Nerines are essentially greenhouse plants, though on this point opinions seem to differ, for I read in a contemporary under the head of "Gardening for the Week" that "when Nerines have done flowering, leaf-growth should be encouraged by frequent applications of liquid-manure. The plants should be kept growing in a temperature of 60 degs. at night till growth again stops, when cooler and drier conditions are necessary." I consider that a minimum temperature of 60 degs. would have a weakening effect on the constitution of the plants, and I would much prefer 10 degs. less. A very essential point in the successful flowering of Nerines, especially those of the Fothergilli section, is to take care that they have a good roasting in the sun during the summer. At that time no water will be needed till the flower-buds are seen. The possibility of a hardy race of Nerines has of late been brought forward, for under conditions such as the Belladonna Lily delights in, *N. Bowdeni* has proved very satisfactory at Kew.

W. T.

NOTES AND REPLIES.

Zonal Pelargoniums.—These are a valuable addition to the stock of flowering plants at this time of year, and, when well grown and flowered, make a fine display. To have them at their best they need a house to themselves, a low span-roofed structure being more suited to their requirements than any other form of house. If heated sufficiently to command at all times a temperature of from 50 degs. to 60 degs., so that air can, in moderation, be admitted night and day, they will keep blooming for a long period. If a water-tank is situated under the staging it should either be covered over or emptied for the time being, as moisture in the air quickly brings about decay in the trusses. A mild dose of Clay's fertiliser every week not only prolongs the blooming, but serves to intensify the colour of the flowers and increase the size of the individual pips.—K. P.

Potting up Wallflowers.—Owners of greenhouses—especially cold houses—do not always make the best use of them in the early spring months, not a few people confining their operations to a summer display. It is within the province of everybody with a greenhouse to have a charm-

A seedling Phyllocactus.

be set down as during the months of May or June. Cuttings are not at all difficult to root if side-shoots from 4 inches to 6 inches in length are pulled out of their sockets with a side twist, and inserted into well-drained pots filled with a mixture of loam and sand, lightened, if the loam is very heavy, by a little leaf-mould. Enough water should be given to keep the soil slightly moist, but an excess must be guarded against. In potting, the basis of the soil must be good loam with a mixture of sand or brick rubbish and a little well-decayed cow-manure in a dried state. The first half of the summer is the best time for taking the cuttings, as by so doing they will be well rooted before winter.

When coddled, over-watered, and often shifted into larger pots, Phyllocacti soon get into bad health and never flower. The plants commence to make new growth in

of flowering examples of Nerines. Within the last decade or two there has been a considerable revival in favour of Nerines, and great numbers of seedlings representing almost every possible cross have been raised. Many have during this period been given Awards of Merit at the various autumn meetings of the Royal Horticultural Society. The different forms now in cultivation vary in colour from white to deep crimson, numerous intermediate tints being freely represented. Though some of the rosy shades are very beautiful I must confess to a liking for the brightly-coloured kinds. Of them the scarlet and vermilion tints, particularly those whose petals are studded with jewel-like coruscations that differ in appearance when viewed from various standpoints, appeal most strongly to me. In any selection of the best the old *Nerine Fothergilli major*,

ing yet cheap display by the beginning of April by potting up Wallflowers. This can be done almost at any time now, when weather permits, lifting each plant separately with a good ball of soil. A 6-inch pot is a suitable size. Water well after potting, and let the plants stand out of doors for a few days before bringing them indoors. Air must be admitted to the house freely. When showing bud it improves the blooms very much if they are given weak liquid manure. Blood Red, Purple Queen, Orange Bedder, Fire King, and Primrose Dame are all well known and excellent sorts, being not only valuable for their rich colours, but for their delightful fragrance. These qualities are never more appreciated than when the plants can be had in bloom some few weeks before they flower out of doors.—W. F. D.

Perpetual-flowering Carnations.—Plants which were rooted from cuttings and potted off a few weeks ago have now been placed on a shelf near to the roof glass in a light, airy house. For the next two or three months top-growth will be slow, but the plants will be making roots, and at the turn of the year it will be found that the young shoots will develop satisfactorily. The foliage should not be syringed during the winter, nor must the roots be allowed to become sodden. The flowering plants are now at their best, and are producing large quantities of blooms. To enable the blooms to last in good condition as long as possible every precaution is taken to prevent the atmosphere of the house becoming very damp. The temperature at night is maintained at 50 degs., a little air being left on unless there is severe frost. Abundance of air is given on all favourable occasions. Watering is done as early in the day as possible, and an occasional application of an approved fertiliser afforded the plants.

Greenhouse climbers in winter.—To admit all the light possible to greenhouses in winter can only be achieved where climbing plants cover the roof by reducing their growth to a minimum. Some plants, like Passifloras, for instance, are so rampant that it becomes needful every year to use the knife in no unsparing manner if the plants on the stages below are to be given a proper chance. In summer, with sunshine to obscure, it is different, but in these shortened days one can only save the daylight by wielding the knife.—W. F. D.

Fuchsias—keeping them in winter.—Very often the plants have to be moved from the stages to make room for other subjects in bloom or for the accommodation of bedding plants, and sometimes they are crowded together under the stage close to the hot-water pipes, where, if they do not become dried up, they are forced into growth long before it is necessary. The coolest part of the house should be assigned Fuchsias, and, failing this, they ought to be put into a spare room or shed away from frost.—TOWNSMAN.

House-warming in Korea.—When a Korean begins to build a house he first lays down a system of flues where the floor is to be. These flues begin at a fireplace, usually built in an outer shed connected with the house. From the fireplace the flues branch out like the ribs of a fan and end in a trench at the back of the floor space. This trench, in turn, opens into a chimney, usually built at some distance from the house. When the flues are completed the builder carefully covers them over with flagstones; he then cements the whole floor and covers it with a sort of thick oiled paper for which Korea is famous. The rest of the house is then built round the completed floor. When it is time to cook the rice for the morning meal the wife lights a little straw or brushwood in the fireplace in the shed. While the rice is cooking the heat from the fire passes through the flues, heating the stone flags of the floor and diffusing a pleasant warmth that lasts until it is time to prepare the next meal. Two heatings a day suffice to keep the floor warm.

GARDEN FOOD.

NUTS AND THEIR VALUE.

WHEN considering the question of food-values and their relations to expenditure there is much to be said in favour of Nuts, which contain a large amount of protein matter and are also, if used in the right way, able to afford a supply of necessary oil. Housekeepers of experience know that to spend less money on food does not necessarily mean economy, and if Nuts are to form an occasional substitute for meat they must be used fresh—when they contain the largest amount of oil—and they must be presented in suitable form if they are to be digestible. Towards this end purchase a small mill—the cost of which is very trifling—in order that the Nuts used may be freshly ground, and have them slightly roasted before grinding. Thus they will have a better flavour and more food-value than when bought in ground form.

NUT AND POTATO RISsoles.—Take 2 teacupfuls of cooked Potatoes, 1 teacupful of mixed Nuts, 1 egg-yolk, a tablespoonful of white sauce, salt and pepper to taste. Have the Nuts lightly roasted in the oven; then put them through the mill or chop them finely. Rub the Potatoes through the sieve, and mix them with the Nuts. Add seasoning to taste, and then mix in the egg-yolk—keeping back a little with which to brush over the rissoles—and bind together with the sauce. Turn the mixture on to a plate and let it cool. Now form it into balls on a floured board; egg and breadcrumb these, and fry them in hot fat. Drain them and serve with good meat-gravy.

CHESTNUTS IN BROWN SAUCE.—Owing to the large amount of starch they contain Chestnuts should always be well cooked. If nicely boiled, then tossed in a little fat, and seasoned with salt and pepper, they make excellent substitutes for Potatoes, crops of which have been very disappointing in some districts this season. Prepared as follows Chestnuts make a very good stew: First remove the outer shell and the inner brown skin of the Nuts by making a slit at the side of each with a sharp knife to prevent bursting, and then put them on a tin in the oven for eight or ten minutes. Now take out a few at a time, and remove the skins with the point of a knife. Care must be taken not to have the oven too hot, or the Nuts will brown, which is undesirable. Have ready half a pint or more of ordinary brown sauce, put the prepared Chestnuts into this, and let them stew very gently until tender.

BAKED NUT SOUFFLE.—Into a saucepan put half a teacupful of breadcrumbs and a cupful of milk, and cook over the fire until quite smooth. Then remove the pan from the fire and to the contents add a cupful of mixed Nuts, chopped finely; a small stick of the white part of Celery, finely chopped; a teaspoonful of minced Parsley; and pepper and salt to taste. When well mixed stir in the beaten yolk of an egg, and then fold in lightly the whisked white. Pour the mixture into a greased pie-dish, sprinkle the top with ground Nuts, and bake in a moderate oven for about twenty minutes. Serve as quickly as possible.

NUT ROLY-POLY.—Take $\frac{1}{2}$ lb. of flour, a teaspoonful of baking-powder, 2 oz. of Nut butter, a pinch of salt, brown sugar, mixed Nuts and raisins. Have the raisins and Nuts well chopped. Rub the butter into the flour, add a pinch of salt, the baking-powder, and sufficient water to make a smooth paste. Roll this out into a sheet a quarter of an inch in thickness, cover first with a layer of sugar, and then with chopped Nuts and Raisins. Roll up, brush over with sugar moistened with milk, and bake in a moderate oven.—Guardian.

Tomatoes—keeping powers of fruit.—When these are cut just as they are commencing to colour they will keep a long time. Such fruits, however, are poor in flavour and not to be compared to those ripened on the plant. The best flavour can only be obtained by allowing the fruits to hang till dead ripe. Having some

fine fruits under glass in a cold house this autumn, I allowed them to remain on the plants, and was astonished at the time they hung after being coloured. When used they were delicious. Many people do not know the true flavour from having to obtain them from shops. When cut in a green state they will keep for two months if needed.—W., Surrey.

GREEN INDIAN CORN.

I do not know the exact age at which green Corn or Maize should be gathered, but the right time is when the grains are fully grown, but still full of a milky substance, which, when ripe, hardens into the Maize of mature growth. The most delicious way of cooking green Corn is to gather the cobs, remove all the outside sheath, leaving just one or two leaves to cover the grains, and boil until tender (the grains, not the centre) in salted water. The cobs should be placed in water when it is boiling fast, and the water should boil briskly during the whole process. Take up the cobs, remove the leaves, and send to table very hot. The usual way to eat is to take up the cobs with a napkin and eat off the grains. But the nicest way, to my thinking, is to hold the cobs upright, and, with a sharp knife, cut off all the grains. Pour a little dissolved butter over, and sprinkle with salt.

The simplest way of cooking any vegetable is always the nicest, to my way of thinking, but green Corn can be used to make very delicious dishes. One dainty way of cooking it is to take a cupful of the green Corn after it has been boiled and cut off the cob. Pound in a mortar until it forms a paste, add sufficient pepper and salt to flavour, and one tablespoonful of flour. Beat two eggs well and mix with the rest of the ingredients. Fry in spoonfuls in butter, drain on kitchen paper, pile high on a serviette, and send to table very hot. A sprinkling of chopped Parsley makes a pretty garnish. H. T. C.

NOTES AND REPLIES.

Apple Allington Pippin a failure.—This with me is poor, not a keeper and not a good quality Apple, compared with our best. Why should such a fruit be brought out in the face of such as Sturmer, Ribston, Roundway Magnum Bonum, Blenheim, Cox's, or D'Arcy? The truth is, the growth in market quantities of our best native Apples is a far more important affair than buying novelties that often prove failures. The trade should be more careful, and certificates to fruits should not be given until a fruit has been tried for at least ten years in gardens.—W.

Italian Chestnuts.—Mr. N. Lewis Solomon writes me from Covent Garden:—

“I am afraid the large Italian Chestnuts are not coming this year. The growers say that they are required at home for food, and therefore will not allow them to leave the country. Whether this is right or not I cannot say, but up to the present no Italian Chestnuts have been seen on the market. I have sent you the next best, and hope you will like them.”

THE Roman soldiers, who made such wonderful roads and carried a heavy weight of armour and luggage, lived on coarse brown bread and sour wine. They were temperate in diet and regular and constant in exercise. The Spanish peasant works every day and dauces half the night, yet eats chiefly black bread, Onion, and Water Melon.

IRISH agricultural returns for 1915-16 show a decrease of 10,092 acres under Wheat, 17,071 under Oats, 831 under Rye, and 66 under Beans and Peas, while there has been an increase of 8,477 under Barley and Bere. Green crops decreased 22,335 acres, and fruit 318 acres, but Flax increased 38,311 acres.

OUTDOOR PLANTS.

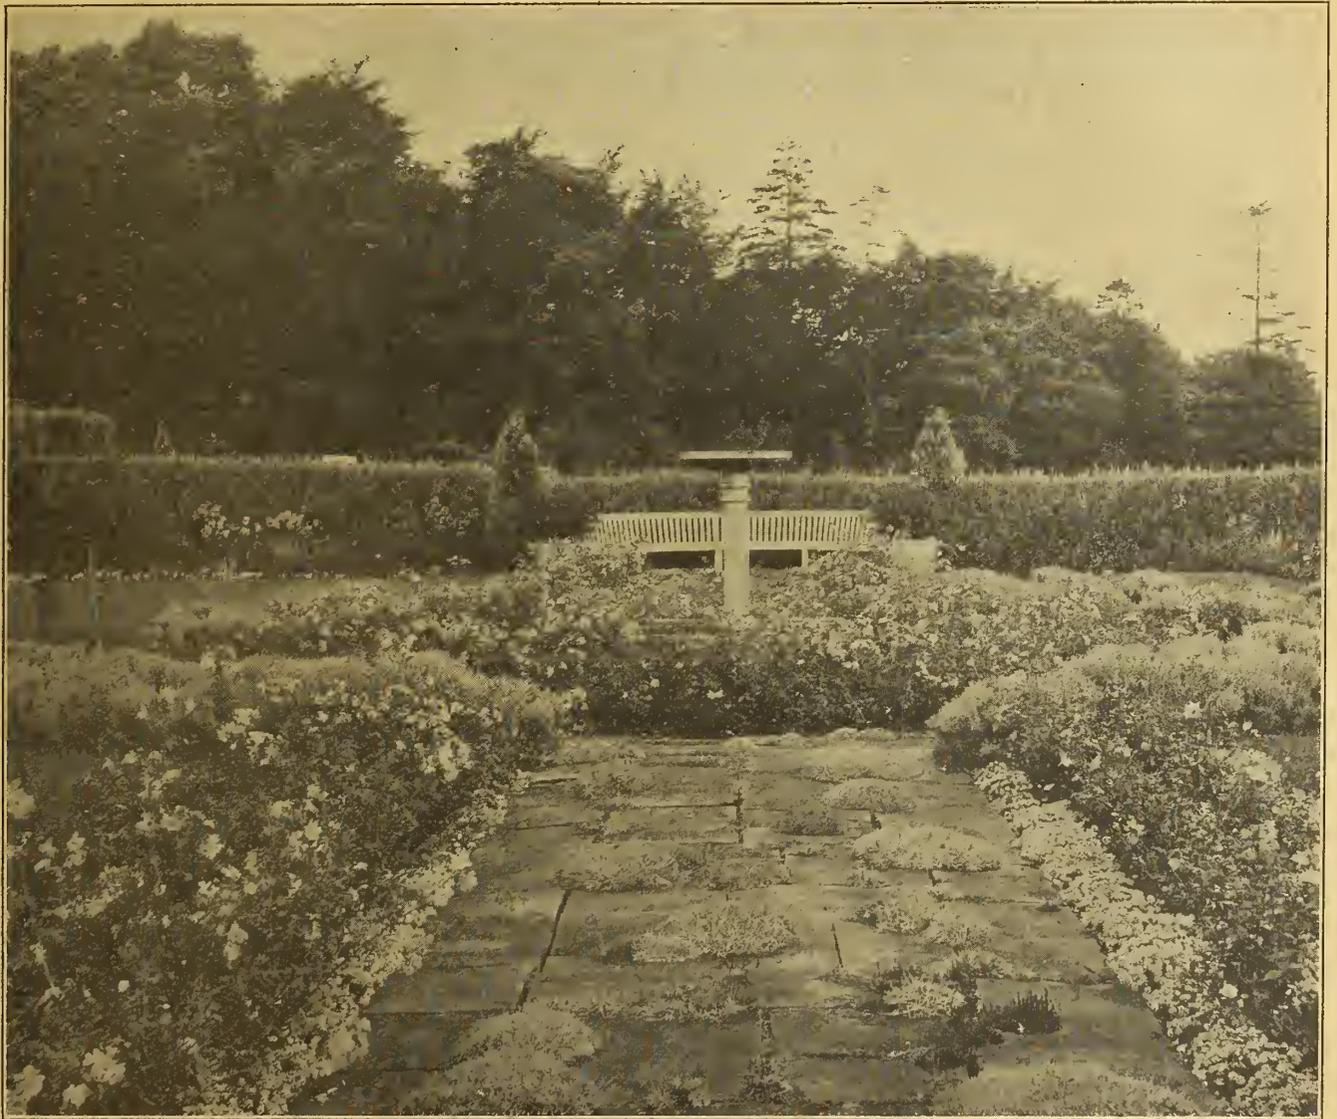

THE FLOWER GARDEN AT EMMETS.
This is one of the pretty incidents at Emmets, and there is no reason, however, for calling it a formal garden, as is the new and silly way nowadays. The garden is right in all ways, though I do not think the clipped hedge is the best thing for surrounding it. It would be as easy to get a fence that did not want clipping, and a wall of some local material would be as pretty as anything, or, next, a good Oak post and rail fence would be right and graceful with climbing Tea Roses and other climbers, and would get rid of the

is necessary. It is a showy Sage from Kashmlr, whence it came more than eighty years ago. It sends up a spike bearing a number of whorls of flowers. Of a beautiful blue, and as the spike is 2 feet or more in height, *S. hians* is a capital plant for the border in June. It is hardy and lends itself readily to ordinary border culture.—**S. ARNOTT.**

AMONG THE HARDY FLOWERS.

CUTTING DOWN HARDY FLOWERS IN AUTUMN AND WINTER.—This, it appears to me, offers a most useful question for our consideration. The garden should be kept as neat and tidy as possible, compatible with its style, even the most informal garden look-

OLD FOLIAGE ON THE BLUE AFRICAN LILY.
—I have tried leaving on this the old leaves until late spring after the young growths had pushed through the old, and I find that they are an excellent protection. It is claimed for it that it is the natural one, but that, I should say, is not a conclusive argument, seeing that the conditions in our country are absolutely different from those in its native land. However, if we find it answer for our purpose it matters little whether it can be defended on such grounds. Last spring, I thought when the frosts of any severity were over, and the new growths of the African Lily had grown through the old, pulp-like leaves, that they, in turn, were

Flower garden at Emmets, Kent.

barber's clipping, always a mistake. I never clip anything in my own garden. What is meant is that a clipped line of shrubs is a dead line, involving much annual labour and giving nothing back, whereas a low wall of local stone may be a garden of choice plants that want a little more warmth than our climate gives in the open ground. **W. R.**

Salvia hians.—As a good June-flowering, hardy border plant *Salvia hians* deserves attention. It only appears to have one defect. This is that it produces few flowers for the size of the plant. It is possible that frequent division may be necessary, but *Salvia hians* is not yet common in cultivation, and some experience

ing as if robbed of some of its charm if it is neglected and unkempt even in the depth of winter. But it is a question if we do not sometimes carry this too far, particularly in the colder districts, where the spring frosts are severe and often do harm to the young growths of certain plants. One of your contributors has drawn attention to this subject and has mentioned several plants which he does not recommend should be cut down in autumn and winter, but allowed to retain the old stems, etc., until the young shoots are well through and hardened off. It cannot be denied that old stems and decayed leaves are not specially pleasing, to say the least of it, but we must put up with a good deal to obtain better results.

injured by frost. I was in despair, thinking the plants would do no more good. I left them alone, however, and, to my delight, new leaves again appeared and the plants flowered splendidly in due course. It is contended that this is much better than covering with straw.

COVERING OTHER PLANTS.—I have also been trying other and hardier plants, and I find that the old stems, if left until new growth has taken place, afford an excellent shelter, not only for the young shoots, but also give some needed shelter to many very early flowers which are apt to be nipped by late frosts. These old shoots are untidy—there can be no denying this—but it is worth considering whether the gain is not greater than the loss.

TENDER CLIMBERS ON WALLS.—I find that covering these with a close mat, as is so often done, is very risky if we have sharp frosts after the plants have made some growth. In winters which are mild in the early part (and we have many such) growth is fostered by the covering of the mat, and if we remove the latter too early there is always the risk of frosts destroying the young growths, made tender by their covering and stimulated by the warmth the mat affords.

TORCH LILIES IN SPRING.—It is curious how badly Torch Lilies suffer in some springs in certain gardens. In many seasons they suffer a good deal if left unprotected. Some folks put ashes or litter over the crowns, while others tie the old leaves together so as to throw the winter rains and snow off the crowns. This is all very well if there are not many late frosts, but I am not sure that this tying the old leaves like a sheaf over the crowns is a good plan. The other winter I lost some plants through doing this. It was rather a mild spring, and when I examined the plants I found that they had made some growth. I removed the old leaves, and the growths were coming on nicely when a "killing frost" came and the plants were so badly crippled that they did not recover. Those with litter over the crowns survived.

AN AMATEUR OF HARDY FLOWERS.

HERBACEOUS PLANTS FROM SEED.

ALTHOUGH in the majority of places little attention is given to raising a stock of herbaceous plants in any variety from seed, it is a question if it is not a branch of flower gardening that does not deserve more attention. One is sometimes met with the argument that we have plenty of bedding plants for the formal garden, and many herbaceous plants are short-lived so far as their flowering season is concerned, and are, therefore, hardly admissible in prominent places where a good and constant supply of bloom is required for a given time. This may be partly true, but in the case, for instance, of Antirrhinums, Pentstemons, Carnations, Violas, etc., we have even a longer flowering season than is obtained from the majority of tender plants; whilst others that are more quickly out of flower, as Pyrethrums and Columbines, are beautiful in their foliage, and may, at any rate, be planted sparingly in clumps with other things. Take also the case of herbaceous borders. Are they full of good things, or is there a mixture of weedy rubbish and a lot of shrubs and small conifers that are quite out of character on such? If so, by all means (as excellent strains are obtainable from all the best firms) secure packets of seed of such things as Poppies, Pyrethrums, Carnations, Polyanthus, Antirrhinums, Pentstemons, Foxgloves, Aquilegias, Campanulas, Verbascums, and Delphiniums that will in their respective heights furnish a grand display. Even if not wanted for flower garden planting they are sure to be useful, and in all cases where there is a great demand for cut flowers never be without a nursery bed of perennials. A small stock in variety once obtained, the best seedlings can be selected for future seed saving and sowing. Fortunately, too, in the case of the majority of hardy plants one is, with careful selection, fairly certain of a good plant, good average flowers, both individually and in the spike or truss, and occasionally some interesting new departures. All species that will flower the same season should be sown early, say about the end of February, either in a pit or, preferably, in boxes, placing the same in a vinery that is at work not too far from the glass. Those who are contemplating raising a stock of such plants

should not attempt more in the spring than they can well manage. If other work press rather hard it is best to defer the sowing until the end of the summer, transplanting and planting out in the following spring. E. B.

ENGLISH AND SPANISH IRISES.

Too frequently the importance of planting these in due season is by no means fully appreciated, and so long as the bulbs remain apparently sound in the dry state, planting is deferred and often neglected. But if those that remained undisturbed in the ground were examined, it would be found that several inches of new roots had been produced even as early as the beginning of October. This alone should prove that too long a season of dryness is not desirable or even necessary. Frequently when the resting is enforced beyond reasonable limits a dry rot sets in that plays havoc in a short time. This is true of the English section so-called more than of the Spanish in my experience, and may in some degree possibly owe its origin to an imperfect system of drying after lifting the bulbs. Indeed, once thoroughly dried, I find they are safer stored in perfectly dry sand in shallow boxes in a well-ventilated place rather than exposed to the fluctuating influences of weather and consequent atmospheric changes. Completing their flowering and growth by the middle of July the period of rest immediately ensues, while during autumn and winter they are quite active at the root. In the case of heavy soils and such as are cold I believe in a short rest each year as a preventive of deterioration of the bulbs. To this end I would lift them, if possible, any time after the middle of July and rest them for six or eight weeks. Failing this, place lights over the beds and rest them in this way for at least ten weeks.

As pot plants these lovely Irises do not receive much attention. While not capable of enduring anything approaching a forcing temperature, they may be forwarded in pots in a greenhouse quite easily. Under this treatment the exquisite beauty of their flowers is enhanced. Any required for this purpose should be potted early in autumn and remain plunged 6 inches deep in ashes or Coconut-fibre till the end of February, or they may be introduced at the beginning of this month into a cold-house and brought on gradually. The Spanish section being the earlier are better for this purpose, and of these some of the pure white kinds are lovely. From the moment growth commences plenty of water will be needed at the roots. H.

NOTES AND REPLIES.

Romneya Coulteri.—What is the proper treatment for this plant? Do I cut it down to the ground in the same way as other herbaceous subjects? I should also like to know whether it can be propagated by means of side shoots or cuttings. Any information will be greatly appreciated.—G. H. S. R., Bristol.

[This is quite hardy in warm soils, and in your district you should have no trouble with it. Where it will not grow in the open it would do so in many places against a wall with a southern aspect. When once planted it is very averse to root disturbance, often dying, even though well cut back. Planting should always be done in the spring just before growth commences. It is also advisable to procure a plant in a pot. A little protection over the roots, such as rough Cocon-fibre, is advisable during the winter. During severe weather a mat may be placed over the branches, removing this directly the weather becomes warmer. It can be increased from root cuttings. You might during the dormant season take up a few stout roots from

established plants—if you have such—cut them into lengths of about 2 inches, and dibble them into sandy soil in a pot or deep pan. They should be put in in such a way that the top of the cutting is about half an inch below the soil. These root cuttings need to be kept in a frame where they are quite safe from frost and be watered when necessary.]

Spanish Irises and lime.—I was interested in reading your notes re "Iris not flowering," in October 28th issue, and should like to know if *Iris hispanica* requires lime or basic slag, and, if so, what quantity? Some of the blooms are very short in the stem—i.e., 3 inches to 4 inches—whereas they should be from 12 inches to 18 inches long. I have given a light dusting of soot over the beds as the slugs eat the foliage when it comes through the soil. Please state at what season the lime would have to be applied.—S. J. HUBERT, Guernsey.

[All the "Bearded" or "Flag" Irises are partial to lime, and it was to a variety of this set that reference was made in a recent issue. Those of the Spanish set usually grow freely enough in all light, loamy soils, and often also those of medium texture. If lime is required by the soil it should have been added prior to planting, and in the case of very light, sandy soils, which are usually deficient of lime, a dressing would be helpful. It should be, however, incorporated with the soil for the benefit of the roots and plants, and surface dressings of either this or basic slag would avail but little. The latter, too, is very slow of action, and results are not quickly apparent. If we understand you rightly that your Spanish Irises attain only 3 inches to 4 inches high at flowering time something more than you have told us is wrong with them. How long have they been planted, and at what depth? What is the nature and depth of the soil? Cannot you send a bulb or two for our inspection? In your favoured locality we should have expected they would have been in the nature of weeds. You had better send us fuller particulars.]

Weeds in drive.—Can you tell me the best and quickest method of getting rid of Grass—a heavy crop—on a neglected drive? Would weed-killers act at this time of year, or what would? Labour to weed it is impossible to get?—S. B., Newbury.

[There will be no difficulty in clearing your drive with a good weed-killer, such as can be had from Bentley, Hull. Apply it very carefully so as not to let it come near any plant to kill it. It will not only clear your drive of Grass and weeds, but will leave it in better condition than any other way of clearing would do.]

Staking hardy plants.—Some years ago, when in charge of a large garden in the West, I grew hardy plants largely. Having a long border within sight of the Abbey rooms many things had to be supported. From the first I did this by using strong Pea-stakes, according to the height of the plants. During the twenty years I lived there nothing but these were used. Stakes were placed amongst the growths, and, if necessary, a thin bit of raffia was tied round them to keep the shoots in place. When at Hampton Court in the summer I noted in many cases that one stick was used to each shoot, taking three times the labour and looking very stiff. Now the winter is with us those who have not adopted this method should prepare their stakes.—J. CROOK.

Asperula hexaphylla.—Looking through the hardy-flower borders the other day, I was reminded that the present is a very good time to increase the stock of this useful Woodruff. Flowering as it does in May and June, its light and graceful panicles are valuable for associating with the earlier Sweet Peas, and it fills a gap until the more generally used Gyp-

sophila paniculata is available. *A. hexaphylla* is readily increased by division, and is not without value in the rock garden as well as in the border.—KIRK.

DIERAMA (SPARAXIS) PULCHERRIMA.

DIERAMA PULCHERRIMA appears to do well in a light and gravelly soil, though it is said to prefer plenty of moisture. The

Dierama (Sparaxis) pulcherrima. From a photograph sent by Mr. S. G. P. Hutchinson, Castle Lough, Nenagh, Co. Tipperary.

plants are very difficult to move, and it is best to sow the seed where it is required permanently. Plants grown from seed sown four years previous had flower-stems up to 8 feet high. The graceful bell-like flowers on slender but strong stems vary greatly in colour, from almost white, through various shades of pink, to a dark maroon. Self-sown seedlings have sprung up in quantities, and there are many patches of them one and two years old.

Tipperary. P. H.

OURISIA COCCINEA.

MR. CORNHILL writes (page 570) that he fears the "position of this plant at Wisley would be no guide to him." One would have thought that so signal a success would have been of the greatest help to anyone, more particularly those who, like Mr. Cornhill, have experienced little but failure with the plant. Your correspondent quotes an experienced hardy plant grower who said: "You can do what you like in the way of soil, but you cannot make an atmosphere." The idea is quite wrong. The very rocks and sheltering background, in the case of the Wisley group, create an "atmosphere" of the highest importance—virtually an essential—and were these same plants bereft of it, were they taken up, divided, and planted out in full exposure in the hot, sandy soil obtaining, their failure would soon be as complete as their success is now evident. Rocks and sheltering background, however, need not in every garden be slavishly imitated in order to secure success with *Ourisia*, though the recognition of all these mean much to the plant, and the adoption of the nearest possible equivalents will assuredly pave the way to ultimate success. To ignore them, or be studiously blind to all that they would convey because we do not all happen to have a Wisley to toy with, or the belief that there is some subtle influence in the place not available else-

where, are not likely to lead anyone to success. The spirit that succeeds is that shown by "North Yorks," who (at page 553) writes both interestingly and instructively of "Plant Vagaries." Failing five years in succession, failure is at length turned into complete success by the simple expedient of "a lump of rock in front of it." That "lump of rock" created the "atmosphere" the *Ourisia* needed. In-

identally the experience of "North Yorks" is a complete endorsement that the *Ourisia* may be "lifted and divided"—a matter concerning which both Mr. Arnott and Mr. Cornhill appear so fearful—with impunity. The value of experience so gained cannot well be over-estimated, while the pleasure and satisfaction of conquest are considerable. Mr. Cornhill enquires why did I "not plant out at once in the open ground instead of nursing the divided portions in a frame." The answer is, that I did not desire to court failure. My bit of garden soil to-day is sandy Heath soil, in summer time powder-dry, and I would as soon think of planting in this as throwing the pieces into the dustbin. Moreover, they were not "divided portions," as Mr. Cornhill, for his own purpose, continually asserts, but pieces of the extending rhizome just beginning to root. Knowing my subject, I potted and put them into a frame. In other words, by creating an "atmosphere" to their liking, I gave them the chance of doing, and results have fully justified it. Mr. Cornhill further remarks that my "instructions" might be "acceptable to inexperienced amateurs," ignoring the obvious fact that so far as this *Ourisia* is concerned he is as one of the most "inexperienced," having nothing but failure to record. He is a little unreasonable, too, in expecting me to divine the cause of his failure, since all I know of the circumstances is from a line or two of letterpress. The most interesting part of Mr. Cornhill's note is the final sentences, his remarks going to show that he has been sufficiently impressed with what I have written that he is attempting an imitation. My only wish is that he will succeed and realise some of the beauty this brilliant *Ourisia* has to give. E. H. JENKINS.

Hardy Dahlias.—Some time ago a query appeared in GARDENING ILLUSTRATED con-

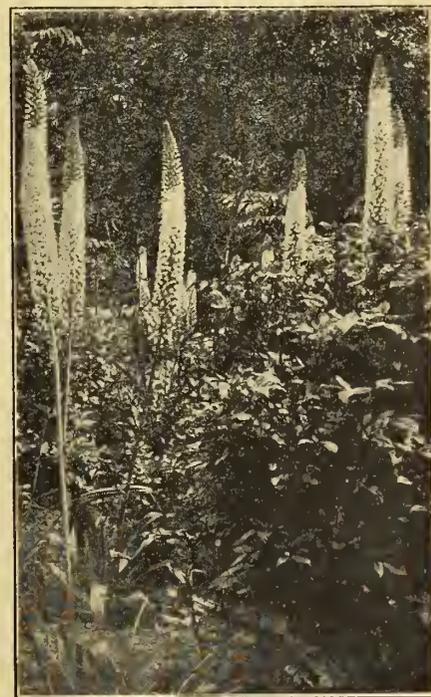

cerning a hardy Dahlia. I am not aware that the Dahlia, strictly speaking, can be considered hardy, but in some favoured places it may be said to be practically so. In these gardens there are many roots of Dahlias which are never lifted—especially some of the Paony-flowered section—and which, year by year, increase in size. One plant of *Souvenir de Gustave Duzon*, a giant-flowered variety, has stood the winter for ten years, and was over 7 feet high and covered with bloom during the present season. *Pompon* and *Cactus* varieties, too, have been left in the ground for a series of years without damage. Of course, our climate is comparatively mild.—KIRKCUDBRIGHT.

Galtonias.—When planting bulbs in autumn consideration is mostly given to those that are intended for a spring display, others, whose time of blooming is in summer, not being taken into account. One such bulb that may be planted now—when weather admits—on sheltered borders is the *Galtonia (Hyacinthus) candicans*, whose tall, stiff stems are laden with ivory-white bells in July. If planting is deferred until spring, they bloom somewhat later.—TOWNSMAN.

Erysimum Golden Gem.—Already (in mid-November) the yellow flowers of this neat *Erysimum* begin to be noticeable, and will continue throughout winter unless very severe frosts are experienced. At one time, *Erysimums* used to be favourite plants for spring bedding, and, in view of their accommodating and hardy nature, it is strange that they have lost their popularity. *Erysimums* may be sown at the same time and given the same treatment as Wallflowers.—W. McG., *Balmac*.

GIANT ASPHODELS GROWN WITH SHRUBS.

THIS is an effect we lately saw at Kew, showing the spread of this good idea of

Giant Asphodels among shrubs.

growing these great plants with shrubs. They do better so and look better. The fault, if it be one, of these enormous plants is that they shrivel away after flowering, leaving blanks which one cannot always easily fill. Therefore the association with them of hardy shrubs is right in every way, and the soil that suits the one suits the other.

VEGETABLES.

A NEGLECTED GARDEN.

I HAVE taken a house which has been unoccupied for some time, and the garden has, consequently, been very much neglected. The soil is light on a gravelly subsoil, and for some years has had little, if any, manure put into it. There are a few winter Greens planted on part of it, but they are very small and stunted, and I understand the crop of Potatoes which was grown this year on most of the ground was but a poor one. I should be much obliged if you would advise me as to the best method of getting it back into good condition. (1) As farmyard manure is difficult to get, what would be the most suitable artificial to use, and in what quantities should I apply them? I have by me a small quantity of superphosphate, kainit, and sulphate of ammonia. (2) What vegetables suitable for my own household would do best on a soil of this description? (3) One part has been allowed to go out of cultivation altogether, and is covered with rough Grass, Thistles, etc. What should I do with this? Any advice you can give me will be much valued.—FARMER.

(1) As you cannot conveniently obtain farmyard manure, which is really what is required to restore the garden to a fertile condition, we think you cannot do better than give it a good dressing of basic slag and kainit. What we should recommend you to do is to bastard trench or double dig the whole of the ground, keeping the gravelly subsoil at the bottom and working in with it such material as garden refuse, tree leaves (which can now be had in quantity), or long stable litter. The artificials can then be utilised for the top spit, applying about 8 oz. of basic slag and 4 oz. kainit to the square yard, mixing them as intimately with the soil as possible. To be really effective, the slag, in particular, must be applied without further delay. If unable to obtain any of the materials mentioned to mix with the bottom spit, give that also a similar dressing of basic slag.

(2) On soil prepared in the manner described all kinds of vegetables should succeed, whether they be what are termed "stem" or "root" crops. Seeing the soil would, if the advice tendered is adopted, be stirred to a good depth, all kinds of root crops should do exceptionally well. For the same reason the roots of all other kinds of vegetables would quickly penetrate the top spit and descend to the lower one in search of food placed there for their benefit. It may be stated that vegetables grown under such conditions are not nearly so much affected by drought, as deep working of the soil prevents it from drying out so quickly as is the case when it is merely dug one spit deep.

(3) With regard to this portion of the ground, we advise that the top be pared off some 4 inches in depth and charred—not burnt—sufficiently to destroy all kinds of vegetation that it may contain, using the residue for mixing with the lower spit. If the charring is properly done, there should be a considerable quantity of material at disposal for the purpose named. The upper spit can then be treated to a dressing of kainit and basic slag, as advised for the other part of the garden. In February apply 2 oz. of superphosphate per square yard, and lightly fork it in, both in this and the previous case. Then after the various crops are above ground and growing freely, apply nitrate of soda or sulphate of ammonia to the surface at the rate of $\frac{1}{2}$ oz. per square yard, and hoe it in when possible to do so. This may be used every few weeks while the various crops are making growth, but the quantity used on each occasion should not exceed that named.]

Food production and the garden. — I was interested in a "Scottish Gardener's"

letter in your issue of October 21st, in which he points out that increasing the supply of foodstuffs in the garden often results in increasing also the waste—which, he says, exists more or less at all times—quoting, for example, the case of Peas, Cauliflowers, and Cabbages, which at times often turn in more rapidly than they can be consumed. May I suggest a remedy for this wastage which he may have overlooked, that is, to feed the superfluous vegetables to Belgian hare rabbits, and thus really increase the food of the country and keep the money now spent abroad on this article of food at home? Not only will the hares eat up greedily any garden produce going to waste, but when the outside leaves of Cabbages, etc., run short they are equally accommodating about finishing up the garden weeds, so that absolutely nothing is wasted. I think this should appeal to "Scottish Gardener."—L. BLACKBURN.

Earthing up Celery with ashes.—Few things cause more annoyance than to find that after all the trouble taken, from the seedling to the earthing stage, the greater part of what promised to be exceptionally good Celery is absolutely worthless, either owing to disfigurement by slugs, or the wholesale destruction of the hearts, caused by excessive moisture having enveloped these over a long period. The fact is well known among gardeners that slugs have a great aversion to finely-sifted coal-ashes, such as those from an ordinary kitchen grate, and when we remember that the addition of these, although adding but little to the manurial properties of the garden, render even water-logged soils workable, what possible excuse can there be against adding a goodly proportion to the soil it is intended to use for blanching? In case any timid reader may doubt the wisdom of using these, knowing the reputation coal-ashes have of imparting their somewhat objectionable nature to whatever is brought into contact with them, I may add that I have sometimes used these alone when blanching some of the finest Celery I ever grew.—F. R. CASTLE in *The Garden*.

Peas—a selection for a small garden.—Peas are amongst the most acceptable and profitable of vegetables, and in a small garden an endeavour should be made to have them for as long as possible. Here is a selection which has given every satisfaction during the current year and which I intend to repeat. For dwarf Peas I would advise sticks being used, to be put in either at the time of sowing or immediately they show above ground, as their use is twofold—they afford some protection in case of cold weather and the crop will be heavier, as, when once Peas are battered down by wind and rain, and lie on the ground, the yield is never so good as when support is given:—First Early: Dobie's Early Bird (1 foot); Thomas Laxton (3 feet). Second Early: The Daisy ($\frac{1}{2}$ feet); Duke of Albany (5 feet). Maincrop: The Gladstone ($\frac{3}{4}$ feet); Daniel's Matchless Marrow (5 feet). Late: Veitch's Perfection (3 feet); Sharpe's Queen (3 feet).—WOODBASTWICK.

Growing Peas and Beans in trenches.—The past season has again showed the great advantage of growing Peas and Runner Beans in well-manured trenches. Where this has been done the crops have been much heavier than where not so treated. The plan of growing in trenches, speaking from my own experience, is worthy of recommendation, especially where room is limited, and consists in digging out trenches in the late autumn 2 feet 6 inches deep and 3 feet wide, into which some good, rotted dung is placed

to the depth of 6 inches or 9 inches, covering this over with soil and allowing it to settle for several months, subsequently filling in with soil to within a few inches of the top of the trench. Before sowing, the surface should be well dressed with superphosphate, and it is well to remember that nothing whatever is gained by sowing thickly. When finished, the trench will be several inches below the ground-level, this enabling one to mulch with manure, Grass clippings, etc., in very dry weather. Beans, in particular, go far down for food, and, coupled with copious waterings, the yield is much heavier and of longer duration. The same remarks apply, to a great extent, to Peas, and no better time for getting on with the preliminary work can be selected than now. A good feeding-ground at the base, into which the roots can penetrate, is half the battle and goes a long way to guarantee a good and successional crop.—WOODBASTWICK.

Tomatoes from cuttings.—It sometimes happens at the fag end of the Tomato season that growers are tempted to use the plentiful supply of shoots as cuttings, thinking thereby, if they can but winter these, they will get an earlier crop the following year. This plan usually suggests itself in November when plants are being cleared out of the house to make way for other things, but experience shows how futile it is for the small grower to expect anything like satisfactory results. In the first place, although propagation may be effected quickly enough, it is the after-treatment the young plants have to undergo which militates against them. The heat and moisture required by other plants are prejudicial to young Tomatoes, which frequently become drawn and weakly, and are handicapped in the early months of the year through lack of vitality. By far the better plan is to sow seed in heat in February and secure a fresh stock, which invariably gives the best results with considerably less trouble.—LEAHURST.

THE WEEK'S WORK.

OPEN-AIR GARDENING.

IN BLOOM NOVEMBER 22ND.—*Solanum jasminoides*, *Clematis*, *Choisya ternata*, *Escallonia montevicensis*, *Veronica* (in variety), *Genista hirsuta*, *Parochetus communis*, *Aubrietia*, *Lithospermum prostratum* *Heavenly Blue*, *Iris stylosa*, *Sternbergia lutea*, *Violets*. The above are all in sheltered positions. *Jasminum nudiflorum*, *Laurustinus*, *Pampas Grasses*, *Ericas*, *Menziesias*.

THE WEEK'S WORK.—During the past week, there have been a fall of snow and much rain, which have made the ground sodden. Any planting of trees and shrubs not completed will be better deferred until February. Most herbaceous plants have been cut down to the ground level, the surface-soil pricked over with a fork, after which hills of ashes are placed around tender species as a protection against frost. The whole of the border will afterwards be afforded a mulch of leaf-mould. Kniphofias being somewhat tender, the tops of each plant are gathered together, twisted spirally, and tied in such a way that the growth centres are protected by the leaves. As a further precaution, a mound of ashes is formed round each plant. Tea Roses need some kind of protection in severe weather or they will be found very much weakened and sometimes killed outright. It is easy to avoid this by drawing around the base of the plants a mound of soil from the borders or beds, thus preserving from injury the lower buds, which will then produce strong flowering-shoots. Tea Roses start into growth on the slightest spell of mild weather, so that it is well to put off protection until severe frosts are feared. Wall climbers have again been looked over and made secure for the winter. Pruning for the most part is left until spring, merely thinning out crowded growths for the present. Anything of doubtful hardiness is protected by working in thinly among the shoots a few Spruce branches. These give all the protection necessary, and admit a fair amount of light and air, mois-

ture being dispelled more quickly than when closer protecting materials are employed. Excessive moisture during winter is disastrous to many plants. The plants of the Algerian Iris (*I. stylosa*) have been cleaned and the surface-soil stirred. A few blooms have appeared, and if the weather becomes milder they will soon be pushing up in great numbers.

Now that the leaves have all fallen a general clearing-up (as far as labour permits) will be made, the necessary quantity required for hot-beds and leaf-soil being carted to their respective places. It is a mistake to rake out shrub-beries, even though it be done for the sake of neatness. The fronts may be raked clear, but the leaves at the back and where they are not likely to be blown about should be allowed to remain. The rock garden is now being finally cleaned and put in order for the winter. It is necessary to remove all leaves, or as they decay there is danger of their rotting the smaller-growing plants. A good mulch of leaf-soil has been afforded tender subjects.

F. W. GALLOP.

Lilford Hall, Oundle, Northants.

SOUTHERN COUNTIES.

Libonias.—Plants in 48-sized pots are, when well grown, useful either for rooms or the greenhouse. They do best when accorded a trifle more warmth than an ordinary greenhouse affords. Too low a temperature leads to loss of foliage. The plants being abundant rooters, assistance in the shape of mild doses of liquid-manure to tide them over the flowering period is essential.

Poinsettias.—These must also have assistance in the same way, otherwise loss of the lower leaves is likely to ensue. Stimulants are also necessary to enable the plants to develop their bracts to perfection. In spite of the abundance of *Chrysanthemum* and other flowers at this time of year, *Poinsettias* are indispensable where much furnishing has to be done, as well as for the decoration of the stove or intermediate house. When required for cutting, the bracts, with a sufficient length of stem, should be cut and steeped in water overnight.

Propagating stove plants.—Where fine-foliaged plants in a small state are in frequent request for the decoration of the dinner-table and sundry other purposes, it is necessary to propagate fresh stock every few months because the plants in time become too large for what they are required. In a well-heated propagating-case cuttings of such things as *Crotons*, *Dracenas*, *Pandanus*, etc., root quickly, and if grown on freely afterwards soon become of a serviceable size. A good batch of cuttings of subjects found to be most useful may now be inserted, each one singly, in small 60-sized pots and plunged to the rims in the case. Little or no shading is required at this time of year; but the case should be opened each morning to freshen the internal atmosphere and for the purpose of wiping off the condensed moisture on the under-surface of the glass.

Grease-bands.—Where the placing of grease-bands round the stems of fruit-trees is found effective in the trapping of the females of the winter moth when ascending the trees for the purpose of egg-laying, the same should be fixed in position without further delay. Grease-proof paper only should be employed. This must be bound so tightly round the stems that it is impossible for any insect to pass between the bark and bands. For these traps to remain effective it is necessary to frequently renew the grease.

Chicory, when in request for salad-making, may now be taken in in relays to the Mushroom-house or any place where the temperature is suitable and from which light can be totally excluded. A mild warmth is sufficient, anything beyond this only leading to the growth becoming drawn and attenuated.

Globe Artichokes.—Although not as yet necessary to afford the stools protection, preparation for doing so in the way of driving in from four to six stakes round them to hold the litter in position when necessary to apply it should now be done. Fine cinder-ashes should also be placed round them to a height of 9 inches. This done, the litter can be quickly placed round them at short notice.

Broccoli.—A good deal of frost has been experienced of late, which has meant that where needful precautions were not taken to well cover developing heads with several layers of the outside leaves they have been rendered useless. Where ample shed accommodation exists, the difficulty can be surmounted by lifting with some soil attached to the roots all not required for present use, standing them close together in an open shed. Here they are quite safe without further protection, unless very severe weather should set in, when the whole may for the time being be covered with dry litter or Bracken. In this way the supply can be maintained with little trouble.

Turnips.—Fully-grown roots should now be pulled and stored, or, rather, clamped, as they keep much better so treated than if put into the root store. Several small-sized clamps are better than one or two larger ones, as there is then no danger of heating taking place. A sufficiency of soil must be placed over the covering material of long litter to prevent frost penetrating and damaging the roots.

Cropping.—A well considered scheme for the future cropping of the kitchen garden should now be drawn up and the various plots prepared accordingly. If the details are entered in a note-book and kept handy for referring to as occasion arises it saves much time and trouble later on. Manuring should be done in accordance with the scheme, using planks for expediting the wheeling in of the manure as well as to avoid the cutting up of paths and converting the surface of the soil into a hard, compact mass, when waiting for hard weather is out of the question. Whenever practicable, digging should be pushed on with, throwing the soil up as roughly as possible for wind and frost to exert their sweetening influence on the same. If possible, any plot in need of more than ordinary digging should be double-dug, or, as it is termed, bastard-trenched. This will afford an opportunity for getting rid of any rough kinds of manure or old hotbed material in a partly decomposed condition, as such can be worked in with the lower spit, thus saving that which is of a richer nature for mixing with the top spit.

Flower garden.—Before frost renders such work impracticable the hoe should be run through the surface of the flower beds, such stirring having become necessary as a result of the very heavy recent rains. While doing so, special attention should be paid to Wall-flowers, which are apt to become loosened by high winds, and require being trodden round to make them firm again. So long as the weather remains open the lifting and planting of trees and shrubs should be persevered with. A. W.

MIDLAND COUNTIES.

Early Peach-houses.—The trees having been pruned, cleaned, and trained as advised in previous notes, the house will now be closed for starting. Only sufficient fire heat will be necessary at present to prevent the temperature falling below 45 degs. The trees will be syringed freely with tepid water on fine days at about one p.m., closing the house at the same time. Should severe weather render the regular use of fire heat necessary, care must be taken to maintain a moist atmosphere by occasionally sprinkling the walls and paths with a rose-can. The house must be ventilated freely whenever the weather conditions are favourable, and endeavour to change the atmosphere every day. When the

Cleaning of Vines is completed remove the surface-soil of the border down to the roots and apply a fresh dressing of good fibrous loam, adding a 6-inch potful of Vine-border compound (fine grade) to each barrowload of soil. Test the border with a soil-tester, and if the soil is found to be dry give a thorough watering, which will last throughout the winter. Apply a good mulch of manure from a spent Mushroom bed or similar material, and the house will then be ready for starting. As opportunity affords the interiors of all fruit-houses should be thoroughly cleansed.

Broad Beans.—A small sowing of these has been made on ground that was previously trenched and manured. A site was chosen in

a sheltered part of the garden and where the soil is not too heavy, for, although the Broad Bean succeeds best in a somewhat heavy soil in summer, it is not advisable to sow in such a medium now. The seed is sown in rows 3 feet apart, and covered with 3 inches of soil, afterwards giving a light mulching of manure to protect the roots from frost. Some seeds were sown in a box at the same time and placed in a cold frame for providing plants for filling any gaps in the rows.

Autumn-sown Spinach is looking remarkably well. The soil between the rows is stirred with a Dutch hoe when the ground is sufficiently dry to enable the work being done. The plants of the latest sowing should not be thinned too severely, but overcrowding should be avoided.

Chicory.—The crowns may be lifted now and placed in the Mushroom-house, where it is perfectly dark. A temperature of 55 degs. is sufficient to force Chicory. A damp, stagnant atmosphere should be avoided or the young growths will soon decay. If a small quantity only is required, Chicory may be grown in pots, in the same manner as Seakale. Six good crowns will be sufficient for each 8-inch pot. Make the soil moderately firm, leaving about 1 inch of the crown uncovered. When growth commences an inverted pot of the same size should be placed over the crowns. If the soil is in a moist condition at the time of potting, little or no water will be necessary, but if the soil is dry, a good watering should be given as soon as the potting is finished.

Rhubarb.—If it is intended to make a new plantation of Rhubarb the ground should be heavily manured and trenched at the first opportunity. The site should be an open one, except that it needs protection on the north and north-west. When the trenching has been done, a good dressing of fresh soot and lime should be applied to the surface, and the ground left in this condition until February or March, when the Rhubarb should be planted. The best method of propagating Rhubarb is by dividing the stools as often as it becomes necessary. Owing to the scarcity of Apples, forced Rhubarb will be in more demand this season. In order to keep up a continuous supply, fresh batches of roots will be introduced to the Mushroom-house every three or four weeks.

Green crops.—The mild, damp weather during the early part of November has suited the late-planted green vegetables. We have obtained up to the present excellent salads from plants in skeleton frames, merely protected at night with mats, but there is a danger now from frost, and plenty of material, such as mats, straw litter, or Bracken should be at hand to protect the frames. Whenever the weather is favourable admit air freely to all crops in frames, and keep the plants clear of decaying leaves and rubbish, also stir the soil on the surface. F. W. GALLOP.

SCOTLAND.

Auriculas.—Where these fine flowers are extensively grown there is almost certain in such a season as this to be a proportion of losses during the winter from damp. Especially is this the case when the soil in which they are grown is naturally heavy and retentive. To a great extent this danger may be minimised by lifting the finer varieties and planting them temporarily in lighter and warmer soil, preferably at the foot of a south wall. In such a place they will winter in a very satisfactory way, and can be returned to their permanent places in spring. It is remarkable nowadays to notice how seldom the fine old yellow *Dusty Miller* is seen in collections of *Auriculas*. If a batch of plants be potted up now and placed in a cold-frame their period of blooming will be accelerated and the flowers will be clean and pure.

Cold-frames.—No one, I suppose, has ever too many cold-frames. These structures are useful in many ways, but at this period of the year they do not always receive the attention which the inmates require. Many of these frames stand on beds of ash, which are very retentive of moisture. Consequently, there is a danger that the plants in such may suffer from damp. At this time, therefore, let the sashes be removed on all favourable occasions;

and if heavy rains should occur, when, necessarily, the sashes must be replaced, let the tilts be kept at their utmost stretch. Protecting materials, too, must be in readiness against sudden spells of frost. Good Archangel mats are, perhaps, more reliable than anything else, but mats made of reeds have considerable value as well, although these are not so durable.

Fruit-trees under glass.—Now that the foliage has in most cases dropped, a beginning can be made with cleaning the trees. Even although these may have been free from pests during the season this work ought not to be omitted, for it is just by these annual cleanings that vermin is prevented from obtaining a lodgment. Where the trees are known with certainty to be free from pests, a wash over with fairly strong soapy water in a tepid state will suffice. Either soft-soap or Sunlight soap is recommended. The heavier wood may be treated with a fairly stiff scrubber; but the shoots must be washed with a soft brush. Where pests may be present an addition to the soap and water may be made in the shape of Gishurst compound—a reliable article if now of some antiquity. In the case of Figs, let any small fruits be removed. These will not now mature, and are much better dispensed with. Any necessary top-dressings or the substitution of fresh for exhausted material will, of course, be attended to at the same time.

Hardy fruit-trees.—In spite of the advanced season, the foliage is not yet disposed to ripen. Especially is this the case among stone fruit—Plums, Peaches, and Nectarines. There is yet, unfortunately, in the case of the two latter varieties some appearance of growth in the current season's shoots, and in the absence of frost this growth may yet be maintained for a time. Pear-trees and Apple-trees, too, are more or less green in leaf, although some of the Pears are assuming autumn tints.

Raspberry plantations.—Owing to pressure of work, combined with incessant rains, it has not hitherto been found possible to cut out the exhausted canes. During the week, however, a good beginning has been made with this work. The exhausted canes are at once taken to the fire-heap, and at the same time a tentative thinning is done among the current season's growths in the stools. The final thinning will not be done until training takes place; and, as the foliage yet hangs, this will be delayed for a time. It may be said that in thinning Raspberry canes those to be removed are pulled up by the roots. This is a much more satisfactory way of dealing with these canes than cutting them over with knife or hoe, for the roots left will push forth other, if weaker, suckers from dormant eyes, which, in turn, will require to be removed. After training, a very light forking will be given, and a good mulch of well-rotted manure will be spread over the quarter. This is a good time at which to make new plantations. Bearing in mind that the canes will occupy the quarter for some years, let the break be liberally dealt with, and the planting carefully done. It is almost superfluous to say that no crop need be expected from a new plantation the first season. The canes, in order to lay the foundation of future success, must be cut down to four eyes from the bottom.

Planting.—If it is proposed to undertake any planting at the present time, let the stations be prepared in advance. It is a sound rule never to delay planting after trees or shrubs are received—provided always that the weather is suitable. In the event of heavy rains, or of frosts, do not unpack, but put the bale as it is into a cool and airy place. Nursery packers are so expert that the delay of a few days will do no appreciable harm.

Bulbs.—Those who are so fortunate as to have a batch or two of Roman Hyacinths will find that these will now bloom without anything very special in the way of heat; and, indeed, I always think that the earliest lot is the best, and lasts in an effective state over a longer period than those which are subjected to a higher temperature. Similar observations apply in the case of Paper-white Narcissi or of the yellow variety of that family. Too much heat draws the flower-stem and makes the bloom weak and spindly. For blooming at

Christmas, a batch of Duc van Thol Tulip is valuable. These can be safely given a pretty high temperature, but from the time of their introduction to the stove or forcing-house they must be liberally supplied with moisture. If the pots or bowls in which Tulips are grown can be placed upon a shelf near the glass it will be of advantage. An eye must be kept from time to time on further batches in the plunging bed. W. McGUIFFOG.

Balmæ Gardens, Kirkcudbright.

ROYAL HORTICULTURAL SOCIETY.

NOVEMBER 21ST, 1916.

If not of great extent, the fortnightly meeting held on this date was not without interest, the excellent groups of Chrysanthemums being chiefly responsible for the display. What is undoubtedly apparent at these late-autumn meetings is the growing interest in Nerines, their brightness at this dull season of the year, added to simple cultural needs, making them popular. The modern-raised hybrids, too, embrace a wider colour-range with many pleasing shades. Carnations and winter-flowering Begonias were on view, though the fine exhibits of the latter which for years from Messrs. Veitch were a brilliant feature of these autumn meetings now no longer find place. Choice Orchids were freely shown. An exhibit of Savoys, the pick of a recent trial representing this useful vegetable, was sent from Wisley. Several novelties received recognition.

HARDY PLANTS.

The best of these at this meeting were the hardy evergreen Ferns, Polypodiums, Polystichums, and Scolopendriums from Messrs. H. B. May and Sons, and if valued in summer for their cool-looking, refreshing greenery, are equally welcome in their maturer garb to-day, whether in cold-house or fernery in sequestered nook in the open. The finer Hart's-tongues are those of the crispum set, that known as maximum being one of the best shown. *S. crispum Robinsoni* is another good and distinct sort, while multiceps and grandiceps of the crested group are indispensable. Of the Polypodies, *P. trichomanoides* (most elegant), *P. cornubiense*, *P. Barrowi*, and *P. Prestonii* (all forms of *P. vulgare*, the last two varieties of *P. v. cambricum*) were the best. *Lastrea pseudo-mas crispa cristata angustata* is a distinct and pretty evergreen form heavily burdened with names and of especial value in the smaller fernery. Many Polystichums were shown, and, among other things, the rare *Ceterach aureum*, which is seldom seen. Charming pots of autumn-flowering Crocuses were among the best things from Mr. G. Reuthe, the pure and handsome *C. marathonisius*, *C. longiflorus*, and *C. Tournefortii* being in good form. Flowering sprays of *Lapageria rubra* cut from Keston woodland, the oncoming buds bleached by the recent snow resting on them, showing this fine climber to be hardier than many suppose.

SHRUBS.

Sprays of cut Conifers in about a hundred sorts were staged by Messrs. J. Cheal and Sons, and while far less educational as to habit and other things than growing plants—an almost impossible thing in these days on any large scale—were useful by way of comparison, and seasonable to boot. Among the more interesting were the Macedonia Pine (*Pinus Penke*), the Serbian Spruce (*Picea omorica*), *Tsuga diversifolia* (very neat-habited), *Juniperus arizonica*, *Cupressus arizonica*, and *Abies balsamica Hudsonica* (the last a slow, dwarf-growing plant of considerable beauty and of value in the rock garden). *Abies excelsa Remonti*, also noted, has a like value.

NERINES.

These are of growing importance, the three collections of modern hybrids staged demonstrating a wider interest than we remember. Messrs. Barr and Sons had many of exceeding beauty in the cut state, Coral Queen, Vivid, Nigel (rich carmine and crimson), Sylvia (white and rose), Leonora (of a pleasing deep salmon shade), and flexnosa major (pink and white). In the group from Messrs. Herbert Chapman, Limited, were several choice things, the majority being under number. The most brilliant was "I C." (*Planti x Lady Dorington*), of intense rich rose. *N. flexnosa alba* and a hybrid apparently identical with Messrs. Barr's *N. flexnosa major* were others of note. The largest collection was that from Mr. G. Renthe, who, in addition to a fine group of *N. coruscans major* and *N. flexnosa alba* (scarlet and white respectively), had a fine series of hybrids in pots. Those of rose and salmon shades were particularly attractive, and of these, *Kestonia* (salmon and rose), Quakeress (pale salmon), Dream (rosy-salmon), and Mrs. Reuthe (clear salmon) were remarked. The hardy *N. Bowdeni* and the pretty, free-flowering, white and pink *N. pudica* were among others.

GREENHOUSE PLANTS.

Prominent here were the well-grown winter-flowering Begonias from Lord Brownlow, Ashridge Park, Berkhamstead (gardener, Mr. D. Robertson). *F. H. Cook* (clear salmon), *Apricot* (a pale, yet beautiful, shade), *Scarlet Beauty*, and *Sunrise* (brilliant scarlet) were among the showiest. Some good *Gloire de Lorraine* were in the same group. Very refreshing, too, was it to see again well-flowered examples of the Mexican *Sericographis Ghiesbreghtiana*, now included under *Jacobinia*, whose abundance of crimson-scarlet flowers and elegant habit rendered it an indispensable winter-flowering subject many years ago. Messrs. R. F. Felton and Sons had a most attractive exhibit of *Hakea laurina*, the plant referred to previously as *H. eucalyptoides*. On this last occasion the ball-like inflorescences of crimson and sulphur were larger and more strikingly brilliant than before. *Eucalypti*, in flower, of different kinds were also on view. *Begonia Emita* and a variety of Carnations were shown by Messrs. Stuart Low and Co. Of Carnations, Messrs. Allwood Brothers had an excellent exhibit. *Wivelsfield White* and *Benora* (fancy) have rarely been finer, while *Enchantress Supreme*, *Mary Allwood*, *Nora West* (a charming salmon-pink), and *May Day* were notably good. The new variety *Nancy* has decidedly improved since being housed, and now presents a refined beauty not earlier remarked. It is one of the prettiest of soft-pink shades. *Rose Sensation* (a sport from *Pink Sensation*) gained an Award of Merit. It came from Messrs. W. Wells, Limited.

CHRYSANTHEMUMS.

Two superb tables of these helped the show considerably, their variety as much as their excellent quality constituting a great attraction. In that from Messrs. W. Wells, Limited, two novelties appeared, both gaining awards. They are *J. Bryant* (exhibition Japanese), of giant form and purest white (it will doubtless please the exhibitor), and *Lady Stanley* (decorative), crisp of petal and of a delightful silvery pink. This in our opinion is far more likely to fascinate the millions, who prefer medium-sized flowers of refined beauty for the decoration of the home. A third variety, also gaining an award, was the single-flowered yellow *Mrs. Moss*.

It is of rich butter-yellow tone, Mr. Phillip Ladds being the exhibitor, though it found place in Messrs. Wells' group. Messrs. H. J. Jones, Limited, had many handsome stands of flowers, the back row being entirely of big exhibition sorts. Mrs. C. Edwards (very handsome white), Mrs. H. Kemp (golden-bronze), and Mrs. R. C. Pulling (rich yellow) were the finest of these. Audrey (brunzy yellow), Gerlie Ladds (crimson), Excelsior (bronze), and Jessica (reddish-crimson) were the pick of the single-flowered sorts.

ORCHIDS.

Two of the three novelties receiving awards were from Messrs. Armstrong and Brown. They were *Cattleya Cläsiana* alba Orchidhurst variety (*C. intermedia* alba x *C. Harrisoni* alba) (by far the best white *Cläsiana* yet seen) and *C. Monastir* (*C. Freya* variety Mrs. Fred Sassoon x *C. aurea*) (a brilliant form having overlapping wine-red sepals and ruby-crimson lip with golden lines. In the group, this firm had many fine blotched *Odontoglossums* bearing only a solitary flower, while *O. Harryanum crispum* carried a superb raceme. A central group consisted of *Cattleya labiata* alba and *C. Cläsiana* alba (both very chaste and beautiful). Messrs. J. Cypher and Sons had an exhibit wholly of *Cypripediums*, a group in which they have specialised for many years. *Lecanum magnificum*, *Gaston Bulteel*, and *Sir Redvers Buller* were of conspicuous merit. The handsome new *Cypripedium* *Mme. Albert Fevrier* (*Germaine Opoix* x *Harefield Hall*), from Mr. G. F. Moore, *Bourton-on-the-Water*, was also in charge of Messrs. Cypher. The roundly-formed dorsal sepal is copiously spotted crimson and chocolate. Messrs. Sander and Sons contributed *Cattleyas* in variety, *Brasso-Cattleya Thornton* and *B. C. Thompsoni* being the best things from Messrs. Charlesworth, and *Cattleya Brenda* (pure white) and *Brasso-Cattleya Apollo*, two choice items in a group from Messrs. J. and A. McBean.

VEGETABLES.

Seven varieties of Savoy—those receiving recognition in the recent trial at Wisley—were on view. Perfection, a compact grower, of medium size, well hearted, from Messrs. Sutton and Sons (Award of Merit); Sugar Loaf, of conical build, also from Messrs. Sutton; and Norwegian, recommended for hardiness, from Messrs. Barr and Sons, each received three marks (x x x). Tom Thumb (re-selected), Messrs. Carter and Co.; Drumhead Covent Garden Late, Watkins and Simpson; Selected Drumhead, Messrs. Sutton; and Perfection, Hurst and Son, were given two marks (x x) each. Seeds of forty-seven different stocks were received and subjected to trial, the above-named being adjudged the most worthy.

A complete list of the certificated plants and medals awarded will be found in our advertisement columns.

Horticulture after the war.—The president and council of the Royal Horticultural Society have summoned a meeting at the Royal Horticultural Hall, Vincent-square, Westminster, at 4 p.m., on December 5th, at which it is hoped that all those interested in commercial horticulture will be present. The object of the meeting is "to consider the interests of the horticultural trade and the best means of safeguarding its interests after the war," and to pass a resolution. The chair will be taken by Lieut.-Col. the Rt. Hon. Mark Lockwood, M.P., C.V.O. In view of the urgent importance of the subject it is hoped that the meeting will be as representative as possible of all branches of the horticultural trade.—W. WILKS, *Secretary*.

CORRESPONDENCE.

Questions.—*Queries and answers are inserted in GARDENING free of charge if correspondents follow these rules: All communications should be clearly written on one side of the paper only, and addressed to the EDITOR of GARDENING, 63, Lincoln's Inn Fields, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent each should be on a separate piece of paper, the name and address being added to each. As GARDENING has to be sent to press some days in advance of date, queries cannot always be replied to in the issue immediately following their receipt. We do not reply to queries by post.*

Naming plants.—*All who wish their plants to be rightly named should send fair examples of each—the stem, leaf, flower, or fruit. (Snippets of leaves and points of shoots are useless.) Not more than four plants should be sent in any one week by the same correspondent. Where more than one kind is sent they should be numbered. Of course the fruit should always be sent.*

Naming fruit.—*Several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruits for naming, these in many cases being unripe and otherwise poor. We can undertake to name only four varieties at a time.*

PLANTS AND FLOWERS.

Rust on Chrysanthemums (Rez).—Your *Chrysanthemums* have been attacked by rust. The following has been recommended as a remedy: Dissolve 1 lb. of bluestone (copper sulphate) in 10 gallons of water; boil 1 lb. of lime and 1 lb. of treacle in 1 quart of water for half an hour. When this is cold pour it into the 10 gallons containing the bluestone. Then syringe the plants with this. Should the rust have spread in the meantime—and it does so very rapidly—a remedy has yet to be found that will do good in bad cases. The best way will be to destroy all the affected plants and start with a clean stock next year. Do not on any account attempt to increase your stock from the affected plants.

Heaths after flowering (M. T.).—After flowering, cut the plants into shape, shortening back the long, vigorous shoots to one-third their length, then place them in the greenhouse to encourage fresh growth. When the young shoots have made about half an inch of growth, repot, using sandy peat, and see that the drainage is free. Pot firmly, stand the plants in a frame kept close till they have recovered from the check, then stand them in the open, plunging in ashes to save watering. Water very carefully, taking care this is not overdone, as if this happens the soil gets soured and water-logged, which will be fatal. Guard against dryness at the roots as well. When the cold nights come, remove to the greenhouse, ventilating freely on every favourable occasion.

TREES AND SHRUBS.

Climbers for north wall (Grace Guinness).—Any of the hybrids or species of *Clematis* will grow and flower, but less well than in a westerly position. *Vitis inconstans* will also succeed, also *Clematis montana*, *C. Vitiella* in its many forms, *Crataegus Pyracantha*, *Jasminum nudiflorum*, *Lupinus arboreus*, *Euonymus radicans variegatus*, and the many forms of *Ivy* we now have. The position is not at all suited for flowering climbers and flowering shrubs, as the wood never gets properly ripened. Of *Roses* to give a succession of bloom, there are none better than a selection of the many Hybrid *Teas* now to be had, choosing for the wall those climbing varieties that have *Tea* blood in them. Any *Rose-grower* should be able to supply the *Rose* you want.

FRUIT.

Making a Peach border (H.).—A border for *Peaches* under glass should be made of good, sound, turfy loam, with plenty of old mortar rubbish, and some ½-inch bones, say about

2 feet deep of soil, resting on good artificial drainage, if in a wet locality; if in a dry one, then but little or no artificial drainage is required. The border may be made about 6 feet wide at first, and be afterwards added to as required. Now is a good time to get in the materials and make it, and the trees can be planted at the earliest opportunity.

VEGETABLES.

Saving Tomato seeds (George Duthie).—The simple method to adopt in saving seed of *Tomatoes* is to select one or more of the handsomest fruits when quite ripe, and to cut them in half, not from the stem downwards, but crosswise. Then with the blade of a pen-knife draw the seeds out from the pockets into a small basin. The flesh of the fruits can then be used cooked or otherwise. Wash the seeds well, strain them, and lay them out to dry on paper. Keep them moved a little to prevent sticking to the paper till quite dry. Then put into a small box or paper packet and keep dry till you want to sow. We know of no book that deals with the growing of plants for seed. The chief point in growing plants for seed is to see that there are no rogues among them—i.e., plants which are not true to the type. If you find any one plant which seems an improvement on the type, then such an one should be marked, and the seed saved from same, and grown on to find out whether the plant selected retains its distinctness.

SHORT REPLIES.

Applicant.—You will find an article dealing fully with basic slag and its uses in our issue of August 8th, 1914. A copy of this can be had from the publisher, post free, for 1d.—**R. F. Godfre.**—The native country of all the *Irises* you inquire about is given in the "Kew Hand List of Herbaceous Plants," second edition.—**A Regular Reader.**—The gas-lime you send is of very little, if any, value for the destruction of pests in your vegetable garden. This, to be of any value, should be used fresh and forked into the ground, which should not be cropped for, at the very least, three months after it has been applied.

NAMES OF PLANTS AND FRUITS.

Names of plants.—**F. S.**—The *Spindle-tree* (*Euonymus europæus*); 2, *Escallonia macrantha*.—**C.**—1, *Schizostylis coccinea*; 2, The *White Beam* (*Pyrus Aria*); 3, *Cotoneaster microphylla*; 4, *Berberis Aquifolium*.—**Miss K. Kenilworth.**—Judging from the poor specimens you send, we should say that the specimens represent *Rosa Wichuriana*, the type.—**K. M.**—Self-heal (*Prunella vulgaris*).

Names of fruits.—**Murray T. Foster.**—Apples: 1, *Isle of Wight Pippin*; 2, *Seigende Reinette*; 3, *Schoolmaster*; 4, *King of the Pippins*.—**J. S. Crossfield.**—A *Greave's Pippin*, cooking variety, should not be gathered till end of October, in use January to March; **B. Dr. Harvey**, cooking, gather early in October, in use from November till end of year; **C. Lewis's Incomparable**, useful either for dessert or cooking, its season of use is from January to March, gather end of October; **D. Bringewood Pippin**, dessert, gather end of October, in use from January to March.—**M. S.**—Apples: 1, *Winter Hawthornden*, 2, *French Crab*; 3, *Norfolk Beanfin*. *Pear*: *Belle Julie*.—**R. W. M.**—Apples: 1, *Lady Henniker*; 2, *Lord Burghley*. *Pears*: 3, *Glou Morcean*; 4, *Nonvelle Fulvie*.—**A. White.**—*Baumann's Red Winter Reinette*.

NOTES OF THE WEEK.

Erigeron strigosus.—This charming and Daisy-like flower, from N. America, keeps on after all the Michaelmas Daisies are past. It is now pretty, with its pale lavender flowers and silvery buds, and comes in well as a cut flower for the house, where I have it on November 24th.—M. G.

Escallonia organensis.—Messrs. Pennick and Co. send us from their nursery at Delgany, Co. Wicklow, some sprays of this very interesting species. It is not hardy except in Cornwall, but deserves the shelter of a wall on account of its beautiful rosy-red flowers. It is a very old plant, having been discovered in the Organ Mountains in 1841 and introduced to England some years later by W. Lobb.

The new forms of the alpine Forest Heath (Erica carnea).—Will any of your readers who have had success with these kindly tell us? My lot is not very happy-looking, not having got into the right soil, but two or three kinds in flower the last week in November promise well when effectively grouped. In the case of these new forms, too many kinds were sent out. Three of the best would have been a better start.—W.

Saponaria ocyroides.—There is still quite a number of flowers on a patch of this growing in a retaining wall, though it is the middle of November. They are only scattered over the plant, and are in nothing like the profusion which is displayed in the spring when the whole patch is literally covered with the pretty little rose-pink flowers. I know of no more profuse-blooming alpine than this, nor any more charming, and it is one of the easiest to grow.—W. O.

Erica carnea.—My plants are as full of buds as they can be this year. This species does very well in my London garden, and thrives in a compost of sandy leaf-mould. The chief drawback to it is that, flowering in the winter, the blossoms very quickly get dirty from the smoke and fog, and lose their beauty. The white variety grows well, but, so far, has not flowered so freely with me as the type. This species is said not to mind a little lime in the soil, but I think it does best without.—N. L.

Gentiana verna.—I have been much interested in the correspondence on *Gentiana verna* in your columns. With me the plant thrives and blooms freely, and always has a second flowering season. It is growing on a sunny, raised part of the bog garden in a mixture of peat, sand, loam, leaf-mould, and lime,

with its roots in rotted Grass turves. I attribute my success largely to the heavy top-dressing given to it, the crowns being kept always just above the soil, instead of at the end of long straggling growths. I also give it the protection of glass during the winter.—E. D. P., *Strawberry Hill, Middlesex.*

Cheiranthus linifolius (p. 575).—Mr. Buxton will flower this *Cheiranthus* freely if he will treat it as a biennial and not as an annual. In 1915 I filled two beds with this Wallflower exactly as described by Mr. Buxton and with identical results. In the autumn, as an experiment, I lifted the best plants and heeled them in against a west fence. Last spring these plants were removed to vacant places in the rock garden, where they have flowered splendidly, quite a fair sprinkling of blossoms still being visible in the middle of November. I shall let these plants remain another season, for some of them look sound enough to prove perennial.—C. TURNER, *Highgate, N.*

Lilium regale.—"E. H. Jenkins," in writing of this Lily, on page 596, states it gained "an Award of Merit in 1912, though probably no Lily has more richly merited first-class honours." The fact has apparently slipped his memory that it was given a first-class certificate at the Holland Park Show of 1915. When the Award of Merit was bestowed at the International Horticultural Exhibition of 1912 it bore the specific name of *myriophyllum*, but at Holland Park in 1915, when a first-class certificate was awarded it, this Lily was shown by Miss Willmott as *Lilium regale*. It is certainly a Lily for which a great future may be anticipated in British gardens.—K. R. W.

Trees damaged by horses.—Trees are often damaged by horses and other farm stock gnawing the bark and wood, this resulting in decay if not promptly attended to. Painting with tar or creosote is generally resorted to, but in many cases without success. By mixing a teaspoonful of tincture of *asafoetida* in half a bucketful of liquid clay and applying thickly to the damaged parts the gnawing will usually cease. The cheapest and most satisfactory way is to surround the stem with a guard of wood or iron. A neat and efficient tree guard is made as follows:—Procure a number of Larch or Chestnut poles up to, say, 7 feet in length and about 2 inches in diameter at top end. Thread these on stout fencing wire by boring holes of a suitable size in the poles at about 2 feet from top and bottom, keeping each couple separate by 3-inch lengths of the same poles

threaded lengthwise on the wire. This can best be arranged on the ground, and when a sufficient number to surround the stem has been wired together, the whole may be lifted up and placed in position around the trunk. Another method is to bind the poles together with two strands of fencing wire, at a short distance from top and bottom, giving the wires a double or treble twist between each pair, so that the poles may be kept at stated distances apart.—A. D. W.

Trees in Bunhill Fields Cemetery.—The treatment of the Poplar and other trees in this cemetery leaves much to be desired, especially as the place is associated with such names as John Bunyan, Daniel Defoe, and Isaac Watts. On entering from Bunhill Row one is faced on the left by two dead or dying stumps of Poplar, and on the right by broken-topped specimens of the same tree. Further along, several of the decrepit Planes and Poplars should either be removed altogether, or the overhanging branches of the adjoining trees carefully pruned back. In other cases removal of the dead wood would greatly improve matters. Altogether the place has a neglected appearance, which might be greatly improved by attention to existing trees and the planting of a few other suitable species.—A. D. W.

[This is true also of some of the London West End parks, where broken-backed Elms are too common.—Ed.]

Box edgings in kitchen gardens.—I am surprised to see that anyone calling himself a gardener should write as "K. P." does in GARDENING ILLUSTRATED.

Box forms a very suitable edging to kitchen garden paths, and nothing has a nicer appearance when it is kept dwarf and regularly clipped.

A waste of labour in hard times, and at all times, for mice, vermin, and other enemies it forms a fine cover, and they know it. The right edging for kitchen gardens is one that gives no shelter or shade to mouse, rat, or slug, and one that does not rob the ground as Box does. I can see some pretence of reason in the Box edging being used in a flower garden to carry out some silly idea of an old-time garden, but in a kitchen garden it is ridiculous. I would rather have no edging at all, as in the Paris market garden.—W.

Berberis Darwini.—Beautiful though this evergreen is as a bush in the shrubbery or on Grass, it is more so when grown as a hedge. In some years severe frost may cripple the top portion of the plants, but they quickly recover. Thirty years ago I planted a hedge of it on each side of a

Grass path, with a narrow flower border on each side, and it has been a great success. Some twenty-five years ago severe frost crippled some of the plants, but they recovered. I planted, as a protection, one common Holly to two Berberis, which grew together nicely, making a neat and thick hedge, now 6 feet high. The annual cutting is done in June, after flowering is past. A strong after-growth is then made which blossoms freely the following spring.—S. P.

Rose Zephirin (page 499).—I quite agree with "R. H. S." as to the merits of this Rose. It is a charming variety and has many good points. I find it a consistent bloomer and still in flower at the time of writing (November 21st), in spite of the extremely bad weather of the last week, when most of the others, Caroline Testout excepted, were completely shrivelled up. My soil is a fairly stiff loam, and Roses generally do well with me. I cannot agree with the remarks of "R. H. S." about the name of this Rose; one might as well call Prince de Bulgarie simply "Prince," which would convey nothing to the reader; further, it would be impossible to call all Roses, or, for the matter of that, any other plants, by names of a single word.—G. H. S. R., *The Bury Manor, Wick, Nr. Bristol.*

[We hate *rigmarole*, and disagree as to this. Long and compound names to Roses are too common and very ugly. We are not going to use any but the single name for this.—ED.]

Cotoneaster frigida.—This comparatively little-known species will presently prove one of the most popular—and deservedly so—of its tribe. A vigorous grower, summer-leaving in character, developing when grown as a standard into a low-spreading tree, its ornamental aspect can hardly be over-estimated. In bush form its more lax habit of growth does not, so far as my experience goes, display it to equal advantage. I have seen it thus without being greatly impressed. Standard-grown, as I saw it in October in a garden on the east coast, it was very beautiful, the nearly horizontally-disposed branches laden with big clusters of scarlet fruits. No member of the genus known to me is similarly endowed either in habit or fruit effect, and those who would get an idea of its value should so group it on the lawn or elsewhere, or even plant it by itself, in order that its better side may be revealed. For the season named few things can compare with it, and, so far as I know, none surpass it.—E. H. JENKINS.

Berberis Sargentiana.—This is a Chinese species, and one of two Berberis each of which received a first-class certificate from the Royal Horticultural Society on November 7th last, a rather unusual circumstance. *B. Sargentiana* was given an Award of Merit in August, 1915, its higher merit being recognised in the new award. An evergreen kind, and, without doubt, the most ornamental of its class, having a leaf character approximating to *B. Wallichiana*, it is of striking beauty in autumn, when the handsome leafage assumes a mingling of green, bronze, and scarlet, which remains effective for a long season. Bush-habited, its good attributes will be seen to best advantage probably when the plant is grown as an isolated example in open positions. Apart from leaf-beauty and other characteristics marking it as a plant of distinction and merit, the long, rigid, ivory-white spines with which the younger branches are armed are also a feature. The fruits are small, dark in colour, and of no great ornament. This species was exhibited by Mr. E. Beckett, gardener to Hon. Vicary Gibbs, Elstree, Herts.—E. H. J.

FRUIT.

GROWING PEARS.

To secure Pears free from scars and with a full, luscious flavour when ripe, not only must the roots be in a healthy and satisfactory state, but the soil also must be in a high state of fertility. Very often after a time the soil, as it were, becomes exhausted—that is, if means have not been taken to keep it in a high state of fertility. No other fruit varies so much on diverse soils as the Pear, but the best qualities of any varieties are more developed on a warm and well-drained soil. It therefore rests with the cultivator to follow the methods of culture to secure the best results which the soil and district will allow. What are termed root-feeders or fibres must be present in sufficient numbers and be also within fair reach of the surface, so as to be able to supply in a quick and direct manner the requisite food. Very often the root-action is most defective, the result of their either being too deep down, having been brought to this stage by too much surface digging, or from want of nourishment.

Pears grown as cordons are often supposed to be short-lived, but they are not if surface feeding is systematically carried out. A few years back I had charge of a lot of cordon Pears, and the practice I carried out with these was to lightly prick over the surface in the autumn, and then with a rake to carefully pull back the loose surface-soil. In its place was given a surface-dressing of loam, rotten farm-yard-manure, and burnt garden refuse. The regular crops of fully-developed fruit annually produced testified to the value of these dressings. In the case of trees growing on light or gravelly soils, also whether growing in the open or against walls, the best course would be to prick over the surface, removing the soil down to the roots, and in its place to give a good dressing of the material mentioned above, but with this difference, that fully one-half should be rotten manure with a good addition of burnt refuse.

Trees on the Pear stock growing against walls are often seen in a barren state. To bring these into a state of fertility nothing short of root-lifting will suffice. In the case of large trees it would be highly dangerous to re-lift them wholly at one time; consequently, this operation should take place at two different times, viz., one-half of the tree one season and the other half the following. This, however, must be done carefully, or much mischief will ensue. A.

MANURING HARDY FRUITS.

This does not always receive the attention it should. A timely application of manure in the way of a surface mulch or otherwise to just bury the manure beneath the surface goes a long way towards maintaining fruit-trees in good bearing condition, especially varieties which crop regularly. These remarks apply equally as much to wall-trained trees as to those grown in the open garden or orchard, only in the case of Peaches, Nectarines, Apricots, and dessert Cherries the manuring may be deferred until after the pruning and training are finished. For Plums, Pears, Morello and Kentish Red Cherries it cannot be applied too early in the winter, and, if possible, should be lightly forked in. In these instances it is only the alleys which can be so treated, but in the open garden and orchard the manure can be spread to as far as the branches of each tree extend. As a rule, the soil beneath garden trees can be removed more quickly with a hoe than a spade, as it is more or less loose

for a few inches in depth. It is always best to bury the manure, if only just beneath the surface, as birds are then prevented from scratching it about and creating an untidy condition of the borders. All kinds of bush fruits need an annual dressing of manure, which, in regard to Raspberries, should be spread and left for winter rains to do the rest, for it is ruinous to the roots to dig the ground between the rows. A. W.

PRUNING APPLES AND PEARS.

No hard-and-fast rules can be laid down as to how the pruning of the different varieties should be done, for the work requires extensive knowledge. Young trees require rather severe pruning for the first few years to form well-shaped specimens, but it must always be remembered that certain varieties of Apples and Pears form their flower-buds at the ends of the shoots. Amongst Apples of this type may be mentioned Irish Peach, Mr. Gladstone, Jacob's Seedling, and Bismarck, and in the case of Pears, Beurré Superfin, Jargonelle, and Marie Louise. These must be treated accordingly. Shoots that fruited last year may be removed. If pinching the shoots in summer has been practised, young trees will require little pruning beyond shortening the leading shoots to 12 inches or 18 inches, according to the variety, and cutting back the side shoots to two or three buds. The young shoots of old trees that have filled their allotted space should be cut back to from two to four buds, according to the variety. It is generally safe to prune strong-growing varieties to four buds, and weakly or medium growing varieties to two buds. Old trees are often crowded with branches and fruit spurs, and, in consequence, sun-light and air are excluded from the inside branches, so that fruit is produced only on the outside of the trees. Some of the spurs and a few of the useless branches should be removed annually. Standard trees require very little pruning, but this should be most carefully done until the tree is five or six years old. The leading shoots should be shortened to about half their length and any branches which cross each other must be cut back. When pruning is finished gather up the prunings and other rubbish and burn them, and lightly prick up the surface of the soil with a fork. G.

NOTES AND REPLIES.

American blight.—Please tell me how to deal with fruit-trees coming in, which may be, I fear, infested with American blight?—S.

[You should get some methylated spirit, also a camel-hair brush. Dip the brush into a small bottle of the spirit and carefully soak each colony of the American blight with it. This, if persevered with, will clear off every one. In the old Chiswick days we adopted this plan with the mealy bug on the Vines, and found it was also efficacious in the destruction of American blight, which was prevalent on some of the cordon Apple-trees. It would also be well to syringe the trees with the caustic alkali solution after they have been planted. An eye should be kept during the coming spring on the trees that come to hand, and if any signs of the pest are visible apply the methylated spirit.]

Pruning standard and bush Apple-trees.—Would you kindly tell me the best way to prune standard Apple-trees which now have been planted two years? They were put in in December, 1914, not pruned in the spring, but in the autumn (December) of 1915. The long shoots—strong and 4 feet long—were cut down from 12 inches to 15 inches. They have now shoots 4 feet long, and I thought, as they have eight to nine shoots on each tree, I would only take 4 inches to 6 inches off the top

of these shoots. I had to summer-prune them as they made a lot of shoots inside. Is this the best treatment? Bush trees have made the same long shoots (4 feet). They were planted same time (December, 1914) and pruned December, 1915. I have got them into a nice shape, and now there are only the leading shoots (4 feet) to prune and a few summer-pruned inner shoots to cut back (some had good fruits on this year). How far should I cut these long shoots back? I understand a little of pruning, as I have done these from the beginning, but would like the best advice as to how to continue. Should I leave a third on—that is, cut two thirds off, leaving about 18 inches on? They are thick, strong shoots?—FRUIT.

[You had better shorten the long shoots mentioned, more or less to about half their length and in such a way that symmetrical-shaped heads result. Cut to buds looking outwards, and if any of the shoots are inclined to cross one another or are likely to encroach on each other do not hesitate to thin them. Each shoot should stand quite clear and some distance apart from its neighbour. You did quite right in summer-pruning the young side or lateral shoots. Cut these back now to three or four buds to form the bases of spurs for future fruiting. The bush trees should be dealt with in precisely the same manner, and if any of the shoots or future branches are at all likely to become crowded after the lapse of a few seasons train them in an outward direction now that they are young and supple. This is easily accomplished if the requisite number of short stakes is first driven in where required round the trees. Then, by attaching suitable lengths of tar-twine to the shoots needing attention, they can be drawn outwards to the desired positions and made secure by fastening the twine to the stakes. In the course of two or three seasons the branches become set, when the stakes may be dispensed with.]

The fruit-room. — In the fruit-room it will be necessary to overhaul the fruit, frequently removing all that show the slightest signs of decay. It is during the first weeks after storing that such fruits are found, for, in spite of every care, some blemished fruits are sure to find their way to the benches. As early sorts of Apples are cleared off, the later ones may be given more room. It is advisable to do this as soon as possible while the fruits are still hard and green, then there is little chance of bruising them. A mixed fruit-room is an evil, and a very common one, for the conditions which suit Apples best are bad for ripening Pears, and it ought to be the rule to have at least a small portion of the store-room divided off and kept warmer and drier for the benefit of ripening Pears, as these are much better when ripened in a temperature that would be too warm for Apples to be kept in. Pears should be tested day by day, as many sorts are liable to go sleepy almost as soon as they ripen, and in the early stages of this defect it is almost impossible to detect it from outside appearance.

Melons grown in cold frames. — The Melon is commonly considered delicate, needing a good deal of warmth and careful treatment. The summer and autumn of 1916 cannot be claimed to have been good for Melons in cool frames, yet in a neighbouring garden in a frame standing only on the natural soil of the garden some Melon plants of the British Queen type matured some uncommonly fine fruits, some even up to 7 lb. in weight, and what is so remarkable and unusual was the high flavour that was developed in this sunless, cool, and wet autumn. The frame accommodated Lettuces and other spring crops prior to the planting of these

Melons, the only addition being a little stimulating chemical manure. The grower had no confidence in the possible issue. The plants had been raised for other structures, and, the frame at the time being unoccupied, the Melons were planted on the remote chance of being at some time useful. There was quite a normal crop on each of the several plants, and their vigour was exceptional. This is a record that might inspire others to emulate, but the successful growth of Melons under cool conditions is such that one does not entertain the most hopeful results

Aloe ferox in bloom at Mount Henry, Dalkey, Co. Dublin.

by those even expert in Melon cultivation. On page 556 Cantaloup Melons are referred to by "W." as being similarly successful grown in cold frames without skilled attendance, a coincidence that seems to imply something in the peculiarity of the season favouring Melons thus treated. I have grown Cantaloup Melons in more favourable summers, but the flavour was poor, and for this reason have given them up. The shortness of labour has put a ban on Melon culture in many gardens this year, and the prospects of the future do not hold out any hope of their getting any better treatment. Economy is the rule, and I fear the Melon in many households will remain only a memory.—W. S.

PLANTS AND FLOWERS.

OUTDOOR PLANTS.

ALOE FEROX.

THIS, shown in accompanying engraving, is growing out-of-doors in Dalkey, Co. Dublin, Ireland, in a desert garden. It blooms regularly every summer. The plant when the photograph was taken was about 15 inches high and the flower-stem another foot. It is sheltered in the wet weather each winter by an overhead frame at night, but always open during the day. It is never protected in any way in spring, summer, or autumn. Being near the sea, south aspect, frost never troubles it in any way.

R. C. McM. SMYTH.

FRASER'S CRIMEAN SNOWDROP.

(*GALANTHUS PLICATUS FRASERI*).

THE Crimean Snowdrop is one of the most distinct of all the race, although in some respects less valuable in many places than the best forms of our common Snowdrop (*Galanthus nivalis*). Yet it is one which is of much value, its bold stature and fine leafage rendering it one which has appealed for long to lovers of the Snowdrop. It is of bolder habit than *Galanthus nivalis*, while the flowers of the best varieties are large and of great beauty, the pure white of the ground colour of the flower being intensified by the bold, saddle-shaped apical blotch, which is to be met with in almost all its varieties. The most characteristic feature of *G. plicatus*, however, is the leaf, which is broad and plicate, or folded back at the margin. It is a fine and distinct Snowdrop, which has been much employed by hybridisers and seedling-raisers. From various parents employed in hybridising, the late Mr. James Allen, of Shepton Mallet, the late Mr. William Thomson, of High Blantyre, N.B., and others have succeeded in raising some excellent Snowdrops.

Galanthus plicatus Fraseri is probably only a selected variety, its history being that Mr. W. B. Boyd, of Faldonside, Melrose, observed it growing among some Crimean Snowdrops in the garden of the late Mr. P. Neill Fraser, Edinburgh. It was taken care of, and distributed under the name of *G. plicatus Fraseri*, and has proved one of the finest of the Snowdrops.

As the popular name of Crimean Snowdrop would suggest, *G. plicatus* is a native of the Crimea, but it is also found in the Caucasus and adjacent regions. It appears to be one of the parents of *G. byzantinus*, although some consider that Snowdrop a species, but the latter is, on the whole, inferior to either of its parents, which are *plicatus* and *Elwesi*. The Crimean Snowdrop apparently thrives best in a good soil, but it seems peculiarly liable in some gardens to the attacks of the disease. It should be deeply planted, and I have at various times planted it at from 6 inches to 12 inches deep with advantage.

S. ARNOTT.

Yucca Whipplei.—The note by "J. Harry Johnson," on page 575, gives interesting information regarding different forms of *Yucca Whipplei* in South California. It would be a favour if your correspondent would deal with the question of the duration of life of this *Yucca*. The following passage occurs in a book on "The Wild Flowers of California."—"This (*Yucca Whipplei*) surpasses all known species in the height and beauty of its flower-panicles, but, once the season of flowering and fruiting has been consummated, its

life mission has been fulfilled, and the plant dies. The dead stalks remain standing sometimes for years upon the mountain side." Some interesting information is given in the same work about the uses to which the Indians put the plant. We are informed that the seeds are made into flour, that a soft white fibre used for making the linings of the coarse saddle blankets is made from another species, and the undeveloped flowering shoots (considered a great delicacy, either raw or cooked) are gathered and the leaves stripped off, leaving a round mass. This they "prepare after the fashion of a clam-bake." When the pile is taken to pieces and the cooked flowering stalks taken out they have much the same consistency as baked Apple and bear a slight resemblance to it.—S. ARNOTT.

PLANT VAGARIES.

It seems impossible to account for the vagaries of some hardy plants. How many of your readers, for instance, would dream of planting *Daphne Cneorum* in clay, with a dressing of dung and lime? It is the very last mixture I should have thought of using for this plant. A specimen 7 feet by 4 feet in rude health is exceptional and something to be proud of, and, according to "North Yorks" (p. 553), this development is the result of planting in clay enriched with manure, whereas a plant put into sandy peat and loam died. About a century ago the Lord of the Manor gave permission to the inhabitants of Woking to enclose an acre of ground each on Woking Heath. Many did so, and built cottages, which have nearly disappeared as the result of the builder's operations. Some forty years ago they still existed, and a feature of many of the gardens was this *Daphne*, which grew there like weeds. One of those cottagers said: "All I do is to tread down the shoots and put a spadeful of soil on them, and they make roots." Where the Railway Hotel now stands was a *Daphne* nursery, in which thousands of plants were raised and sent to all parts of the country. Could there be a greater contrast, then, between "North Yorks" clay and dung and the sandy peat of that district, and is it not strange that in his case, apparently, the addition of peat to the loam should have caused a plant to "promptly die"? This is quite contrary to my experience, as some years ago, finding that this *Daphne* would not thrive in my black soil, I made up a bed of loam, with lumps of peat and some leaf-mould. A fair-sized plant in the course of two years developed into a fine specimen, and I obtained between fifty and a hundred nice young plants. The propagating was simple. I bent the stronger shoots down, put a piece of peat on, and a stone on that. In the course of the season the peat was a mass of roots, so that, when severed, these young plants experienced no perceptible check.

One can understand that soil will influence the welfare of a plant, but it is puzzling when the same kind of soil appears to act in a quite opposite way in different localities. When I began the culture of *Gentiana aculalis* the plants refused to thrive, and gradually pined away. I tried another lot, with the same result. It happens that I have a piece of land which, although only separated by a hedge from where I live, is of a light, loamy nature, and it occurred to me to try it for this *Gentiana*. In less than a month the leaves took on a green tinge, and eventually I raised a nice lot of healthy plants from them. In this case it was simply a matter of soil. On one side of the hedge the plants died, on the other they were quite

happy. The common Parsley is very eccentric in its behaviour. There are places where it absolutely refuses to grow. With me it is luxuriant, but in a garden some 500 yards from me it will not prosper. The seedlings come up very well, but when the young plants get about 2 inches high the leaves turn yellow and no more growth is made. In one of the most famous gardens in England the same thing occurs. No expense has been spared, but no matter how well the soil may be prepared, every sprig of Parsley has to be bought. It is just the same with the Black Currant, which will not thrive there, in spite of careful soil preparation. Can anyone say why *Scabiosa caucasica* absolutely refuses to start with me? I have procured roots like moderate-sized Carrots, but they never showed the least sign of growth. One would think that by inherent energy they would have made some growth, even if the soil was not suitable for a vigorous life, but the same thing occurred even when I tried a complete change of soil. In the same way the *Doronicum* is practically biennial with me. In the third year after planting, it is not worth keeping. In the case of *Cyclamen Atkinsi* and *C. Coum* the seedlings come up and take on perennial vigour wherever placed.

Surrey.

BYFLEET.

MAY-FLOWERING TULIPS.

Now that the season is again with us for planting nearly all kinds of bulbs, a word may be said in favour of the tall-growing Tulips, which are not met with so frequently in gardens as their beauty and usefulness deserve. There are many who are always ready to add something of interest to their bulb garden or herbaceous borders, and it is in these positions the Tulips referred to find the best home, simply because they are or should not be lifted each spring the same as the dwarf-growing varieties generally used for spring bedding and window-boxes. It is certainly a mistake to plant what are known as the *Gesneriana* and breeder Tulips in ordinary flower-beds, where they have to be lifted directly they have passed out of flower to provide room for the summer occupants. They are not only not seen under the best conditions when used in this way, but, what is worse, the bulbs generally are of little value the following year, owing to having been disturbed before growth was properly completed and the bulbs matured. A permanent position should always be selected for them, and when massed in fairly large clumps they are unsurpassed during May for brilliancy of colour or for cutting. In

planting a collection of these it is best to prepare the ground thoroughly, as it is not desirable to disturb the bulbs afterwards. In selecting the different sites it should be remembered that many of the varieties send up flower-stems nearly a yard high; therefore, when planting in the mixed borders they should not be placed too near the front. It is always advisable to have the different varieties distinctly labelled; and to properly mark the exact spot where the bulbs are situated it is a good plan to drive in a strong stake that will stand out of the ground a few inches and which is stout enough to last for several years. Having marked the position in this way, from a dozen to thirty bulbs may be dibbled in round each stake, allowing, say, 4 inches space between each. Clumps formed in this way are easily supported to one neat stick before the tall flower-stems are fully developed to prevent them being twisted about by wind, which is not convenient to accomplish when each plant is separated some distance away from

its neighbour, while being massed they present a more pleasing feature.

Another important point in connection with these Tulips is that they flower in May and June, when it is yet too soon to expect much variety from the open borders, and, moreover, as they last for some time when cut, a good collection should be a boon to those requiring cut flowers.

NOTES AND REPLIES.

Increasing Anchasus.—I should be glad if you would tell me the best time to take root-cuttings of *Anchusa italica*. Dropmore var. and Opal that would make good plants to flower the following year.—MRS. GAGE HODGE.

[This work may be done at any time between November and February. Lift the plant, cut away as many roots as can be well spared, laying all in one direction, so as to keep the upper ends always uppermost. Any roots from the size of a Cedar-wood pencil to the largest available may be used, the roots to be subsequently cut into lengths of 1½ inches or thereabouts, keeping the ends that would naturally be nearest the crown of the plants always as the upper end. When the whole of the roots are cut into the above-named lengths, take some well-drained pots, seed-pans, or boxes of a sufficient depth, and having placed very sandy soil or Cocoa-nut-fibre therein, so arrange the pieces of roots that the top is just exposed to view. Well-drained flower-pots of 6 inches diameter will do quite well, each pot of this size being capable of holding a score of the root-cuttings by placing them at intervals around the inside of the pot. With the roots in position fill the central portion with sandy soil, and water to settle the whole. If you have a frame in a greenhouse where a temperature of 45 degs. or 50 degs. is maintained, the pots should be placed therein. Very little water will be required for the first few weeks, and growth from the apical portion of the root will appear in a month or six weeks. With more abundant growth give plenty of air, and subsequently transplant as you would seedlings prior to planting them out in the border in spring.]

The wild Clematis.—Having seen all my service in the East, I know nothing of English gardening. Last year I sowed a quantity of seed of *Clematis Flammula* in hedgerows in Essex, but none of it germinated. In spring I wish to plant from pots various kinds of hardy *Clematis* in hedges. I wonder if you would be so kind as to give me the names of one or two kinds that when established will look after themselves and possibly increase. *C. montana* grows wild in the Himalayas, and might become naturalised. I have tried various kinds of *Clematis* in my London garden here, but none has flowered satisfactorily. Even *C. montana* has produced no bloom.—MAIDA VALE.

[There should be no difficulty in getting on their own roots several of the wild *Clematis*—*montana*, *Viticella*, *flammula*, *orientalis*. They should be got from any good nurseryman, or may be raised from good seed, which, however, takes some time to grow. The graceful *C. Viticella* is easily naturalised, and *C. montana* may be seen on trees 40 feet high.—ED.]

The Peacock Iris (*Moræa Pavonia*).—What treatment should *Iris Pavonia* receive in the matter of soil and position? Is it necessary after flowering to cover the bulbs with glass, as in the case of the Cushion Iris?—ALPHA.

[Strictly, this is not an Iris; its correct name is *Moræa Pavonia*. Unless you are particularly favoured by warmth of situation or locality and have experience contrary to that we are about to recommend, this beautiful plant is calculated to give the best results when lifted each year soon after maturing and rested in dry sand for a month or two, replanting in September—

October or thereabouts, covering its station during severe weather with a mixture of Cocoanut-fibre and ashes. Better even than this would be to give it a hand-light to itself, where, with perfect drainage below, a rich sandy loam to root into, and an overhead covering to shield it from continuous wet, you would, with the lifting and resting already recommended, be doing your best to make it a success. A lover of warmth and sunlight, it should be catered for in these respects as well.]

Carnations.—There are, as is well known, some districts in which Carnations are more or less a failure, owing, perhaps, to some obscure condition of soil or of climate or of both combined. In such cases some measure of success may be attained by using seedling plants. If seeds be sown in August, the seedlings pricked off, and when large enough transferred to and wintered in 3-inch pots, they can be put out in early spring, will flower during the following summer and autumn, and can be discarded after flowering. This saves the worry connected with unhealthy layers in such gardens; and seedlings are equally as valuable for

ROCK, ALPINE, BOG, FERN, AND WATER GARDENS.

IRIS GRACILIPES.

If, among the dwarfiest of rhizomatous Irises, we accept *Iris cristata* and its white form as the embodiment of grace and charm and the lovely and distinct *I. tectorum* and its white variety as having a beauty of their own—albeit all too rarely seen at their best—there still remains room for the above miniature-growing Japanese alpine kind, whose elegant grace must appeal to all. Briefly, it may be likened to a miniature *I. tectorum*, a likeness suggested chiefly by the prettily fimbriated flowers, which are pale blue in colour with orange crest. It is too dwarf and choice for ordinary border cultivation, and should be given a place in the rock garden, where in a cool root-run of sandy loam it will usually give a good account of itself. The habit of growth and flowering are well shown in

Iris gracilipes.

decoration or for cutting as are named varieties.—Krr.

Primula nessensis.—This Chinese Primula, introduced in 1911 by Messrs. Bees, from seeds sent home by Mr. George Forrest, is appreciated by those who have grown it. It is one of the denticulata section, the flowers of a pretty pink colour and on stems of good length. It makes a good pot plant for the greenhouse, and it can also be grown out-of-doors in a rather moist position.—S. A.

Squirrels in the garden.—Never, I think, have I seen so many squirrels in the garden and its neighbourhood as during the past month. I cannot say that these animals are a source of danger to plants generally, although they are accused by foresters of spoiling certain kinds of young and newly-planted trees. At any rate, I have kept them under close observation for years, and the utmost with which I can tax them is a partiality in some seasons for Morello Cherries. This, I fancy, is more for the sake of the kernel than for the fruit of such. Of course, they are very partial to the haws of the Thorns, but as birds also are fond of these, the squirrel need not be grudged a share.—W. McG., *Balmac.*

the accompanying illustration, to which may be added that the plant grows 6 inches to 9 inches high and flowers in late spring. Not very robust, and still far from common, it is worth the best endeavours of the hardy plant gardener to make it a success. E. H. J.

TRAILING PLANTS FOR THE ROCK GARDEN.

FROM the abundance of trailing plants which can be employed in the rock garden we may select a few for notice, as useful, pretty, and of easy culture. These do not by any means exhaust the suitable subjects, but they will be found to suit most gardens and to thrive in almost all parts of the kingdom. They will, with few exceptions, do well in a mixture of light loam, or loam, leaf-soil, and sand. Plenty of stones about their roots will suit most of them, and firm planting is always desirable.

The most of the *Acænas*, or New Zealand

Burs, are pleasing. Among the best are *A. Buchanani* and *A. Nova-Zealandia*, which are prized more for their foliage than for their flowers. They will thrive in sun or shade, but prefer a little shade. The *Æthionemas*, or Lebanon Candytufts, are good for low stones; they like sun, and should have some lime in the soil. *Æ. grandiflorum*, with rosy flowers, is one of the best for our purpose. *Alyssum serpyllifolium* (yellow) looks well as a low trailer, while *A. spinosum* (white) has also silvery leaves, and a big plant will cover a stone 2 feet or 3 feet high in due course. *Androsaces* are gems for the rock garden, but the best for the object we have in view is *A. lanuginosa*, which blooms a long time and likes a little lime in the soil. In moist districts it should be protected from wet in winter. *Aubrietias* are invaluable. *Arenaria balearica* will cover a moist stone very rapidly, and should be planted at the foot to clamber up. *A. montana* is a grand, white-flowered trailer and a beauty in spring and early summer.

In several of the *Campanulas* we have capital plants. Among the best are *C. portenschlagiana*, *C. garganica*, and *C. g. hirsuta*. These are blue, but there are white varieties of *C. garganica*. *Cerastiums* are indispensable for larger rockwork, but they must be kept in bounds. *Coronilla iberica* is a nice, yellow-flowered trailer, liking full sun and a rather dry, stony soil. Nice little trailing shrubs are *Cotoneaster congesta* and *C. humifusa*, their deep green foliage and small flowers, followed by pleasing berries, making these *Rocksprays* attractive. Then such dwarf *Brooms* as *Cytisus Ardoini*, *C. decumbens*, and *C. kewensis* (creamy) are all gems for our purpose, and we may add *Genista prostrata* and *G. sagittalis*. For the rock garden the *Pinks* are very fine. *Dryas octopetala* (white) is good, and prefers a little lime in the soil. Give it sun. The winter-flowering *Erica carnea* is excellent. *Gypsophila prostrata* and *G. repens* are excellent with their white or rose flowers, and any of the *Sun Roses* will be found delightful for sunny rock gardens, and give many-hued blooms in profusion. *Hypericum fragile* (yellow) is a good *St. John's Wort* for a sunny or shady rock. In practically all the perennial *Candytufts* we have useful white-flowered subjects for our purpose. *Lithospermum prostratum*, which, however, does not do well everywhere, is a gem with blue flowers, and for a shady, moist spot the common *Creeping Jenny*, *Lysimachia nummularia*, or its golden-leaved variety may be employed to advantage. *Phloxes* of the *setacea* or *subulata* class, with *P. Stellaria*, are invaluable for spring. Keep them pretty well up on the rockwork, where they will get some sun. *Polygonum Brunonis* (rose) is good for autumn, and *Saponaria ocyroides* is capital for a dry, poor soil in sun. The flowers vary from rose to almost crimson, according to the variety. All the *Mossy Saxifrages* are excellent. *Silene Schafta* (purple-rose) is capital in sun or shade. We may also plant in sunny places any of the *Thymes*, the varieties of *T. Serpyllum* being as pleasing as any. *Tunica Saxifraga* (pale rose) is a gem for a place where only a thin veiling is required. Dry, stony soil in sun suits it well. *Veronica prostrata* and *V. pectinata rosea* (the former blue and the latter rose) are excellent, and the *Vincas*, or *Periwinkles*, will soon cover a large space with their pretty leaves and flowers. In *Waldsteinia fragarioides*, which does best in a moist, shaded position, we have a beautiful yellow-flowered plant with glossy leaves and pleasing flowers.

S. ARNOTT.

FERNS.

HARDY FERNS IN WINTER.

OUR native hardy Ferns belonging to two categories, viz., those which are deciduous and die right down to the ground in the late autumn, and those which are evergreen and retain their fronds until the succeeding season, it is evident that, under glass at any rate, the latter may be arranged to preserve to a considerable extent the attractiveness of a collection through the dead season of the year.

With regard to the former, the fact that the fronds fade and shrivel in the autumn is not infrequently regarded as a sign of actual death through some mysterious cause, the persistent greenness of the other species helping this conclusion. It is, however, a purely natural feature, and we see precisely the same phenomena in our deciduous and evergreen trees. Even to those, however, who recognise this fact, there is a great danger that the seemingly empty pots, so far as visible life is concerned, may be neglected during the long winter months as regards the all-essential point of watering. If we study such Ferns in their native habitats we shall find that during the winter they exist under the moistest possible conditions, being more or less buried in the wet débris of their own fronds and dead leaves from other sources and with the soil thoroughly saturated. Hence we may learn that even in their dormant condition the roots should never get dry, and thus that occasional watering is essential. If the room occupied by the pots be needed for other purposes they can, owing to the thorough hardness of the Ferns, be buried in soil outside or packed in cold frames until the early spring when new growth commences. These remarks apply to the Lady Ferns, *Lastrea filix-mas*, *L. montana*, *L. propinqua*, and *L. Thelypteris*, the Royal Fern, the Bladder Ferns, the Oak and Beech and Limestone Polypodies, and the Bracken, the fronds of all of which disappear by November.

The evergreen species are far more numerous, and consist of the Shield Ferns, all the Spleenworts, the Harts-tongue, *Blechnum*, *Lastrea semula*, the common Polypody and the filmy Ferns, to which may be added, under glass, the hard Male Fern (*L. pseudo-mas*), and with a little coaxing by way of support, the Broad Buckler Fern, which, with its sub-species *L. spinulosa* and *cristata* forms a sort of intermediate link, since though the fronds drop down as a rule, they retain their verdancy until the spring. The varieties of all these species retain their specific habits in this respect. Hence we see that, provided the plants have been healthy and free from vermin, there remains a large group of evergreen ones for the decoration of the fernery during the otherwise dead season. As under Nature all these species occupy moist habitats in the winter, occasional watering, as we have said, is essential, but it is not advisable to keep the frondage wet under glass by overhead watering.

In the open, under the stress of frost, wind, and heavy rains and snow all the Ferns, whether evergreen or otherwise, are apt to get beaten down and rendered unsightly, but it is not wise for mere neatness' sake to remove the fronds, even the dead ones, as they constitute the natural protection of the crowns from the weather, and it is better to give them generally a liberal mulching of dead leaves such as they usually get in their native habitats. This protection should be left until the end of March, when the risk of drying winds and sharp frosts is reduced, and even then it is well to leave the mulching

close around the crowns, and for this special reason, each budding frond commences operation by emitting a fascicle of roots on its own account from its base, and until these have well penetrated the soil under such protection, they may be injured by its removal and seriously check the growth for the season.

The principle, indeed, to be borne in mind throughout is that the roots are alive and it may be actively active, though the visible growth is at a standstill, and the maintenance of this vitality by avoidance of drought is a *sine quâ non* of successful culture.—C. T. DRURY in *British Fern Gazette*.

GARDEN FOOD.

NOTES AND REPLIES.

A self-blanching Celery.—My crop of this is not quite good to look at, poor in colour, and the report from the kitchen is that it is good for soups and stews. Even for that purpose it is useful and helps to save the great labour of Celery-growing. Have any of your readers success with it?—W.

Arran Chief Potato.—I neglected to plant this in the garden, and, hearing a good report of it, I had some from the farm, and like it well for the one essential need, good flavour. It is a large, round Potato, and said to be disease-resisting and first-rate baked or boiled. My favourite hitherto has been Langworthy, but it will have to give place to Arran Chief.—W.

Home-grown Celeriac.—My roots are not so large as those seen in markets from abroad, but distinctly better in flavour, no matter how cooked. The coarse market roots were not so easily cleaned. In vegetable stews, in casserole among other things, around game, or as a separate dish with brown sauce (as in France), it is the best winter vegetable of the season.—W.

Prunes as food.—Among the best foods for winter use is the Prune, often ill-grown from European sources, very good, as a rule, from California. There is no good reason why Prunes of best quality may not be grown in the warmer parts of our islands, always where the soil suits. When we have a good stock of fruit ready for the cook an essential point is to soak the fruit so as to remove the manufactured sugar, mould, etc. The full advantage of the fruit is not to be had other than from the natural sugar and aids of the Prune.

Potato British Queen cooking badly.—Once one of the most reliable of croppers and best of cookers, this well-tried variety appears to have fallen on evil days. That it should not crop quite so heavily as once it did may be explained, but where has its dry, mealy property gone to? For two or three years I have grown British Queen in various soils and it has invariably been disappointing, boiling into a sloppy mess before the tuber is cooked to the centre. Up-to-Date offended very grievously in this respect for several seasons, and it is not quite satisfactory yet, especially in autumn.—A. T. J.

Garden Swedes and macaroni.—Swedes are very useful to the cook these days, better than most Turnips. The name is given to a compact form of the common Swede. Small roots from the field do as well, but it is often handy to have a little plot in the garden. Combined with other good things, macaroni to wit, they are very welcome cooked as follows:—Into a saucepan of boiling water put a pinch of salt, and break six ozs. of macaroni and cook for forty minutes; then allow it to drain in a colander. Meanwhile cook two small

Swedes. When done, drain off the water and pass through a sieve. If the pulp is too thick add a little cream; return to the pan with macaroni, a small piece of butter, season lightly to taste, and serve hot.

COOKING FIGS.

FIG DUMPLINGS.—Mix two cupfuls of flour with half a teaspoonful of salt, one teaspoonful of baking powder, and two tablespoonfuls of sugar and sift into a basin. Add three-quarters of a cupful of chopped Figs, and sufficient milk to make a stiffish dough. Divide the mixture into six equal parts, shape them into dumplings, drop them into a saucepan of boiling water, cover, and cook for one and a half hours. Drain and serve hot with any preferred sweet sauce.

STEAMED FIG PUDDING.—Chop half a pound of Figs rather fine and put them into a saucepan with one cupful of milk, to cook for fifteen minutes. Put into a basin one cupful of breadcrumbs or cracker crumbs, half a cupful of flour, a quarter of a pound of finely chopped suet, half a cupful of sugar, and a quarter of a teaspoonful of grated Nutmeg, mixing well together. Add the Figs and the milk, then beat up two eggs and add them with one teaspoonful of baking powder, mixing all together. Pour into a buttered mould, cover with a buttered paper, and steam steadily for two hours. Turn out and serve with any preferred sweet sauce or hot milk.

COMFOTE OF FIGS.—Wash and dry one pound of good Figs and arrange them in a glass dish. Boil two cupfuls of water with half a cupful of sugar for fifteen minutes, then add the strained juice of one Lemon. When cool, pour over the Figs; allow to get cold. Garnish with whipped and sweetened cream flavoured with half a teaspoonful of Lemon extract, pressed through a forcing bag with fancy tube. Serve with cream.

FIG ROLY POLY PUDDING.—Rub into four cupfuls of sifted flour a quarter of a pound of finely chopped suet, add a pinch of salt, two teaspoonfuls of sugar, one teaspoonful of baking powder, and make into a stiff paste with a little cold water; roll out and fit into a well-buttered pudding basin, letting the edges hang over. Put into the basin a layer of Fig jam, cover with a layer of paste, and so on until the dish is full; cover the last layer of jam with the overhanging paste, cover with buttered paper, and steam steadily for three hours. Serve with hot milk.

FIG MOULD.—Take half a pound of good Figs and wash them well, add the grated rind of one Lemon, four tablespoonfuls of sugar, and one cupful of water. Put all into a jar, cover with a piece of white paper. Place in enough boiling water to go half up the jar. Stew very gently until the liquid is dried up and the Figs very soft. Press into a wet mould, turn out, and just before serving pour custard sauce round. To make the custard sauce: Put into a saucepan the yolks of four eggs, four tablespoonfuls of sugar, and one and a half cupfuls of milk. Stir until it thickens and then add half a teaspoonful of Lemon extract; strain and use.

FIG DELIGHT.—Beat up the whites of three eggs to a stiff froth, then beat into them half a cupful of sugar; add half a cupful of sugar to the yolks and beat for five minutes. Mix the two together and stir in one cupful of flour sifted with one teaspoonful of baking powder. Bake in a well-buttered shallow pan. Beat up the white of one egg, add enough powdered sugar to make a soft frosting, then add eight large Figs chopped fine, twelve Raisins seeded and chopped, and twelve blanched and chopped Almonds. Spread over the cake and roll up. Serve cold in slices.

TIMBALE OF FIGS.—Put one pound of dried Figs into a saucepan, add half a cupful of Orange juice, one cupful of water, four tablespoonfuls of sugar, and the grated rind of one Lemon. Simmer gently until the Figs are tender and the moisture nearly absorbed, then rub the mixture through a sieve. Dissolve one and a half tablespoonfuls of gelatine in half a cupful of boiling water and stir it into the Fig mixture. Add four tablespoonfuls of whipped cream and pour into a wet mould. Turn out at serving time and decorate with roses of whipped cream.—Country Gentleman.

TREES AND SHRUBS.

PECULIAR TREE-GROWTHS.

THE accompanying illustration shows a peculiarity of growth that is more common in the case of the Beech than in other

perhaps, the most pronounced case of in-arching that has come under my notice will be found in the second volume of "Woods and Forests," at page 69, where the present writer, in some tree notes from the Conway Vale, illustrated a peculiar tree-growth. As will be seen from the

quently in the Beech than other trees is not readily accounted for.

A. D. WEBSTER.

SOME ATTRACTIVE DAPHNES.

THE Daphnes are composed of evergreen and summer-leaving shrubs, the majority

Curious tree growth near Broadway, one branch of each tree having grown into the trunk of the other. From a photograph sent by Miss M. Leventon, Bangor.

trees. An almost parallel instance to this occurs in the famous "Derby" Beech at Holwood, in Kent, in which at 40 feet from the ground two branches have become in-arched or connected with the main stem. By the Regent's Canal, near the North Bridge, another example of this kind is well known to observant visitors. But,

sketch, the branch forms quite an elbow or loop with the main stem, and is so uniform in size throughout as to puzzle one to say whether the branch sprang from above or below. It is the result of in-arching, but whether naturally or artificially brought about is impossible to say. Why cases of inarching should occur more fre-

of which are interesting by reason of their fragrant and often-times showy flowers. A few species are natives of Asia, and one, *D. cannabina*, is of economic importance, for in Northern India its bark is utilised for the manufacture of paper in the same way as the bark of the closely-allied plant, *Edgeworthia papyrifera*, is used. The

most important species, from a garden standpoint, are natives of Europe, where they are usually found in alpine regions, although some affect low elevations, and one or two are wild in the British Isles. They are peculiar plants under cultivation, for in some gardens they grow like weeds and give little or no trouble, whilst in other gardens a good deal of difficulty is experienced in their culture. Soil is not always the deciding factor, for the same species may be found doing well in peaty soil in one place and in heavy loam in another, while an attempt to introduce either condition into a third locality may result in failure. Constant moisture at the roots without a water-logged condition of the soil is essential, and many of the species require lime. It is always wise to raise plants from seed whenever possible, for such plants give better results than those raised in other ways, but in some instances seeds are difficult to obtain. Then the branches of some kinds may be layered, others may be increased by division; in only a few cases is propagation by cuttings a satisfactory method, whilst grafting is often practised. Grafting, however, is not always a very successful method; although the scions take well, the plants often die off suddenly. The reason for this may be the unsuitable character of the stock, a deciduous stock being used for an evergreen species or an evergreen stock for a summer-leaving kind. The more vigorous Daphnes are useful for planting in beds or borders in the ordinary way, but the dwarfier kinds are usually seen at their best when planted in the rock garden, where, once they become well established, they will remain in good condition for many years, their roots being less liable to disturbance than would be the case were they planted in borders with other plants. In the following notes attention is directed to only the more important species:—

D. ALTAICA is a very dwarf shrub from the Altai Mountains. It is summer-leaving and bears small heads of fragrant white flowers during May and June. It is allied to *D. caucasica*, and is sometimes associated with that species as a variety. The two are now, however, kept separate, *D. caucasica* being a larger-growing shrub, attaining a height of 3 feet or 4 feet. It also bears fragrant white flowers during late spring and early summer.

D. BLAGAYANA has for many years been one of the most famous alpine plants in the Glasnevin Botanic Garden, where it does well growing amongst rocks. A native of the European Alps, it has been in cultivation since 1875, but is not a common plant. Ranging between 6 inches and 12 inches in height, it spreads by means of underground stems. The leaves are evergreen. The cream-coloured flowers, borne in fairly large terminal heads during spring, are very sweet-scented. The secret of success with this plant is said to lie largely in keeping the shoots close to the soil by means of stones. Loamy soil appears to suit it best.

D. CNEORUM.—This species, known by the common name of Garland Flower, is one of the most beautiful of all and one of the most capricious. In some gardens it gives no trouble, while in other places it seems impossible to get it to grow. In *GARDENING ILLUSTRATED* for November 4th "North Yorks" describes how he grows this plant remarkably well in newly-dug clay with a very little top soil. He had it planted also in sandy peat and loam, but it then died. A few years ago one of the most successful growers of this plant, Mr. Knowles, at that time a nurseryman near Woking, grew very large quantities in the

ordinary soil of the district, sandy peat, and grew them well, hence the difference. People who have tried to imitate the Woking conditions have failed. Therefore it appears that the only way to find out whether the plant will grow in a certain garden is to experiment with it. Rarely rising more than 9 inches above the soil, it forms a spreading mass, increasing by underground stems. The evergreen leaves are small and narrow, and the pretty rose, fragrant flowers are borne in round heads from the points of the shoots during May and June. The variety *Verloti* is more vigorous than the type. Both plants are excellent for the rock garden or for beds on the lawn.

D. GENKWA is too tender for outdoor culture in the British Isles, except in a few favoured localities. A native of China and Japan, it forms an erect, deciduous shrub 3 feet or so high. The lilac flowers are borne in clusters from side buds in advance of the leaves during early May, the inflorescences reminding one strongly of miniature heads of flowers of the Lilac. At its best it is a very effective plant, but it is rarely found as a well-developed specimen.

D. HOUTTEANA.—This is said to be of hybrid origin, its parents being given as *D. Mezereum* and *D. Laureola*, the one summer-leaving and the other evergreen. It is semi-evergreen, grows 2 feet or so in height, and bears lilac flowers. As a rule, it grows well and gives better results than some of the others, although less beautiful than some of the species. It is sometimes called *D. Laureola purpurea*. The leaves are deeply shaded with purple.

D. LAUREOLA (the Spurge Laurel) is one of the British species, being found wild in a few localities. It is evergreen, with rather attractive leaves, from the axils of which yellowish-green flowers appear during late winter. Mature plants may be 2 feet or 3 feet high. The variety *Philippi*, from the Pyrenees, is of dwarfier and more compact habit, with smaller leaves.

D. MEZEREUM.—This, the *Mezereum* of the British Isles, Europe, and Siberia, is one of the most useful and attractive of all the Daphnes. Usually growing about 3 feet high, it forms a shapely bush with erect branches clothed with lance-shaped leaves. The flowers are borne in February and March from almost every bud on the previous year's growth. The colour is red and the flowers are very fragrant. There are two distinct varieties—*grandiflora*, which blooms during winter and bears larger flowers than the type, and *alba*, with white flowers. In addition to the flower beauty of these plants they are also very attractive when the fruit is ripe, that of the type being bright red and that of the variety *alba* yellow.

D. NEAPOLITANA thrives fairly well in many gardens. It is said to be a hybrid and is distinguished by its bushy habit, slender shoots, and small leaves. The purplish flowers are fragrant and are borne from near the points of the shoots in May. Fully-grown bushes may be as much as 3 feet high, though it is often much dwarfier.

D. ODORA is a well-known evergreen shrub which in many parts of the country is grown in a cool greenhouse, though in the warmer parts it grows quite well out of doors. A native of China and Japan, it was introduced as long ago as 1771. In gardens it is often called *D. indica*, and is frequently grafted upon stocks of *D. Mezereum*. This, however, is not really necessary, as it can be rooted from cuttings, which, as a rule, form the most satisfactory plants. The flowers are very fragrant, whitish within and reddish-

purple without, and appear over a long period, being often at their best during winter. There is a variety with white flowers. *D. Dauphini* is a hybrid between *D. odora* and *D. collina*. It is a free-flowering plant and rather hardier than *D. odora*.

D. PETRÆA.—Attention has been directed to this species on several occasions during the last few years. It is a very dwarf shrub with short, contorted branches, rarely growing 6 inches high. The leaves are small and evergreen, the flowers fragrant and an attractive shade of pink in colour. The flowering time is June, and the most suitable position for this shrub is the rock garden. It is also known as *D. rupestris*.

D. PONTICA is another hardy evergreen bush 3 feet or so high. The leaves are up to 3 inches in length and rather light, glossy green. The fragrant greenish-yellow flowers are produced in April. It is of more value as an evergreen than as a flowering shrub.

D. RETUSA is a Chinese shrub with evergreen leaves. It grows a foot or more high and branches freely. The white, purple-shaded flowers are borne in May and are very fragrant. It is a good plant for the rock garden, and is well worth special attention. D.

NOTES AND REPLIES.

The Constantinople Nut or Turkish Hazel (*Corylus Colurna*).—This is the best known of the Tree Hazels, and good examples of it are occasionally found in old gardens in the South of England. It is a native of S.E. Europe and Asia Minor, where it grows 50 feet to 80 feet high, with a trunk sometimes exceeding 1½ feet in diameter, the wood being rather heavy, close-grained, and of good quality. Even in this country there are trees 50 feet or so high, with large trunks. The male catkins are yellow and 3 inches to 4 inches long, and the small red female flowers are very like those of other Hazels. The Nuts are rather smaller than those of the ordinary Hazel, being wider, but shorter; moreover, the shells are very thick, and the kernel small. The husk, however, is the conspicuous part of the fruit, for it is large and covered with soft, gland-tipped spines. It is a good tree for a lawn or in a conspicuous position in a park, and it thrives in well-drained, loamy soil. Layered branches can be used for propagation, whilst it can also be raised from seeds.—D.

The Himalayan Lilac (*Syringa Emodi*).—Where a strong-growing shrub of the largest size is desired, this might well be tried, for it grows 15 feet to 18 feet high, with a number of strong main branches bearing numerous secondary branchlets, which carry ample and attractive leafage. The flowers, borne in panicles up to 6 inches long in June, are white or white tinged with pink, but they are not fragrant as in the common Lilac. It can be grown in most parts of the country, especially as it is not fastidious regarding soil. It is easily increased by seeds, which ripen freely here.—D.

Escallonia pterocladon.—This is probably the most generally hardy species, and as such worth the attention of all who delight in choice shrubs or evergreens suited to walls or other places in gardens in favoured localities. Of more lax habit than some, it is distinct in its neat growth, and long spikes of small white flowers, which are not unlike those of the *Colletia* in form, and furnishing the stems with some freedom, are pretty against the small shining leaves.—J. S.

"The English Flower Garden and Home Grounds."—New Edition, 12th, revised, with descriptions of all the best plants, trees, and shrubs, their culture and arrangement, illustrated on wood. Cloth, medium 8vo, 15s.; post free, 15s. 6d. Of all Booksellers or from the office of *GARDENING ILLUSTRATED*, 63, Lincoln's Inn Fields, London, W.C.

INDOOR PLANTS.

CARNATION NORA WEST.

SEEING that this variety gained an Award of Merit from the Perpetual-flowering Carnation Society when exhibited by the raiser in December, 1915, and when inspected in March, 1915, at the raiser's nurseries by a sub-committee of expert growers was granted a First-class Certificate, should go a long way to stamp it with the hall-mark of excellence. The dates of the awards, December, 1914, and March, 1915, are significant and of some moment. With a specially grown stock and numbers to select from, it were easy enough to pick a dozen or two well-flowered examples, and so gain the award in the earlier year named. It was quite another matter to be able to secure the higher award after inspection of the stock at home in March, 1915. March flowers are unmistakably the product of growth made during the worst months of the year, and,

of amateurs who specialise in the Carnation, it also bids fair to take a prominent place among the leading commercial varieties of the present time. It was raised by Mr. George West. E. H. JENKINS.

HARDY PLANTS FOR SPRING BLOOMING.

We have become so accustomed to rely on bulbs for a spring display that, if the truth be admitted, we have almost forgotten that many of our hardy plants will respond to gentle warmth and may be lured into bloom some time in advance of those out of doors. I use the term "gentle warmth" advisedly, as forcing as we regard it in these days of intensive culture is neither advisable nor essential. In these times, when, through shortage of the bulb supply from the Continent, or may be for financial reasons, it is not possible to place our usual order, it would be well to take an inventory of one's own garden in order to see whether we cannot provide for a dis-

and the deeper tints of Anthony Waterer. Of white-flowered plants one thinks of *Deutzia gracilis*; of the quaint ivory appendages underneath the arching leaves of Solomon's Seal. Quick of growth is *DieLytra spectabilis*. We admire the single and double *Pyrethrums* in the borders in June, but few think of what these old-fashioned things are capable as indoor plants. LEANURST.

THE CAPE PELARGONIUMS.

CONSIDERING the various ways in which sweet-scented Pelargoniums can be used, the wonder is that they are not more grown. Whether for mixing, when cut, with cut blooms in glasses, associating with such flowering plants as Carnations or bulbs grown for winter decoration, during the summer months as bedding plants for toning down some of the gaudy colours so prevalent in flower gardens, or for wreaths or button-holes, what so useful or appropriate? There is also such a variety of shades and diversity of form in their foliage that the most critical will find among them something to please. The scent of the foliage, too, with the exception, perhaps, of some of the *quercifolium* forms, is very agreeable, and in the case of many of them enjoyable and refreshing. True, they have not such gaudy flowers as the regal and Zonal Pelargoniums, but considering that they are of the most use as fine-foliaged plants, this is rather an advantage than otherwise, as the colour of the flowers is not sufficiently prominent to clash with that of those they may be mixed with. Each variety has a beauty of its own, and a good collection in flower is most interesting. Regarding their

CULTIVATION, no great amount of skill is needed. Some of the varieties are rather difficult to increase, but the generality of them are easily struck from cuttings. For the variegated varieties and some of the finer sorts a little extra trouble is needed. The cuttings should be inserted in small pots filled with a mixture of loam, leaf-mould, and sand. Any corner in a cool, airy, but not draughty pit will suit the cuttings until they have rooted. Shade from bright sunshine at first and give an occasional sprinkling overhead, but on no account allow the pots to become soddened with water. After the cuttings are rooted the usual shifting on is necessary, using the same kind of compost as that in which the cuttings were inserted, only coarser. If the plants are required for winter work they can be grown out-of-doors during the summer. Take care that the plants are not allowed to suffer from want of water or that they become root-bound. Pinch them or allow them to grow according as tall or bushy plants are required. By the end of September or early in October they should be shifted into their flowering pots, which should vary according to the growth of the varieties. Some of the dwarfier sorts, such as *denticulatum*, *Wardie Seedling*, *Lady Plymouth*, *quercifolium*, *coccineum*, *radula*, *Little Gem*, etc., are of most use for front rows, and should, therefore, be kept in smaller pots, while *P. viscosissimum* and other taller-growing sorts can be put into 8-inch or smaller pots, according to the size of the plants. After the plants have filled the pots with roots, weak manure-water will assist them. They should be housed by the middle of October and placed where they can have a good circulation of air, also as near the glass as possible. Under such conditions and with ordinary attention to watering they will make a sturdy growth throughout the winter, and will come into flower early in spring. A cool, airy atmosphere (say between 45 degs. and 50 degs.) is indispensable if a healthy growth is to be main-

Carnation Nora West.

seeing that such growth made in the Thames Valley (Datchet) met the approval of the examining committee speaks volumes for what I regard as one of the best of modern British-raised Carnations. Those who know from long experience the behaviour of the Perpetual-flowering Carnation in low-lying valley districts adjacent to a river will be able to appreciate the good attribute of winter flowering in the new comer. As a seedling from Winsor, one of the best of the true pinks which came early from America, it will also appeal. It is, however, superior to the old variety named in colour, and in refinement—not a strong point in Winsor—vastly improved. The clear, deep salmon-pink of the flowers appeals to one, and generally in flower freedom and continuity, petal quality, and other ways it is of outstanding merit. The habit, too, is excellent, and, what will appeal strongly to the amateur, the plant is healthy and the variety an easy doer. In fine, while it is calculated to please a large proportion

of welcome flowers in the spring time. Necessity often throws us back, as it were, on substitutes, and these sometimes surprise us. He who will give hardy plants a trial by potting them up, keeping them cool until spring, and afterwards inuring them to a slightly warmer atmosphere will appreciate what many of our familiar border plants are capable of doing under glass. It is when they are subjected to a high temperature that they fail, and, in consequence, are thought to be unsuitable for indoor culture. It is not the fault of the plant, but of the treatment. In our gardens we shall find abundant material for our purpose, and though the time of flowering may be a little later than in the case of the bulbs we have been in the habit of potting, their diversity of beauty is pleasing in the early year, and provides a galaxy of colour before the garden flowers appear. Such are the white and blue *Bell-flowers*, and the *Canterbury Bells*, *Spiræas* in variety, from the old form of *japonica* to the pink spikes of *S. Douglasi rosea*

tained. After the plants have served their purpose during the winter in the greenhouse they can be planted out in May in a mixed border, and the foliage cut for mixing with other flowers through the summer.

ABUTILONS.

ABUTILONS are met with much less in gardens than was formerly the case. This is a pity, as, given greenhouse treatment, they will flower more or less continuously throughout the year. As bearing out that they are now much neglected, I was recently assured that there is little or no demand for them now. The different kinds are very useful in many ways. In the first place, they are very suitable for training to the roof of the greenhouse, as in this way the pendulous nature of the bell-shaped blossoms enables them to be seen at a very great advantage. Next, for clothing the pillars in the same structure they are well suited, and if planted out so as to get a fair amount of root room some of them will soon mount up to a considerable height. Good examples, too, may also be grown in pots. Now that standard plants are very much in vogue Abutilons are well suited for this mode of culture. In this way their drooping blossoms may be brought much on a level with the eye. Stopped once or twice when young, many of the garden varieties will make neat bushes, and when laden with flowers they are very pleasing. Some of the species, such as *A. igneum*, *A. striatum*, and *A. venosum*, are of a free-climbing habit, while the small-leaved *A. vexillarium* or megapoticum must not be omitted from the climbing section. Other good kinds to grow as bushes, roof plants, or standards are Anna Crozy (purple), Boule de Neige (white), Eureka (pink), Future Fame (crimson), Golden Fleece (yellow), Gold Kafir (orange), Royal Scarlet (bright red), and Sanglant (deep red). The pink variety, *Triomphe*, which was given an Award of Merit in 1915, has very large flowers.

W. T.

THE OLDER GREENHOUSE PLANTS.

FASHIONS change in plants as well as in other things, and what is appreciated by one generation does not find favour with another. Especially is this the case with greenhouse plants, as those of us who can look back upon the experiences of three decades among them will not, without regret, admit. In these days it is a desideratum of a greenhouse plant that it be showy, quickly grown, easily managed, and, above all, easily replaced in the event of accident. All these qualities are certainly valuable, and it must be admitted that since the revival of the interest now shown in the outside garden the greenhouse has taken but a secondary position, except, perhaps, for a month or two in the depth of winter.

Nevertheless, one may still have a warm side for some of the older greenhouse plants which, at one time, were highly valued, and of which the culture presented more difficulties to the grower than the ephemeral plants of to-day. In some places specimens of some of these old favourites, *Diosma* or *Aloysia*, for example, may be retained for sentimental reasons, but, generally speaking, the newer school of greenhouse gardeners has little knowledge of them except by name, and sometimes they have not even that knowledge. How often now does one come across the two plants just named, or the Oleanders, which used to be found in every greenhouse or conservatory of any pretensions, grown generally in tubs, and very attractive in their season? Few grow the old *Fuchsia fulgens* now, or *Hoya carnosa*.

Diplacus glutinosus is by no means common, nor is *Libonia floribunda*. The old double *Primulas* and *Cinerarias* are rarely met with, bush examples of the *Habrothamum* (*Cestrum*) still more infrequently. *Begonia Weltoniensis* still lingers; so, too, does *B. fuchsoides*, but in decreasing numbers. The old balloon-trained specimens of *Rhynchospermum jasminoides* and of the *Lapagerias* have disappeared; the cherished plants of Myrtle are found no longer. The *Metrosideros*, *Banksias*, and *Bossias* are unknown in present-day greenhouses. Aloes and Agaves have gone, although their disappearance is not entirely a matter of regret, and the *Dryandras*, grown more particularly for their foliage, are but a memory. The berried *Solanum* yet lingers in some places, although it is now chiefly grown by market men, who find a ready sale for it at Christmas. *Humeas* may yet be found, but rarely, and the greenhouse *Statice*s are not often met with in modern collections. How many young gardeners can say that they could identify *Lisianthus princeps*, one of the most beautiful of the almost forgotten plants, with its long, tubular flowers, each almost 5 inches in length, bright crimson, and tipped with orange? The *Chrysanthemum* has undoubtedly been responsible for the disappearance of these old-time favourites, but, perhaps, it is not too much to hope that, sooner or later, the older greenhouse plants may again be restored to favour.

A SCOTTISH GARDENER.

NOTES AND REPLIES.

Winter-flowering Begonias.—In the article on this subject in *GARDENING ILLUSTRATED* for November 18th it is stated that Messrs. Veitch, of Chelsea, were the first to take these Begonias in hand, and they raised many fine varieties. No mention is made of some very fine forms raised during the last few years of their carrying on the business, except to claim one of them, *Optima* (clear salmon), as having been raised by Messrs. Clibran. The variety *Elatior* (rosy-carmine) is also one of Messrs. Veitch's, though of an older date. The desirable forms above alluded to first made their appearance in the autumn of 1911, when four of them gained awards of merit. These varieties, all of which are single-flowered, show closer traces of the tuberous-rooted section than those that had gone before. The flowers, too, are larger, while the growth is sturdy and the foliage bold. The first four of this section are *Acquisition* (pink, suffused salmon), *Exquisite* (salmon-pink), *Fascination* (orange-salmon with a suspicion of pink), and *Her Majesty* (rich coppery-orange). In 1912 similar honours were gained by *Emita* (brilliant orange-scarlet) and *Optima* (clear salmon). The only semi-double variety mentioned above is *Elatior*, the remainder being quite single. On the other hand, nearly all the varieties raised by Messrs. Clibran have double or semi-double flowers; indeed, in the production of flowers of this class they stand as high in recent years as did Messrs. Veitch for giving us these delightful single ones. The double-flowered *Clibran's Pink* is, in the report of the Royal Horticultural Society's meeting on November 7th, alluded to as one of the best winter-flowering Begonias ever raised, the colour good, the blossoms shapely and refined.—K. R. W.

Winter-flowering Carnations at Springburn Park, Glasgow.—Among the things specially well done at Springburn Park, Glasgow, are the Perpetual-flowering Carnations, which are always an object of admiration by visitors. The leading varieties—old and new—are excellently grown.—SCOTSMAN.

VEGETABLES.

SPROUTING SEED POTATOES.

(REPLY TO "A. M. M." AND ALPHA.)

The sprouting of seed Potatoes is seasonable, inasmuch as the preliminary process of storing the tubers in boxes made for the purpose may best be attended to about this time. Good results may be obtained from Potatoes that have not been put into the boxes until February or March—that is, four or six weeks before the planting operation was due. But, while spring boxing may be successfully resorted to in cases of emergency, it is generally conceded that the better plan is to store the Potatoes in the boxes throughout the winter. Let alone the relative effects of winter or spring boxing upon the subsequent crop, there are other sufficient reasons for giving preference to autumn or winter boxing. In the first place, there is usually more time for the performance of work of this description in the fall than in the spring of the year, while, in the second, there is no way in which the seed Potatoes can be kept more safely, or stored in smaller compass, than in the boxes utilised for the preliminary sprouting of the tubers. A third, and very important, advantage is that the Potatoes can be examined and overhauled at convenience, should that be found necessary, and, moreover, the process of sprouting can be regulated to a nicety by placing the boxes in a high temperature or a low, and exposing the Potatoes to light and air, or shielding them from the latter, as circumstances may require.

The size of box recommended by the Board of Agriculture for general use is, length 24 inches, width 12 inches, and depth 3 inches. The corner pieces are 7 inches in height, and sufficiently strong for the boxes to rest one on the top of the other when piled for winter storage. The handle-bar is made strong and tenoned into the end pieces, the whole forming a light, handy, yet durable utensil, which, with ordinary care, will last for years. The boxes are not expensive, the cost varying from 30s. to 35s. per hundred, and each box holds about 20 lb. of Potatoes, or six boxes will hold about 100 lb. The filling of the boxes involves no particular care or trouble. The boxes are filled until level with the sides, and neither earth nor water is added, and it matters not whether the eyes are upwards or not. If the Potatoes are large they may be only one deep in the boxes, but the ordinary seed size may be two or three deep, but this is no obstacle, as the sprouts find their way through the inter-spaces. When once filled, the boxes may be piled up one on the other to any height that may be found convenient. The sprouts should be about 2 inches long at the time of planting, and the management of the boxes should be directed with a view to this length of sprout being developed as uniformly as possible. There is no real objection to longer sprouts, except that they are apt to get broken off in the planting, unless very tenderly handled. As a rule, the sprouts are apt to exceed rather than fall short of the desired length, and the best way to check growth is to expose the boxes to light and air. If, however, it is found necessary that the sprouting process should be stimulated, the best plan is to exclude all light.

Apart from the effect upon the length of the sprout, exposure to light and air for some time before planting is necessary, in order to toughen the sprout and enable it to be hauled. A few days' exposure will suffice to make the sprouts quite tough and less liable to break, and this is an important consideration in averting accident

in the process of planting. In storing the boxes it is necessary that they should be placed where they are not liable to damage from frost. On the other hand, if they are stored in too warm a temperature, sprouting will be too rapid and vigorous. It is not unusual to pile the boxes on the rafters of stables and cow-sheds, where they are perfectly safe against frost, but may possibly suffer from excessive growth. As a rule, they will do very well in barns or sheds, provided they are protected from cold winds and covered over with straw or sacks when frost is severe and protracted.

It is impossible to say what quantity of seed is required to plant an acre, as the space required between the drills varies from 15 inches to 20 inches for early varieties and 24 inches to 30 inches for the strong-growing varieties. The sets may be planted from 8 inches to 12 inches apart for the early sorts, while for the late and vigorous-growing sorts a distance of from 12 inches to 18 inches must be allowed.

If any further information is required we shall be pleased to help you.

NOTES AND REPLIES.

Potatoes: Seed for 1917.—There has never been a time, perhaps, when more interest has been shown in Potato-growing than during the season which is just closing. The war has been responsible for many things, and one has seen throughout the country land that, to a large extent, has been lying idle for years now turned to good account. Some of this waste land was not procurable until late in the spring, and possibly has not yielded so profitably as it might have done had possession been taken last autumn. All this may now be rectified during the winter by digging the ground up roughly. I have before me a letter from a Potato grower in which he advises his customers who can do so to purchase their seed this autumn, and suggests it being kept in trays or boxes in some cool, dry place. A good many whom I know propose to act upon this advice, inasmuch as it is quite likely that all seed will be dearer next spring, through shortage of crops, and, further, one is more likely to have the best by giving the order this side of Christmas. It is well known that comparatively few orders reach the dealers until the New Year has set in, consequently, the first orders receive the best attention, finer seed is the result, and better crops are gathered. Some who read this note may be tempted to plant home-saved seed. At the outset it may seem economy to do so, but in practice it is not always so. A change of seed from one's own district is most desirable, and I am convinced it pays in the long-run. May I, therefore, suggest to all who intend to grow this indispensable vegetable another year to send orders for seed early, to grow sorts that they have proved are best for their locality, and to give plenty of room between the rows unhampered by winter greens, where late sorts are grown. There is nothing whatever gained by planting "greenstuff" between late Potatoes; on the contrary, it robs the ground and reduces the output.—LEAHURST.

Improving heavy soils.—The war is answerable for much. It is due to this that people, who before scarcely ever handled a spade, have, owing to the high prices charged for vegetables, set out to grow their own, and much land hitherto undeveloped has been turned to good account. In some cases it was not possible for ground to be rented until very late in spring, consequently its preparation was not so thorough as might have been. This can now be put right. Heavy land may be turned up and with it road-sweepings incorporated, and clods of clay can be reduced to a more workable condition by adding lime this winter.—W. F. D.

THE WEEK'S WORK.

OPEN-AIR GARDENING.

IN BLOOM NOVEMBER 29TH.—*Veronicas* (in variety), *Escallonia montevidensis*, *Jasminum nudiflorum*, *Laurustinus*, *Arbutus*, *Pampas Grasses*, *Rosmarinus prostrata*, *Polygala Chamæbuxus lutea*, *P. C. purpurea*, *Lithospermum prostratum*, *Parochetus communis*, *Aubrietias*, *Double Arabis*, *Tufted Pansies*, *Lobelia cardinalis*, *Petasites fragrans* (Winter Heliotrope), *Iris stylosa*, *Erica carnea*, *E. mediterranea hybrida*, *Sternbergia lutea*, *Violets*, *Roses*, *Clematis*.

THE WEEK'S WORK.—Choice trees and shrubs are being top-dressed with suitable compost, as far as circumstances will allow. I prefer to thoroughly dress a few trees each year rather than distribute the available material in small quantities over the roots of many trees. If the trees to be top-dressed are on turf, the turf is rolled back, the surface-soil lightly loosened with a fork, and the dressing applied. The turf is then replaced, but not beaten down, only levelled, thus the trees get the full benefit of all the rain that falls. Garden hedges usually receive plenty of attention in pruning, but are often neglected at the roots. It should be borne in mind that hedges (especially of Holly and Yew) exhaust the soil, and when this happens the plants become weak, and branches die, leaving unsightly gaps. Surface dressings are essential to preserve old hedges in health and should be given as circumstances allow. When the weather is unfavourable for ordinary garden work, attention is paid to the shrubberies. Where these are thick and becoming overgrown, some of the common things are grubbed up to make room for choicer subjects. Here and there a complete clearance will be made on the margins. Such cleared spaces will be manured, dug deeply, and planted with Michaelmas Daisies, Delphiniums, and Pæonies in bold groups. Summer-leaving shrubs which from any cause were left unpruned just after flowering will be attended to at the same time. The majority of these bloom on wood of the previous year's growth, hence the pruning consists chiefly in thinning out tangled, weakly, and unripe wood, and shortening back soft and sappy growth, retaining only firm and well-ripened shoots, which will flower satisfactorily in their season. This thinning even thus late will be beneficial by admitting the maximum of light and air among the branches, this conducing to free flowering later. Those flowering on the current year's growth—for instance, *Buddleias*—should be hard pruned, using a sharp knife in preference to scateurs for this work. Any division and moving of herbaceous plants not yet completed should be carried out without delay. Grouping, whereby the varieties of a given species are kept together rather than mixed one with another, is much in favour, and if the scheme of arrangement is well defined beforehand, the ultimate effect is very pleasing. Christmas Roses are very useful for cutting in December and January, and in order to have the blooms as clean as possible frames are placed over the plants as soon as the flower-buds appear. These plants succeed best in a sheltered and semi-shady position in a rich, deep loam with which a fair quantity of leaf-mould is mixed. If frequent applications of liquid-manure are given the length of the flower-stems is considerably increased. F. W. GALLOP.

Lilford Hall, Oundle, Northants.

SOUTHERN COUNTIES.

Cucumbers.—To have good strong plants for setting out early in the New Year they should be raised at the present time. In a sharp heat the young plants grow quickly and by the time the house is made ready for them they will be of good size and eventually come into bearing long before those raised from a sowing made at the orthodox period—i.e., the first week in the New Year. There is no better method of sowing than to use small 60-sized pots, sowing one seed in each, the pots being filled with light, rich loamy compost. The raising can be carried out in a propagating-case or under a handlight or cloches. It

matters not which, so long as there is good top and bottom heat. Great care is required after the plants are up, as they must be kept from becoming drawn. A light position near the glass is essential, and in the absence of such a position a temporary shelf fixed over the hot-water pipes at the front of the house will answer the purpose for the time being. When ready for a shift, the balls should be placed low down in the pots to encourage the emission of roots from the stems. The compost should contain a good percentage of fibrous loam well pulled to pieces. More plants than are actually required should be raised so that none but vigorous examples need be used for setting out.

Late Grapes.—Particular care is needed in a season like the present, both to prevent the berries decaying on the one hand and the skins shrivelling on the other. To avoid the former calamity anything approaching a damp atmosphere must be guarded against—not only must the paths and border surfaces be kept dry, but a gentle heat maintained in the pipes also which will ensure a free circulation of air and prevent stagnation of the atmosphere. The admittance of air by the ventilators while outside conditions are so humid must be done with great care and only when the weather is fine and light. Shrivelling of the skins of the berries is generally thought not always due to the employment of too much fire heat. In such cases the remedy is obvious. The exception to this rule is when the borders are allowed to become unduly dry. Once this happens no amount of water will restore them to their normal condition, but matters can be prevented from going from bad to worse by affording just as much water as will stave off the evil until the time arrives for bottling the Grapes. The border in such a contingency should afterwards be covered with a good thickness of dry litter and an extra amount of fireheat employed for a few days to counteract the moisture, a certain amount of which, in spite of all precautions, will be given off from the border. When there are but a few bunches hanging in a vinery, it is then far more economical in every way to remove and bottle them. The vinery can then be freely aired and the Vines, if the leaves are down, pruned and afterwards cleaned as opportunity offers.

Grape-room.—Some time between now and the end of the year this should be got ready for the late-keeping Grapes. The removal of the bunches and the insertion of the pieces of laterals to which they are attached in the bottles can then, when the time arrives for doing so, be done expeditiously.

Fig-trees.—Both trees in pots and those planted out required for starting early should, after the structure has been cleaned down, be overhauled and cleansed. As far as the old wood is concerned, a good deal of pressure may be executed in the scrubbing and brushing of the bark, but, in regard to the younger or this season's wood the cleaning must be confined to the use of a soft brush only or the embryo fruits may be seriously injured. An approved insecticide mixed or diluted according to instructions should be used for cleansing, especially where scale has in previous seasons been troublesome. The forcing may be considerably expedited with regard to pot-trees if they can be given bottom-heat obtained either from hot-water pipes or by the more economical method of employing a bed made up of tree leaves of which an abundance is now to be had in all woodland districts. In this case something of a permanent nature is required to stand the pots upon, so that they do not move out of position as the fermenting bed subsides. The wood in permanently-planted trees should be pruned or thinned as far as is necessary, and then be refastened to the trellis. Fine, soft, tarred twine is better for this purpose than raffia, as the latter, seeing so much syringing is requisite throughout the growing season, soon rots away.

Outdoor Vines.—These should be pruned now and not left, as they often are, in an untidy condition through the winter, and then dealt with when the sap is on the rise, with the risk of much bleeding ensuing. If attended to at this time of year, bleeding will not follow. The spur wood should be cut back

to one or two buds on all established specimens. The young canes on more recently planted examples should be shortened to where the wood is firm and well ripened.

Outdoor Figs.—If not already done, the liberating of the branches from the wall, afterwards tying them in bundles so that they may be more conveniently have Bracken or straw worked between them and finally covered with mats, should be no longer delayed. In most parts of the country some amount of protection is required for Figs, as the embryo fruits are very susceptible to injury should severe and prolonged frost occur.

Tender shrubs.—Myrtles, scented Verbenas, and anything of a tender nature should be covered up for the winter in localities where it is not prudent to leave them unprotected. Straw or Bracken, with mats to hold it in place, are the best protective materials to employ for this purpose. A. W.

MIDLAND COUNTIES.

The early vinery will now be started. A temperature of 45 degs. to 50 degs. will be maintained till the Vines show signs of breaking, when it will be raised 5 degs. As mealy-bug was detected on the Vines in this house in the autumn, the rods will not be tied up permanently until they have had another good washing. This will be done just when the buds are breaking, taking care not to damage the young growths. As growth proceeds the temperature will be gradually increased. All outside vinery borders have been given a mulch of rough stable manure 4 inches to 6 inches thick. This will protect the roots from severe frost. Where Vines have been showing a tendency towards weakness of growth a rich mulch should be applied to outside borders, which will benefit the Vines through the carrying down of the ammonia and nitrogenous food materials by the rains.

Fruit-tree pests.—Fruit-trees and shrubs are subject to the attacks of many pests during the spring and summer months. The present is the best time in the whole year to do battle with these pests, as more drastic measures can be employed while the trees are leafless and dormant. Scale insects are often found on Peach, Apple, and Pear trees. The ordinary brown scale attacking the Peach-trees can easily be dislodged with a small label, but the Mussel-scale, that clings so tenaciously to Apple and Pear-trees, requires more drastic treatment. Trees, especially Pear-trees, growing against walls are generally most affected. In bad cases the bark should be scraped with a flat piece of wood or a piece of hoop-iron, and afterwards brushed with a hard scrubbing-brush, eventually thoroughly spraying with caustic soda wash, which should be applied this month to all Apple, Pear, and Plum trees subject to the attack of insect pests. These winter sprays are best applied by a knapsack sprayer, but in the case of a small garden a hand syringe with a suitable spraying nozzle attached does equally well. Care should be taken that every part of the tree is wetted. Badly-infested trees may in some cases need a second application at the beginning of the year before the buds begin to swell.

Gooseberry and Currant bushes that have been badly attacked by caterpillars should, after the pruning is completed, have all the surface-soil about them removed to a depth of 3 inches or 4 inches, replacing with fresh compost. When this is done, apply a good dressing of freshly-slaked lime, also dust the trees with a mixture of soot and lime to prevent the birds destroying the buds. Lime is an excellent material for destroying pests of all kinds that attack fruit-trees.

Violets in frames are flowering well. Any attempt to coddle these plants will be sure to result in weakly crowns and a poor supply of flowers. The lights may be shut down on cold and stormy nights, but do not cover the frames unless more than 5 degs. of frost are anticipated. On all other occasions ample ventilation should be afforded, remembering that a close atmosphere causes the foliage to damp off. Unless the plants are growing in

heated frames, water will be rarely necessary until the New Year. Should the roots need moisture, let it be applied on a mild morning, so that the plants may be left fully exposed for the remainder of the day. By this means the excessive surface moisture will evaporate before night. All decaying leaves should be picked off, and the surface-soil lightly pricked up occasionally.

Rosette Coleworts are most useful at this time, and the plants are well hearted. Unfortunately, they are not perfectly hardy, so that the crop should be used as quickly as possible, meanwhile saving the Brussels Sprouts, which they somewhat resemble in flavour.

Scotch Kale is also a delicious vegetable now that the cold has rendered it tender. The plants will furnish a very large amount of green food if gathered very carefully. As in the case of Brussels Sprouts, the heads should not be cut, but only single leaves gathered, a few off each plant at a time. In spring the heads may be cut, and the plants will then develop a large crop of side shoots. Winter varieties of

Broccoli are now turning in. At no season does this crop need more attention than now, and all plants that are hearting need to be examined at short intervals, and the heads cut when sufficiently large. The curds are usually small, but of first-rate quality. There is a danger of them being damaged and rendered useless by wet or frost if left to gain in size.

Potatoes.—The sets intended for early forcing will now be selected and laid out thinly on suitable trays, on which has been placed a little finely-sifted manure from a spent Mushroom-bed. Moderate-sized tubers of such varieties as May Queen, Sharpe's Victor, and Sharpe's Express are chosen. These make little haulm, and are quick to mature. The tubers will be placed in a light position in a temperature of about 50 degs. to sprout. The earliest crops may be grown in pots and boxes in vineries and Peach-houses, but, as tree leaves and stable litter are to be had in abundance, we rely entirely on hotbeds for their production.

Roots in the store, especially such as Potatoes, Onions, Shallots, Garlic, Beetroot, and Carrots, need to be frequently and carefully examined.

Mint roots placed in heat a month ago are furnishing young, green shoots. A continuous supply may be had by placing the roots closely together on a bed of leaves. Tarragon and Chives may be forced in the same way, lightly covering the roots with sifted leaf-mould. Up to the present

Preparing of the ground for next year's crops has made satisfactory progress, but the weather during the past week has not been favourable for trenching and digging. Full advantage is taken of frosty mornings to wheel manure, etc., on to vacant plots. By this means sufficient can sometimes be wheeled on to last for several days' digging or trenching, and the walks are not so much cut up. A fire is kept going to burn all garden refuse, and the accumulation of ashes will be valuable for putting on the ground.

F. W. GALLOP.

SCOTLAND.

Dahlias.—Even at this late date Dahlias have not been frosted over; but, as they were untidy, they were in the course of the week cut over and lifted. After being partly dried at the foot of a wall for a day or two, the roots were stored. A cool, dry, frost-proof place, such a place, in fact, as suits Potatoes, will be found satisfactory for storing the Dahlias. Care, of course, in labelling the different varieties securely is necessary, for nothing is more irritating than to find when propagating time comes round that the labels have been carelessly attached to the stems and have fallen off in the course of the winter.

Salvia patens.—At the same time, the roots of this were lifted and stored in a similar way. This Salvia is deservedly a favourite, and a good number of roots was stored. This will not, however, prevent a batch of seedlings being raised in the spring, for I always think that seedlings ultimately make better plants

than those from cuttings, although they are later in coming into bloom.

Gladioli, too, have been attended to. These are largely grown. In the meantime the corms are lifted with the foliage attached and tied up in bundles according to variety. Later on, when the leaves are quite dry the corms will be cleaned, graded, and laid out on shelves in the store-room.

Hardy Chrysanthemums.—Even in the comparatively mild winters experienced in this district it is not safe to rely upon hardy Chrysanthemums coming through without loss. Damp, I think, is more dangerous than frost; while young growths fall a ready prey to slugs. Therefore, a two-sash cold-frame is packed with stools of the required varieties. These, being put out in a prepared bed of rather light, sandy soil, winter exceptionally well, and provide large quantities of sturdy cuttings.

Hardy flower borders.—A beginning was made during the week with the cutting over and cleaning of the hardy flower borders. First of all, the stakes are taken out, sized, and tied in bundles, those which are of no further use being put apart. During the present season, instead of, as formerly, wheeling the refuse to the rot-heap, it is being taken to a convenient brake upon which it will—along with other rubbish—be burned during frosty weather. There is a small percentage of potash in these stems, which, even if trifling, will be of benefit to the soil upon which the rubbish is burned. After cutting over is completed, a light touch-up with steel rakes is given to the borders, which keeps them tidy until forking time.

Pruning in the case of wall trees will, as was previously indicated, be delayed yet awhile. The foliage is hanging much later than usual—later, in fact, than has been the case since 1903, when the Peach-trees remained green until after the New Year. In the open, however, more especially in the case of young Apple-trees, the leaves are now rapidly falling, and pruning will, therefore, be undertaken shortly. During the week a finish was made with the pruning of Red Currants, and a good beginning made in the case of Gooseberries. It always pays to keep the centres of the bushes open, and to remove unprofitable wood. If large berries are wanted, it ought to be remembered that young wood gives the finest fruit; but if the crop be chiefly required for using in a green state, for bottling, or for preserving, fairly close spurring can be resorted to, with, of course, sufficient extension of the terminals in the case of young bushes. Gooseberries are gross feeders, and will assimilate cruder manure than other things; but I think it is better given as a mulch. No matter how carefully manure may be dug in, there is always the risk of danger to the roots, and where these are injured there is sure to be a plague of suckers. Where caterpillar is known, or suspected, to exist, the customary precautions ought not at this time to be omitted.

Stove.—With the lessening attractions of the garden, glass-houses come in for more notice, and an effort must be made to keep them as bright as possible. At the present time there is no difficulty in that respect so far as the stove is concerned. Hymenocallis spikes yet remain in good order, Pentas rosea and Libonia floribunda, if not the most showy, are yet useful. The winter-flowering Begonias are, of course, always a stand-by, and Gesneras are useful in various ways. Cypripediums are useful, the blooms lasting very well when used as cut flowers. It is seldom, indeed, that Thunbergia laurifolia is without bloom, and the use of brightly-coloured foliage is effective during winter. Small pieces in 4-inch pots of Acalyphas, Pandanus, and Dracenas are easily raised, and are useful in a variety of ways. Now that the nights are colder the fire ought not to be driven. A morning temperature in the neighbourhood of 60 degs. is ample. Syringing may, if preferred, be dispensed with meantime, the necessary moisture being obtained by damping the paths.

Cool-house.—Such things as Schizanthus, Primula malacoides, Coleus thrysoidens for spring flowering, Begonia Weltoniensis, B.

fuchsioïdes, Calceolarias, and similar things should not at this season be over-watered. At the same time regular inspection is necessary, plants in the neighbourhood of hot-water pipes naturally drying up more quickly than others. On all suitable occasions let the ventilation be free, but avoid admitting cutting winds.

Greenhouses.—Chrysanthemums are yet, and will be for some time, the leading feature of greenhouses and conservatories. To prolong the display give only sufficient water to keep the plants in good order, and dispense with all unnecessary washing down of floors or of paths. *Salvia splendens*, *S. lactiflora*, *S. Pride of Zurich*, and *S. rutilans* are showy. So, too, are *Eupatoriums*, while the earlier batches of *Primula sinensis* and *P. obconica* are coming into bloom. The first batch of *Cineraria stellata* is showing colour, and, altogether, the display is bright during the short days.

Ferns under glass.—Let these have all the light possible, and if any shading yet remains on the glass, let it be at once washed off. A moderate amount of heat and of atmospheric moisture, with occasional allowances of weak stimulants, will go far toward keeping Ferns in good condition during the short, dull days.

W. MCGUFFOG.

Balmæ Gardens, Kirkcudbright.

CORRESPONDENCE.

Questions.—Queries and answers are inserted in GARDENING free of charge if correspondents follow these rules: All communications should be clearly written on one side of the paper only, and addressed to the EDITOR of GARDENING, 63, Lincoln's Inn Fields, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent each should be on a separate piece of paper, the name and address being added to each. As GARDENING has to be sent to press some days in advance of date, queries cannot always be replied to in the issue immediately following their receipt. We do not reply to queries by post.

Naming plants.—All who wish their plants to be rightly named should send fair examples of each—the stem, leaf, flower, or fruit. (Snippets of leaves and points of shoots are useless.) Not more than four plants should be sent in any one week by the same correspondent. Where more than one kind is sent they should be numbered. Of conifers the fruit should always be sent.

Naming fruit.—Several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruits for naming, these in many cases being unripe and otherwise poor. We can undertake to name only four varieties at a time.

PLANTS AND FLOWERS.

Romneya Coulteri (R.)—Instead of cutting your plant right down it would have been far better to have removed some of the old shoots and protected the younger wood, putting a mulch over the roots. By cutting it down now there is the danger of the plant starting into growth, which will be injured should the winter be very severe. The best way to secure strong growth is to cut the plant down every spring, and in this way encourage the formation of shoots from the base.

Potting Calceolarias (Anon.)—Sizes of pots for plants must be governed by the dimensions of the plants. Thus seedling *Cinerarias* and *Calceolarias*, if now in small or 3-inch pots, may be shifted into 5-inch pots and remain in them for two months, by which time they should be well rooted; then they may be shifted into 7-inch pots, which will be, as a rule, quite large enough to enable them to bloom well in. It is so much the rule with these plants to overpot, and thus cause them to produce excessive leaf-growth rather than good heads of bloom. Over-potting also usually causes the soil to be too wet, and become

sour, to the injury of the roots. Both descriptions of plants like a gentle syringing occasionally, but in damp weather there is no need for it. Very weak manure-water may be used once a week, after the pots are filled with roots.

FRUIT.

Fruit-trees for south wall (Ignoramus).—On the wall facing south you can grow either Peaches, Nectarines, Apricots, Cherries, or Plums. You do not give the length of the wall, so we give you the names of three varieties of each from which you can make your own selection. Peaches: Duke of York, Crimson Galande, Stirling Castle. Nectarines: Early Rivers, Lord Napier, Elruge. Apricots: Moorpark, Kaisha, Hems Kirk. Cherries: Early Rivers, Elton, Bigarreau Napoleon. Plums: Denniston's Superb, Jefferson, Coe's Golden Drop.

Mildew on Grapes (A. S.)—We have seldom seen Grapes so badly attacked by mildew, plainly showing that the cultivation is at fault. We should advise you to at once cut off all the bunches and burn them, and dust flowers of sulphur all over the Vines, washing this off after a few days with clear rain-water. In the winter all the inside wood-work should be thoroughly cleaned and repainted, and if there is a back wall have this lime-washed. Then dissolve $\frac{1}{2}$ oz. of sulphide of potassium in a quart of water, mix it with clay and sulphur to a thin paste, and brush this into the bark and every crevice about the spurs on the Vinerods, applying this dressing immediately you see any further signs of mildew.

Limewash on fruit-trees (J. F.)—When limewash or wash is put on to tree-stems in a hot state it adheres for a long time. It looks much less objectionable if some clay be mixed with it to render it less conspicuous. We prefer that it should not so long adhere, but if put on in the winter to kill Moss and insect pests, which is the primary object in view, it should peel off in the spring, so that the bark might be more free to effect its ordinary functions. A good mixture for thus coating trees is 10 lb. of fresh lime, gradually dissolved in a tub, 6 lb. of soft soap, dissolved in boiling water in a large pail, and added to the lime-water, and some soot or clay, or both, added, and enough water to make into a pasty wash.

Pot Strawberries (H. F.)—It would have been better for your Strawberry plants, now in small pots, had they been shifted into 6-inch pots not later than the middle of August. When layered into small pots, Strawberry runners soon fill the pots with roots, and if not shifted into others speedily, soon become stunted or starved, so that time is lost. Had they been so potted then, the larger pots would now have been full of roots and the plants and crowns much stronger. However, if you shift your plants at once into 6-inch pots, use good turfy loam with which are mixed a little soot, bone-dust, if you have it, and at the rate of about one-sixth of old-decayed manure. Pot very firmly, as hard soil is best. Stand the plants in a cold-frame near the glass for the winter, giving plenty of air, and do not attempt to force them, and then gently, until April next, by which time they should have rooted.

Treatment of old Apple-tree (Ignoramus).—To restore the tree in question to a fertile condition you should have whatever pruning it may require performed at once by a practical man, whom, doubtless, you can obtain the aid of in your neighbourhood, and then give the roots a good dressing of well-rotted manure. This should be evenly spread beneath the tree to as far as the branches extend in all directions, after having removed the soil some 5 inches to 6 inches in depth. The soil should be afterwards spread over the manure and lightly trodden down. If a number of roots are met with at a less depth than that stated when taking out the soil, you must then desist, but if roots are not found at a depth of 6 inches you may safely bury the manure another 3 inches deeper than this. Before spreading the manure, lightly prick up the soil between the roots with a fork. The coating of manure may be 4 inches to 5 inches deep. When sending again, please observe our rule as to writing queries on one side of the paper only.

VEGETABLES.

Seed Potatoes (G. J.)—If your seed Potatoes in a clamp are kept cool and dormant they are just as safe there as anywhere else. But the winter is so far mild, and for that reason we should prefer to keep them on dry shelves, where they would be exposed to light and air, and thus kept dormant. Shallow boxes are capital things to store Potatoes in, and if not large to carry them in to plant.

Lifting roots (Scraper).—If you scan recent numbers you will find that instructions were given as to lifting the root crops you refer to. Beet-root, Parsnips, and Onions ought to have all been stored several weeks ago, and instructions as to doing this appeared in the "Week's Work." Harvest the Onions and Shallots at once, have them carefully dried and put into store. The Chinese Artichokes you may leave in the soil, throwing some litter over them so that you can dig any up when wanted, or you may lift the whole crop and select good tubers for planting in the spring, and store the remainder as you do Potatoes.

SHORT REPLIES.

Arch. Alison.—The selection you give is a very good one, and we should advise that you procure trees on the Paradise and treat them as you suggest. The soil is very suitable. At the same time it would be well to find out what varieties are a success in your district, as the behaviour of Apples varies so in different parts of the country.

NAMES OF PLANTS AND FRUITS.

Names of fruits.—*J. G.*—Apples: 1, Stone's Apple; 2, King of the Pippins; 3, Sturmer; 4, Leathercoat Russett.—*E. C.*—Apples: 1, London or Five Crowned Pippin; 2, King of the Pippins; 3, Small Blenheim; 4, Golden Noble.—*D. W. W.*—Apples: 1, Lane's Prince Albert; 2, Warner's King; 3, Norfolk Beaufin; 4, Lord Burghley.—*J. Ross.*—Pears: 1, Doyenné du Comice; 2, Glou Morceau; 3, Thompson's.—*W. W.*—Apples: 1, French Crab; 2, Ribston. Pears: 3, Nouvelle Fulvie; 4, Verulam, a stewing variety.—*A. R. S.*—Apples: 1, Blenheim; 2, Wellington.—*T. C.*—Apples: 1, Wellington; 2, Yorkshire Greening; 3, Ribston Pippin.—*J. T.*—Apples: 1, Cellini; 2, Crimson Queening; 3, Ecklinville; 4, Norfolk Beaufin.—*M. S.*—Apples: 1, Winter Hawthornden; 2, Golden Noble; 3, Cox's Orange. Pear: 4, Brown Beurré.—*L. M. S.*—Apples: 1, Blenheim; 2, Annie Elizabeth; 3, Alfriston; 4, Lane's Prince Albert.—*H. G. B. H.*—Apples: 1, Brabant Bellefleur; 2, Probably Rymer; 3, King of the Pippins; 4, Evidently a local variety. When sending fruit for name, at least three specimens should always be sent, as the fruits vary so.

CATALOGUES RECEIVED.

Royal Horticultural Society's meetings.

—The future fortnightly meetings of the Royal Horticultural Society will close at 4.30 p.m. instead of 5, as announced in the "Book of Arrangements" and Fellows' tickets, to enable compliance with the lighting regulations.—W. WILKS, Secretary.

The Royal Horticultural Society's Daffodil Show.

—The schedule of the Royal Horticultural Society's Daffodil Show to be held on April 17th, 1917, is now ready and can be obtained by a letter of application, accompanied by an addressed foolscap envelope stamped with a penny stamp, to the Secretary, R.H.S., Vincent Square, Westminster, London, S.W.—W. WILKS, Secretary.

CLEANSER VIM & POLISHER

VIM IS EVER READY.
It is always the same, always the best and brightest of cleansers and polishers.

THE big guns of the kitchen defend its great reputation. Good cooks praise it; clean cooks always use it.

It is splendid for cooking utensils of every kind; for iron pots, enamel pots, copper kettles, tin kettles, frying pans and casseroles. Use it for keeping the pastry board, table top, dresser and paintwork of the kitchen clean and wholesome.

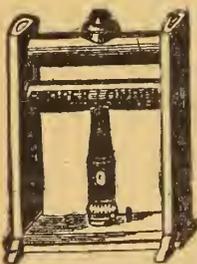

THE BIG GUNS OF THE KITCHEN DEFEND THE BIG REPUTATION OF VIM THE GREAT CLEANSER & POLISHER.

In 6d., 3d. & 1d. Sprinkler-Top Tins.

LEVER BROTHERS LIMITED, PORT SUNLIGHT. V 110-11

COOPER'S HYGIENIC HEATER.

Our Own Manufacture.
Suitable for Greenhouses, Offices, Living Rooms, etc.

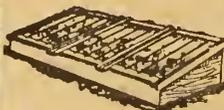

For burning paraffin Oil or Gas without smoke or smell. These stoves give off neither smoke nor smell, and will keep a Greenhouse from 15° to 40° above outside temperature. Portable and complete. Nothing to break. Fitted with iron chimneys. These Heaters are constructed as a means of heating by hot air without the use of Hot water or Fires. Its construction economises the heat generated, so that there is no waste of Heat or fuel. There being perfect combustion in this Stove and nothing whatever injurious to plants, but actually everything conducive

to their health, it should be observed that plants may be had in full bloom throughout the severest winter. This cannot be obtained in stoves of other systems. The temperature can be regulated to a nicety to all requirements, being raised 15° to 40° above that of the outside. To heat space 7ft. by 5ft., 21s.; 9ft. by 6ft., 30s.; 12ft. by 8ft., 50s.; 15ft. by 9ft., 65s.

CLEMATIS—A NEW HYBRID.

SUPERLATIVELY interesting it would be to find a savant given to the pathological study of plants who would undertake the study of the Clematis disease. But the Clematises, producing neither bread nor wine, do not interest a sufficiently large part of humanity, so that the savants would lose their time in occupying themselves with their diseases. However, man does not live by bread alone, and the sight of a fine Clematis in flower gives as much, if not more, pleasure than a good meal. I have just seen in flower—and, more, I have enjoyed for the first time the fragrance of—a pretty Clematis obtained by crossing *C. tubulosa* and *C. heracleifolia*. You are aware that *C. heracleifolia*, blooming in September and October, has small gray-blue flowers insignificant enough to look at, but which exhale the delicious fragrance of Orange Flower. At the same time *C. tubulosa* (*C. Davidiana* according to some authors) shows its fine flowers arranged on axillary verticils along its leaf-stems. By hybridising these two kinds I have obtained a hardy plant with beautiful blue flowers standing out in clusters against the background of foliage and exhaling the fragrance of *C. heracleifolia*. I imagine that strong tufts of this new Clematis would win the lively appreciation of lovers of hardy plants by reason of the beauty of the flowers, and especially their fragrance, at a time of the year so devoid of flowers as is the month of October. As an example of magnificent flowering at this season I have just witnessed that of *C. paniculata*, a giant form of *C. Flammula*, of the south of France and Europe. I have had it photographed.

Lyons. F. M.

NOTES OF THE WEEK.

Convolvulus Cneorum.—This is flowering in General Gough's garden near Conway, and any quantity of buds is ready to open. Flowers were open at the end of November. Wild Primroses are in flower here.—E. CHARLES BUXTON, *Coed Derw, Bettws-y-Coed.*

Carnation Nancy.—This is one of the pink-flowered set, the colour of an exquisite shade of soft salmon, that degree of it which was so largely responsible for the popularity of the old Miss Jolliffe. In this respect the newcomer is very much alone, even amid the wealth of pink-flowered Carnations as we know them to-day. The flower is flattish in form as opposed to the

rosette character of some, and in this is rather suggestive of America, one of the earliest of the American perpetual-flowering set to gain recognition in this country. Nancy pleases by reason of delicate beauty and refinement. Messrs. Allwood Brothers have been showing it well.—E. H. JENKINS.

Ceratostigma plumbaginoides.—The dull, wet season must be responsible for the poor flowering of this usually lovely subject, I think, as though there was a good show of buds, I hardly had any bloom worth speaking of on several patches growing on a wall. Nor did the leaves take on anything like their usual brilliant autumn hues.—N. L.

Erica hybrida.—As in a number of other years, this is not going to be appreciably earlier than the varieties of *E. carnea*. In some seasons it blooms well in November, but in others it lingers until the beginning of the New Year. It is full of flower-buds this winter, but the blooms will not open before January, or will not, at least, show their proper colouring. Probably the wet autumn and early winter we have experienced are the reasons for this delay.—S. ARNOTT.

Late Meadow Saffrons.—The wet and stormy weather we have had in this district has spoiled the Meadow Saffrons. Today (December 4th) I see some flowers still on *Colchicum autumnale roseum plenum*, the latest of the double Meadow Saffrons with me, and also on a clump of *Colchicum autumnale*. The bit of colour is very acceptable at this time. Up to November 30th the rainfall recorded at one station in the district was about 8 inches above that of the corresponding eleven months of 1915.—S. ARNOTT.

The wild Clematis.—I do not understand "A. T. J.," p. 602. Does he mean to say that I have glorified the wild Clematis as a stock or in any other way? The reverse is the case, as he or any other reader may see by referring to my previous notes. I did not say that this Clematis is never found growing on loam. I distinctly said that in this district it is only to be found on the chalk, that in spite of the multitude of seeds ripened it never seemed to extend, and over an area of many square miles where the subsoil is gravel or clay I had never seen one single plant. The wild Clematis is not a plant for the garden. It is far too aggressive.

Notes from Ashbourne.—*Clerodendron Fargesii* is a remarkable shrub. The flowers are somewhat insignificant, but the fruit is both singular and striking—a persistent calyx of dull purple in the centre of which is placed a turquoise-blue circular

fruit. Whorls of these fruits cover the shrub, even after the leaves have fallen, and the effect, especially in sunlight, is beautiful. It is a sun-loving plant and prefers light, poor soil. It has been good weather for moving the various trees and shrubs. All my colour shrubs are being gradually re-established upon hot, poor banks, and will probably turn all the better in the autumn. It is a mistake to plant them in rich soil, because they are rare or uncommon, and yet we often make this mistake, with consequent loss of natural colour.—RICH. H. BEAMISH.

Crocus longiflorus Mr. Bowles' Pale Seedling.—This is in bloom to-day (December 4th) and has been open for a week or two. It is pleasant to have such a Crocus in flower in the open—and that without any protection—so late in the year. This variety was raised by Mr. E. A. Bowles, and the title gives an adequate description of its colouring, which is paler than that of the ordinary *C. longiflorus*, one of our best autumnal and early winter-flowering species.—S. ARNOTT.

The Fraxinella (Dictamnus Fraxinella).—I well remember having seen some plants of this in full bloom in St. John's College Garden, Oxford, last June. The white *Dictamnus* was also grown, but I did not care for it quite so much as the other. The plants bore some really grand spikes, and would remain in bloom, I was told, for some time. This plant, which does best in a light soil, is increased by seeds sown as soon as they are ripe, or by its fleshy roots, which, if cut into pieces, will in spring form good plants much more quickly than seedlings.—E. T. ELLIS, *Sheffield.*

The Lemon Grass perfume.—I was interested in the note concerning the Lemon Grass in the issue of December 2nd (p. 604). I have previously referred to this delicately-perfumed plant in these columns, and although it is by no means showy, it is useful in the stove. The plant grows almost 3 feet in height, with minutely-serrated dark green foliage almost a yard in length. It is readily increased by division, and may be planted out during the summer months. It needs, however, stove heat during winter. Occasionally it blooms, the inflorescences resembling, to some extent, those of *Humea elegans*, while the perfume is almost identical with that of *Aloysia citriodora*.—W. MCGUFFOG, *Balmoe.*

Sericographis Chiesbreghtiana.—Several well-flowered examples of this old-time winter-flowering greenhouse plant in an exhibit of Begonias from Earl Browlow

FRUIT.

APPLE ALLINGTON PIPPIN.

recently reminded one of many others contemporary with it now rarely seen. Hoveas and Rogieras are among those which occur to one, though an old catalogue would recall many more. That above named, which is now included under Jacobinia, was at one time indispensable among greenhouse flowering subjects, and, because of the profusion of its crimson-scarlet flowers, was grown in some quantity. Easy to grow and propagate, it was, nevertheless, impatient of an excess of moisture at the root, thrips and red spider being a common plague. Those exhibited were very clean and well grown, and we were pleased to know that the plant still finds favour because of an elegant habit and freedom of flowering. It is, of course, entirely outclassed by the modern race of winter-flowering Begonias so well shown from the same gardens, albeit the plant associates uncommonly well with the best of these, while adding diversity both of form and colouring.—E. H. JENKINS.

Eccremocarpos scaber.—This sub-shrubby climber is very suitable for a sunny position against a trellis or wall in the midland and southern counties. Belonging to the Bignonia family, it produces slender stems 12 feet or more long. The tubular flowers are each an inch long and borne in racemes up to 6 inches in length, the colour orange and red. Seeds are produced in quantity, which soon vegetate and form good plants. As a rule, only the lower portion remains alive. A little mound of cinders placed about the base of the stem in winter helps to protect it.—D.

The soil at Kew.—A reader having raised the question as to the nature of the soil at Kew, led us to ask the question:—

"The soil at Kew varies. By far the greater part is a shallow, sandy soil overlying pure sand or gravel. In many parts this top layer of soil is only about 6 inches deep, but stretching from the Thames to the pond near the Palm-house is a belt of good loam averaging 100 yards in width. In some parts this is clayey.

"At the north end of the gardens are the sites of several old kitchen gardens. This is a light but dark soil, and is, I suppose, the ordinary sandy soil to which humus was added. That is about seventy or eighty years ago. We should say at least three parts is the poor, hot, sandy soil.—W. J. B."

Saxifraga Fortunei.—One of the surprises of the autumn of the present year was the early and complete manner in which this pretty Japanese kind succumbed to frost before it had fully reached the height of its beauty. Of the little set to which it belongs *S. cuscuteformis* is, perhaps, the least hardy, and not for several years past do I recall that above named so irretrievably ruined. This, of course, may be due to many things—the drier conditions of the moment, frost of less severity, and suchlike. To some extent, also, it may be due to a more vigorous, succulent growth, the direct result of a rather generous system of cultivation, which is also responsible for that more attractive flowering desired by the gardener. All the same, seeing that it comes late in the year, and in leaf and stem colour and elegant blossoming makes one of the prettiest of pictures in the rock garden, it would be worth while in any fresh plantings to reserve some at least for a position where the morning sun does not early reach the plants. Failing this, a little protection—the spreading sprays of Yew or like shrub—might be helpful should severe frost threaten when it is in full plumage. In northern gardens the plant is not reliably hardy out of doors.—E. H. JENKINS.

ALLINGTON PIPPIN does not succeed on "W.'s" soil, does not please his palate; therefore it is a failure! In the comparatively few years since its introduction this Apple has been planted by thousands by those who either approved of its flavour or valued its good cropping qualities. In two recent Apple elections it found its place among the first half-dozen. The main reason that Allington Pippin was introduced was that it is a better cropper than any of "W.'s" list, and cropping is, after all, a matter of some importance. To recommend D'Arcy Spice to be generally grown is to betray a lamentable ignorance of its behaviour on most soils, and will only lead to disappointment. That the trade should be more careful in their introductions is undoubtedly necessary in some cases, but even writers to horticultural journals might pause before recommending fruits which will fail in nine gardens out of ten. The withholding of certificates until the fruit is thoroughly tested is sound, and on this point there will be no two opinions. E. A. BUNYARD.

[I have known the D'Arcy Apple much longer than Mr. Bunyard, and have seen trees in Essex bearing very well. I doubt if it has been as fully tried as it deserves on various stocks to see which suits it best. As to cropping, hundreds of kinds of Apples in every country crop well, many of them far too well, and this is no proof of quality.—W.]

—On page 606 "W." refers to the unsatisfactory quality of Allington Pippin, and I agree with him, in spite of the fact that, owing to its appearance and good cropping, it is in favour with market growers. Many of the public like it, but then, they have not access to better sorts as a standard of comparison. King of the Pippins, one of its parents, does not in the least appeal to my taste, yet it is a great market Apple. The raisers of several of these new varieties think that if they take Cox's Orange as one parent and almost any Apple for the other they are likely to get a good fruit. The result, as a rule, is a good-looking Apple, but the quality very inferior. Nearly all the Apples raised by Mr. Charles Ross as the result of crossing Cox's Orange with Peasgood's Nonsuch are very disappointing in quality. Very little has really been done to cross varieties with a view to first-class quality and cropping power in the progeny. I think if one took a very sweet variety and crossed it with an Apple of fine flavour one might get better results. I have a seedling Apple that is a perfect ball of sugar, and I should say that an Apple of this type crossed with a brisker sort would be more likely to produce a good Apple for general purposes than crosses of the type generally attempted. Let it be admitted that he who grows for market must have a good cropping variety, but it surely is possible to raise an Apple for this general purpose that is not like vinegar to eat and cannot, in fact, be used without an equal weight of added sugar. Fruit sugar is, beyond question, more health-giving than manufactured sugar, and sweet Apples more truly economical than sour ones. At any rate, our modern fruit raisers have mostly disappointed us. I can recommend King's Acre Pippin, a modern Apple, as of fine flavour and a good successor in February and March to Cox's Orange Pippin. Like Cox's Orange, King's Acre has Ribston blood in it. I believe the other parent of Cox's was Margil. D'Arcy Spice is delightful, but it grows very slowly indeed, so I fear it would have to be ruled out for

market, but why not use it for crossing with a view to getting a good all-round new Apple? I do not believe in the term "A good market Apple" being synonymous with rubbish as it practically is at present; the United States growers have managed to produce good market Apples that are not rubbish in quality, surely we can do so, too! W. J. FARMER.

FRUIT-TREE PLANTING.

THIS must, when the weather will allow, be pushed on, so that when there is yet much to be done it can be completed before the end of the year. Matters can often be expedited, when climatic conditions such as are now being experienced will not allow of planting being followed up continuously, if the stakes, for instance, required for the support of standard, bush, and pyramid trees are cut, their butt-ends sharpened, and driven in some 2 feet or sufficiently deep into the subsoil that they cannot afterwards move out of position, in advance. Thus there remains nothing to be done after the trees are planted but to secure them provisionally to the stakes, deferring the final tying until February, when the soil will have settled into place. Wall-trees should also be fastened to the walls in the same temporary fashion. With regard to the planting, this on some soils can be resumed soon after heavy rain, and in other instances a few days have to elapse before doing so. In the latter case a reserve of some old potting compost or soil which has been used for various purposes in frames and so on will play an important part, as it can be employed for surrounding the roots when difficulty is experienced in obtaining a crumb or breaking the staple to pieces. Care should also be taken to trim the ends of the broken roots with a sharp knife, and if they are found, when received from the nurseryman, to have dried during transit, to immerse them in water for about a quarter of an hour. As tree-planting is not complete unless the surface is mulched some 2 feet or more round the stems with litter or old hotbed material to keep out frost, the required quantity should be placed in readiness near where each tree is to be planted. K. P.

CORDON PEARS.

THE dozen varieties of Pears recommended on page 580 for cordon planting can hardly be improved, except in the case of the latest. I should be inclined to substitute Nouvelle Fulvie and Josephine de Malines for Bergamotte d'Esperen and Easter Beurré, which are not reliable; that is, they do not ripen at all satisfactorily. I often think one has to buy his experience with cordon Pears, despite the excellent advice given and possibly, to a great extent, followed. The fact remains that no system, however perfect, can meet the requirements of the many different varieties. The grower who has to deal with a light, sandy soil and no possibility of acquiring better material is faced with the alternative of scouring the neighbourhood in the hope of finding something a trifle heavier, adding some pulverised burnt clay and the like. Given this, circumstances will demand rather deeper planting and much careful attention afterwards in the way of mulching and watering. Failing the ability to do this, it will be found that some varieties are nothing like so satisfactory as where the ground is naturally well adapted for fruit-growing. In the case of the best varieties, for instance, I could never do much with Doyenne du Comice and Beurré Superfin on a light, sandy soil, but Thompson's and Beurré Hardy were very fair, and the late sorts named above, together with Glou Morceau, could also be relied on.

In early sorts I found Clapp's Favorite and Beurré Giffard about the best.

Given the adverse conditions of soil it is, perhaps, the great difference in the habit of growth of different varieties that is most perplexing to the amateur in cordon growing, rendering it difficult in many cases to regulate a right proportion of wood and fruit, for, whereas one sort will grow somewhat rampant, necessitating a nice discretion in the preparation of fruit-spurs, another will make hardly any growth and be a mass of fruit-spurs from base to summit. In the first case, it being neither advisable nor necessary to check growth on plants on the Quince by root-pruning, it is obvious the desired end must be effected by judicious work in the summer pinching, not doing this too early and all at once, and so provoking a lot of sappy after-growth, but leaving the operation until the wood is getting a trifle firm towards the base, and then, so far as each tree is concerned, at an interval of ten days or a fortnight.

Again, so far as those varieties that make a lot of fruit-spurs at the expense of wood are concerned, some of these spurs should be cut clean out at intervals, back-

the early and second early Apples give a far greater proportion of juicy fruits than the later kinds, Crofton Scarlet, Irish Peach, and Gravenstein being some prominent examples, and others one recalls to mind of somewhat similar season are Yellow Ingestre, American Mother, and the old Sussex Nanny Apple. Of course, we have cooking kinds notable for juiciness, but I was thinking of sorts that combined that characteristic with very fair quality and that are acceptable for dessert.—E. B. S., *Hardwick*.

Protecting Figs.—In severe winters Fig-trees in the open air, if left uncovered, often suffer much from cold; sometimes the whole of the young wood which should bear the next year's crop is destroyed from want of an hour or two's care in covering. Under ordinary circumstances the Fig-tree is a certain cropper, because it is not affected, or but slightly so, by the ungenial influences of spring, and if the young wood is protected before severe frosts sets in, the embryo Figs will be quite safe. It does not signify much what the protection consists of, provided it is sufficient in quantity. I have generally untied or unnailed all the branches, tied them together into

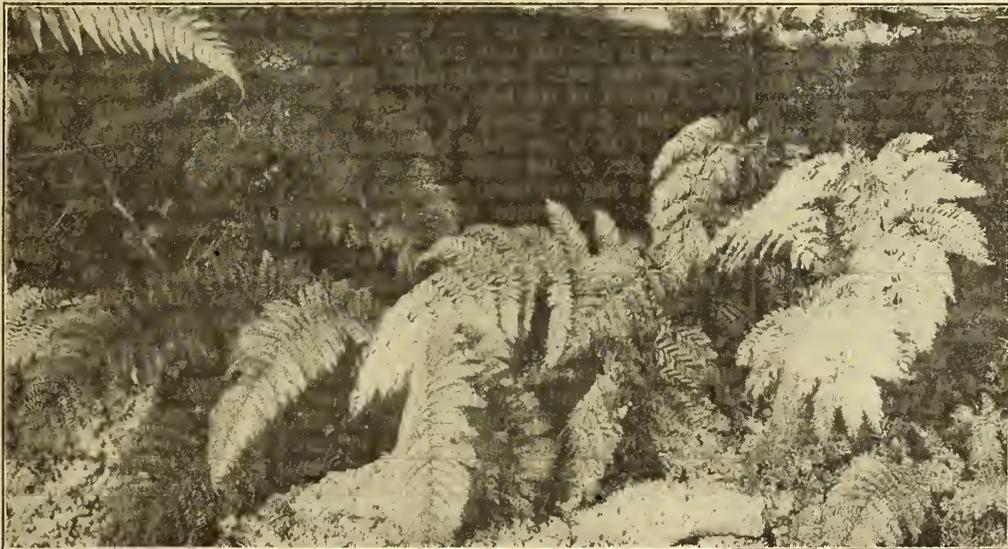

PLANTS AND FLOWERS.

FERNS.

FILMY FERNS IN CO. WICKLOW.

THE "Crape Fern" or "Prince of Wales' Feather Fern" of New Zealand (*Todea superba*) is one of the most striking, as also one of the most beautiful species of Ferns in cultivation. That it is not grown so extensively as it deserves is no doubt due to the fact that it is generally and erroneously held to be a plant of delicate constitution. This is not by any means the case, as but few Ferns are grown so easily as the Todeas. These plants do not require any artificial heat, this being clearly shown by the illustration we give to-day of *Todea pellucida* and *Todea superba* in the open air at Mount Usher, Co. Wicklow, where they have as companions many hardy perennial plants.

It is thus quite clear that the objection to growing these Ferns on account of the heat or special treatment they require is more imaginary than real. All that is necessary is a position naturally close, cool, and moist, and where the rays of the

Filmy Ferns (Todea pellucida and T. superba) at Mount Usher.

growth encouraged, and extra root-action promoted by feeding and watering. Three typical varieties that combine plenty of clean, healthy growth and excellent cropping qualities are Marie Louise d'Uccle, Beurré Hardy, and B. Alexandre Lucas. Mention above of cutting away spurs reminds one that where these begin to stand out too far from the main stem, as will happen with old trees, a portion may be cut away annually and new spurs formed with the best of the wood springing from the base. When the bearing wood is standing out too far from the wall it is difficult to protect satisfactorily in the spring from frost and in the autumn from birds.

E. B. S.

Hardwick.

NOTES AND REPLIES.

A cry for juicy Apples.—Juiciness in fruit is more pronounced from some soils, but is a special characteristic of some varieties of both Apples and Pears, and such fruit is very refreshing, although the quality may not always be first-class. In Pears, for instance, sorts like Napoleon and Passe Colmar are very juicy, but they have to take second place from a quality standpoint. Taken as a whole, I suppose,

two or three parcels, and wrapped some long straw round them, securing it with string, and afterwards fastening the bundles to the wall. This covering will save the young wood in the severest winters. For mild seasons and districts a few evergreen branches will suffice, but as when the wood is well ripened covering heavily and completely does no injury, it is as well to be prepared for whatever may happen and make all safe. The coverings may remain on till the end of March, and if the weather is unsettled at that time a part of the covering may remain a week longer.—E.

Unhealthy Peach-trees (J. H.).—The Peach shoots and leaves sent are devoured with black and green fly, and also mildewed. The fly should have been kept in check by the timely and frequent use of Tobacco water, or, better still, the points of the shoots should have been dipped in a strong solution of it, and for the mildew they should have been dusted over with flowers of sulphur, or have been syringed with sulphide of potassium and water, in the proportion of $\frac{1}{2}$ oz. of the former to a gallon of the latter. An east wall is not the best aspect for a Peach-tree, a full southern exposure being a much better one. The Roses on walls are also affected by exactly the same cause, and the remedy is the same as for the Peach-tree.

sun do not penetrate. In fine, the ideal position for Filmy Ferns is a spot where good light with absolute protection from every ray of sun can be secured. This theory is borne out by the fact that the strongest and the most numerous growths make their way towards the light.

NOTES AND REPLIES.

Lastrea Oreopteris.—Brought up from earliest childhood to love this native Fern and its delicious fragrance, it is a pleasure to find that in the Alps it seems to smell even sweeter still. Perhaps the purity of the air, free from even the faintest trace of smoke, may have something to do with the matter, but certainly in these glowing summer days the air on the mountain side is full of its sweetness where it grows abundantly. It is by no means an uncommon Fern in the North of England, but somehow it is rarely seen in the wild garden; hence this note, for the idea prevails that *Lastrea recurva* or *Foeniseii* is the Hay Fern and the only fragrant one that is worth growing. True, *Lastrea Oreopteris* is not evergreen like *L. recurva*, and it requires a trained eye to distinguish it from the common Male Fern at a little distance, so that, perhaps, is one cause

which makes it less of a favourite than it should be. Another cause may be that it is not the easiest of Ferns to transplant, unless in the young state and with a good lump of soil and roots. I have, indeed, heard some folk say they did not consider its foliage fragrant. To all such I would say, "Gather a young frond, bruise it slightly, and then apply your nose to it"; if then you do not recognise its aromatic sweetness, you and I will part company thereon!—E. H. WOODALL in *The Garden*.

TREES AND SHRUBS.

SOME DWARF JUNIPERS.

THE various dwarf Junipers are useful for planting in irregular-shaped masses on banks and in other places, whilst they may also be planted freely for cover. In many parts of the country the common Juniper does well on chalky soil, and the other dwarf kinds of exotic origin thrive on soil of a similar character. This lime-loving attribute makes the Junipers of special value for soils in which the various members of the *Erica* family refuse to grow. As a rule, they spread rapidly and soon cover a considerable area. If objection be taken to the bare ground between the plants when first planted it is easy enough to introduce some semi-wild plant until the Junipers cover the soil. Very little ground preparation is necessary for these shrubs. Remove coarse weeds and dig the ground over deeply enough to bury any Grass or other herbage. Coarse weeds will need to be kept down for a year or two, after which the Junipers ought to take care of themselves. On very dry soils they are sometimes attacked by scale, and when such is the case they should be sprayed over with a paraffin wash once every ten days during April and May. A fungus disease sometimes attacks Junipers, bright yellow, gelatinous masses of fungus growth encircling the stems. This is but one phase in the life-history of the fungus, the other stage occurring on leaves of Thorn, Mountain Ash, Bird Cherry, or some other member of Rosaceæ. The only way to stamp out this fungus is said to be by destroying every member of one host plant in the vicinity, but a good deal can be done to check its spread by removing and burning affected branches of Juniper.

The following kinds are available:—

J. COMMUNIS.—As a rule, this plant is met with as a spreading bush less than 4 feet in height, although under very satisfactory conditions it may form a shrub of the largest size, or even a small tree. It is widely distributed in Europe, N. Asia, and N. America, whilst it is wild in many parts of the British Isles, occurring above the limit of tree growth on the mountains of Scotland and also on the Surrey hills and other places. In some Continental countries, also in Ireland, there is a prostrate-growing form called *nana*. Amongst other varieties *fastigiata*, of stiff, fastigate habit, and *compressa*, a dense, stunted form, are worth growing.

J. PROCUMBENS is a dwarf bush from Japan which spreads widely and rarely exceeds a couple of feet in height. It is a good plant where a carpet-like covering is required, and can be used effectively towards the top of the rock garden. Cuttings and layered branches form means of increase.

J. SABINA, the common Savin, an attractive evergreen 2 feet to 12 feet or more in height and found wild in many parts of Europe, forms a good covering for banks and other bare places. The variety *humilis* is a dwarf form, of spreading habit, while *tamariscifolia* forms a number of rather erect branches from a fairly

close base. An American form of the common Savin sometimes called *J. S. prostrata* and sometimes included as a distinct species under the name of *J. horizontalis*, is a dwarf, spreading plant glaucous-green in summer and of a purplish hue during winter. It is sometimes alluded to as the Waukegan Juniper.

J. SQUAMATA, a native of the Himalaya and China, is another low-growing species rarely over 2 feet high, with spreading branches. It is, however, a rather scarce shrub and is less often seen than the previously mentioned kinds.

In addition to the above there are several dwarf varieties of *J. virginiana* which are useful for planting as isolated specimens in the rock garden, forms such as *compacta* and *dumosa* being specially worthy of notice. D.

HOME-GROWN TIMBER OF THE CLUSTER PINE (*PINUS PINASTER*).

By timber merchants generally the wood of the Cluster Pine is held in no great esteem, except as firewood or in the making of cheap and rough packing-cases. The tree, as is well known, is extensively planted in the reclaiming of sand dunes by the sea coast, and in France and Belgium has been turned to good account in that way. In this country the Cluster Pine attains to a large size when planted on sandy or gravelly soil, and on an estate in Kent some trees recently felled had produced timber at the rate of 1½ cubic feet per annum for a period of ninety years. Several of the trees, which contained from 80 cubic feet to 100 cubic feet of timber, were sawn into boarding and used experimentally on the estate, but with unsatisfactory results. Some of the boards were 3 feet wide, and, having been sawn to 3 inches in thickness, were considered to be well adapted for shed-cleaving and rough flooring. In one case thirty of the boards were used as flooring in a dry faggot shed, but in four years they were all so decayed that they fell to pieces when removed. When the size and age of the tree from which the planking was cut are taken into consideration, and remembering that the timber is so permeated with resin as to be heavier than that of almost any other Pine, it seems remarkable that the lasting properties are not greater. Out of doors, when used as fencing, no more satisfactory results were obtained. However, the recognised value of this Pine for reclaiming exposed sandy coasts and in the production of resin and firewood, as is the case in France, will alone make this tree valuable for economic planting.

A. D. W.

The Siberian Crab (*Pyrus baccata*).—A good deal can be said in favour of planting this tree in parks and gardens, for not only is it one of the most beautiful when in flower in May, but it is very attractive during autumn and winter also, when covered with its bright red fruits. It is found wild in N. Asia, and is perfectly hardy in the British Isles, where it grows into a specimen 30 feet or 35 feet high with a well developed, rounded head as far across. The flowers are white slightly tinged with pink, and the fruits are small, round, and Apple-like, and very firm. They ripen in October, and often hang on the trees until March. Many people prefer them to other forms of Crab Apples for making into jelly, and a good many are used for that purpose. There is a tree with very small fruits little more than ¼ inch in diameter that is sometimes given the varietal name of *microcarpa*. Some authorities, however, contend that the small-fruited tree is the type and the one with the larger fruit is only a variety.

There is still another tree that is sometimes mixed up with the Siberian Crab, that is *P. prunifolia*, which comes from much the same region, but is easily distinguished by its softer fruits, which ripen about the end of August, and by the calyx lobes being retained on the fruits until the fruits fall, whereas in *P. baccata* the calyx lobes are never retained until the fruits ripen.—D.

Timber of the Lebanon Cedar.—The wood of the Cedar of Lebanon grown in this country is much more valuable than is generally supposed. Several large trees that were uprooted during recent gales were, however, by no means readily disposed of, and in one instance the selling price was only a little above that of firewood. As showing the lasting properties of home-grown Cedar wood, a tree that was planted at Holwood, in Kent, by William Pitt just over a century ago was some years ago blown down during a storm and the timber converted into boarding 2 inches thick. Some of the planks were used in making a trough for sheep-washing, and, after having been subjected to drought and damp alternately for eighteen years, were found to be perfectly sound. The purpose for which the timber was used was one of the most trying to which wood can be applied, for, the trough being partially sunk in the soil and only containing water during the sheep-shearing, the changes from drought to damp were very considerable and well fitted to test the quality of the wood. Though somewhat brittle and short-grained the timber of the Lebanon Cedar is well adapted for indoor work, being of a reddish-white colour, light, easily worked, and taking on a nice polish. Several cabinets and room-panelling constructed of matured Cedar wood look little the worse after being in use for sixty years. Many trees in England contain at the present time upwards of 250 cubic feet of timber.—A. D. WEBSTER.

Robinia Kelseyi.—In 1903 this Robinia was originally introduced to the British Isles, and in the comparatively short time that has elapsed it has made many friends. It is a loose-habited, summer-leaving shrub with rather brittle branches. The flowers are rose coloured and very similar in shade (though smaller) to those of the Rose Acacia (*R. hispida*). They are produced very freely, several together, in short racemes from the buds of the previous year's shoots, the flowering time being June. After the flowers are over, curious pods, which are thickly covered with stiff, reddish bristles, appear. It grows well in ordinary garden soil, but should be sheltered from violent storms on account of the brittle nature of the branches. To induce the plants to increase in height it is wise to put stakes to the central shoots of young plants and keep the side shoots cut back a little until the desired height is obtained.—K.

Fendlera rupicola.—This is an attractive shrub when seen at its best, but it can only be expected to give good results when planted in a warm, sunny position, for it is a native of Texas and Arizona. It is related to the *Deutzias* and *Mock Oranges*, and in leafage is rather like the dwarf *Philadelphus microphyllus*. In a state of nature it grows about 6 feet high with a loose branch system. The flowers are white, each an inch or so across, and borne during May and June from axillary buds. The flowers differ from those of the *Mock Oranges* in the lower parts of the petals being narrowed until they are almost stalk-like in appearance. It should be planted in good loamy soil at the foot of a wall with a south or west aspect for preference.—D.

CHRYSANTHEMUMS.

GOOD OLD CHRYSANTHEMUMS.

The recent note in GARDENING ILLUSTRATED on that old variety, *Sœur Melanie*, and the appearance at the National Chrysanthemum Society's Exhibition of Mrs. G. Rundle and its sports, serves to show that some of the old varieties still hold their own. They must possess a better constitution than many of the newer kinds, which, brought forward with a flourish of trumpets and figuring prominently for a year or two, then disappear. It is not so much the fact that they are superseded by the newer kinds, as that they deteriorate to such an extent that the quality of the flowers after some half-dozen years or so is not nearly the equal of those produced in their younger days. Perhaps incessant feeding and what may be termed high pressure cultivation have a good deal to do with this, the plants being constitutionally weakened. Still, it is a pleasure to read that *Sœur Melanie*, which was sent out in 1868, is still grown and gives satisfactory results. The incurved variety Mrs. George

memory, namely, *Julie Lagravère*, sent out by Salter, of Hammersmith, in 1859. For many years it was grown as a border flower, where it held its own season after season, though the dark crimson-red flowers were occasionally cut by early frosts. One called popularly *Cottage Pink*, though I cannot find this name in catalogues, was much grown as a border flower for many years. A *Pompon*, President or Mr. Murray, with purple flowers, I have known for about forty years, and it is still to be seen in some of the gardens in this south-west suburb of London. In the case of exhibition flowers size counts for so much that many of the older kinds have dropped out, owing to their lack of inches. W. T.

NOTES AND REPLIES.

Chrysanthemums twenty-five Japanese of easy culture.—Would you kindly give me the names of twenty-five good Japanese of easy culture?—J. H. H.

[You do not say for what purpose you require the twenty-five varieties in question. We therefore assume the plants are intended for conservatory decoration or

(yellow, sport from *Money Maker*), *Yellow Triumphant* (yellow, sport from *La Triumphant*), *Miss Emma Roupe* (mauve-pink), *Phœbe* (pink), *Heston Bronze* (bronzy terra-cotta), and *Terra-cotta Soleil d'Octobre* (terra-cotta, sport from *Soleil d'Octobre*).]

Single Chrysanthemum Sylvia Slade.—Some consider this variety a little formal, but others admire it. I saw it well done in a villa garden the other day. The growth is good and the blooms, which are of moderate size, have a good deal of substance when well grown. The flowers are well described as being of a "rosy garnet colour" with a broad white ring at the base of the ray petals.—S. A.

Chrysanthemum Eden.—This is often too late for cold districts when in the open, but is valuable for flowering under glass in these places. Although generally grown without disbudding, it is excellent when this is performed. The colour is a clear rose, and judging from some plants I saw the other day, the variety flowers very freely.—S. A.

ROCK, ALPINE, BOG, FERN, AND WATER GARDENS.

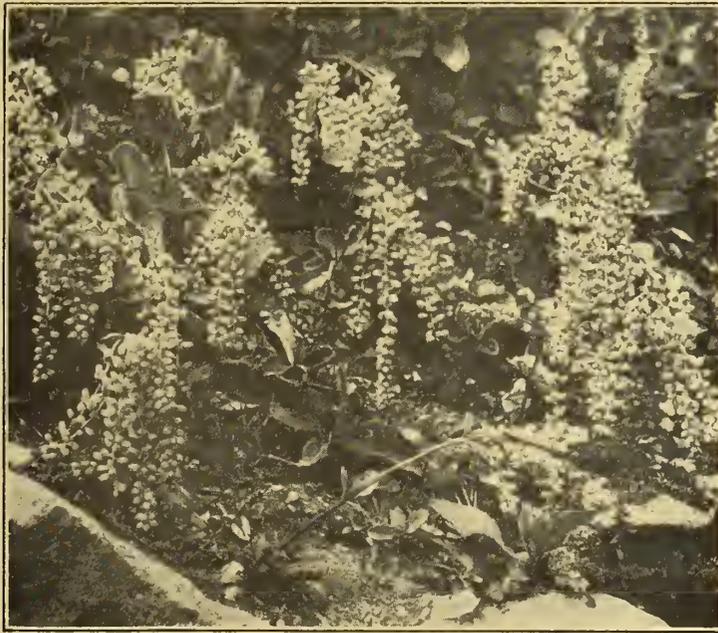

COTYLEDON SIMPLICIFOLIUS.

This distinct species has been freely exhibited during the last two seasons, and in June, 1915, when shown by Miss Willmott and Messrs. Waterer, Sons, and Crisp, gained an Award of Merit. The spatulate, slightly crenate leaves are fleshy, midway in this respect, as also size, between those of *Lewisia* *Cotyledon* and *Sedum* *spurius*. In no other respect can the comparison be pursued. Possessed of a stoloniferous root-stock, though minus the pernicious, weed-like character of the *Stoncrop* noted, perennial habit with a freedom of growth is ensured, and these, wedded to a plant of unusual distinctness, should go far towards providing for it a home in many a rock garden. It is likely to be best suited in the drier positions, in semi-vertical places, with loam and disintegrated rock in nearly equal parts as its chief food, or loam and the oft-recommended mortar-rubble so serviceable to many rock-loving subjects. A fairly sunny aspect in which the racemes of drooping yellow flowers may appear to advantage should be chosen. Comparatively poor or rocky soils appear to invest it with a sturdier habit, and, even if dwarfed thereby, it does not suffer in decorative effect. It is 6 inches high. The picture shows the flowering character, with some barren (unflowered) rosettes in the foreground. It is easily raised from seeds or increased by runners or division.

E. H. JENKINS.

NOTES AND REPLIES.

Sedum Sieboldi.—I have known and grown this for many years and seen it in greater or less perfection in a variety of gardens in many parts of the country, but never so fine as a few weeks since at Earham Hall. Possessed of a beauty all its own, and giving of its best in autumn, when beautiful-flowering alpinines are none too plentiful, it is one of those plants which, despite its merits, has not received adequate attention from the rock gardener. For this particular phase of gardening *Siebold's Stoncrop* is eminently suited. Beside it the variegated form is sickly, weak in colour, and weaker in constitution in that particular garden. Moreover, the fine contrast of glaucous leafage and crimson flower trusses, so effective in the typical kind, was wanting. Though it will grow and succeed in any light, loamy soil, I find that a stiffish loam freely mingled with old mortar and a sunny exposure are much the best for this handsome *Stoncrop*. —E. H. JENKINS.

Cotyledon simplicifolius at Friar Park.

Rundle, whose pure white blossoms, though small, are exceedingly symmetrical in shape, is one year older, for it was distributed in 1867. In time it produced a soft yellow sport, Mr. George Glenny, from which, after a while, a much deeper yellow, Mrs. Dixon, was obtained. It was quite reminiscent of olden times to see those varieties again shown, and I venture to think that they were as much admired as any.

It is, perhaps, among the Japanese sorts that the greatest changes take place, for out of the 130 or so varieties of the different sections of this race, which are mentioned as the best in the centenary edition of the National Chrysanthemum Society's catalogue, it is questionable if there is one other than *Source d'Or* that is in general cultivation. This was sent out by M. Délaux in 1882, and is still largely grown, especially for cutting. This must have a good constitution to enable it to hold its own all these years, while perhaps the most popular *Pompon* of to-day is *Mdlle. Elise Dordan*, despite its thirty years' service. A considerably older kind of *Chrysanthemum*, however, appeals to one's

for cut flowers. The sorts we have selected are those that yield a good display of blooms of medium size and make excellent decorative plants. If you desire us to give you the names of exhibition varieties kindly let us know? We recommend the following Japanese varieties for the purpose suggested:—*Money Maker* (white), *Rayonnante* (shrimp-pink), *Soleil d'Octobre* (yellow), *Bronze Soleil d'Octobre* (bronzy, sport from last-named), *Caprice du Printemps* (deep rosy-pink), *Kathleen Thompson* (crimson, sport from last-named), *Butler's Caprice* (red, sport from *Caprice du Printemps*), *Cranfordia* (yellow), *Source d'Or* (terra-cotta), *Crimson Source d'Or* (crimson, sport from last-named), *Freda Bedford* (bronzy-orange, shaded apricot), *Vivian Morel* (mauve-pink), *Chas. Davis* (rosy-bronze, sport from last-named), *Lady Hanham* (rosy-cerise, sport from *Vivian Morel*), *Lizzie Adcock* (rich yellow, sport from *Source d'Or*), *Market Red* (velvety metallic red), *Mrs. Andrew Walker* (deep coppery-red, sport from *Freda Bedford*), *La Triumphant* (rose, shaded white), *La Negresse* (bright crimson, tipped gold), *Yellow Money-maker*

GARDEN PESTS AND FRIENDS.

SOME GARDEN PESTS.

PREVENTION is better than cure is an axiom that might well be applied in dealing with the majority of garden pests, for it is far better to anticipate the attack and take measures to render it practically harmless than to wait until the foliage is half ruined or fruit half eaten before getting to work. The above reflections were due to reading the oft-repeated query to the Editor as to the condition of Violet foliage. In the case of Violets planted in the open, on which it is difficult to use the syringe effectually, I always found the best prevention was to mulch early in the season with fresh horse droppings, the aroma from which is decidedly objectionable to red spider, the great enemy of Violet foliage. All stone fruits and cordon Gooseberries should get a thorough wetting as soon after the fruit is set as possible with some form of insecticide that will render the foliage distasteful to the insect. These remarks apply to all those flowering plants liable to attack from the particular fly that is the origin of the leaf-boring maggot. It is clearly established that the trouble with the foliage of tuberous Begonias is due to thrips, which can generally be warded off or, at any rate, minimised by a slight mulching of cocco-fibre always kept moist. The dew arising from this settles on the under-surface of the leaf and there is very little trouble with the insect. The above are a few of the many cases where, as above noted, prevention is better than cure.

In the case of larger insects like the wasp and earwig one can, in a measure, deal with the former by the destruction of queens and the early taking of nests, but with earwigs it is different, their habits not being very clearly known. One thing, or rather two things, are clear, that they are partial to certain districts and are most troublesome in hot, dry summers. This being so, the attack on all stone fruits, especially Peaches, Nectarines, and Apricots should be anticipated by getting traps in position quite early in the season, starting, of course, with the earliest ripening fruit. The earwig is very quick to detect the slightest sign of ripening, and it is difficult to understand how it can manage to perforate the skin while yet the fruit will hardly yield ever so slightly to the pressure of the thumb. The grub known as the Leather-jacket seems likely to be troublesome, and it may be well to dip all the Cabbage family before planting (right up to the collar of the plant) in a thick puddle of lime and soot.

Hardwick.

E. B. S.

Combating the Celery-fly.—Many gardeners have been troubled with the Celery-fly this season, and various are the remedies which have been tried to eradicate the pest. Soot has been suggested as a cure. I have not, however, found soot answer always, and lime is about as effective, the reason being, I presume, that it is not easy to distribute either soot or lime on the undersides of the leaves. I would rather depend upon a solution of Quassia chips and soft soap, syringing the plants once or twice a week almost from the time they are planted in the trenches. This I regard as most effective.—F. W. D.

—This has been very troublesome again this autumn. In some gardens the attack has left the plants almost leafless. In my own garden I find that the plants which have been fed are suffering the worst. Plants in a somewhat starved condition have been slightly attacked. About the end of October, when looking over a large private garden, I noticed the Celery had scarcely a bad leaf. The grower told me he had given the plants several dustings of soot, applying it to the leafage early in the morning when damp.—DORSET.

GARDEN FOOD.

THE CHESTNUT SEASON.

I HAVE acres of bearing trees, but only the boys and birds and rodents benefit by them. In France and Italy poor people, during the fall and winter, often make two meals from Chestnuts. At this season it is well to make good use of the Chestnut. W.

CHESTNUT SOUP.—Slit and boil in water till nearly tender $1\frac{1}{2}$ lb. of Chestnuts. Remove the outer rind, and then peel them and drop them into cold water. Next cook the Chestnuts in a quart of rain-water, together with a peeled Onion, a stalk of Celery, and half a Bay-leaf. When the materials are tender rub all through a fine sieve, return the purée to the stew-pan, and reheat with half pint of milk, previously boiled. Reduce a little, season lightly, and lastly add a little Lemon-juice.

CHESTNUT CROQUETTES.—Slit and boil in water for half an hour 1 lb. of Chestnuts; then drain, and cook them in the oven for another half-hour. Remove both the shell and skin, and rub the Nuts through a sieve or chop them finely. Heat up in a stewpan one gill of milk or cream, add the Chestnut purée, also 1 oz. of butter. Season very lightly. Heat up thoroughly, and add the finely-grated rind of half a Lemon; then stir in the yolks of three eggs, and spread on to a dish to get cool. Make up the mixture into ball shapes of even size, egg and crumb them carefully, then fry in deep fat to a golden colour. Drain, dish up, and garnish with quarters of Lemon and Parsley.

CHESTNUT AND LENTIL CUTLETS.—Chestnuts and Lentils make an excellent combination. Mix one pint of Lentil purée with half pint of Chestnut purée cooked as above directed. Stir in a small Onion, previously minced finely, and fried to a golden colour in 1 oz. of butter. Now add a few chopped, peeled Mushrooms, and a teaspoonful of finely-chopped Parsley; season to taste and stir in two egg yolks. When the mixture is cold, shape into even-sized cutlets, egg and crumb them carefully, insert a small piece of macaroni in each cutlet, and fry to a golden colour in hot fat. Drain, dish up, and garnish with crisp Parsley.

CHESTNUT STUFFING.—Scald about a score of fine, fresh Chestnuts in very hot water for ten minutes, skin them, and put them in a little good gravy; allow them to stew gently for about half-an-hour, then add a glass of white wine, a little Pepper, salt, and a blade of Mace. When quite soft, pound lightly, and stir in 1 oz. of butter.

MARRONS GLACES.—These delicious sweets are very expensive to buy, but very easy to make. Remove both skins from some Italian Chestnuts, put them into hot water, and let them simmer until they are tender, but not soft. Simmer half a pint of water with $\frac{1}{2}$ lb. of sugar until the syrup looks clear, then put in the Chestnuts carefully, and simmer until they look quite clear. Take them out, and let them cook on a sieve, and in the meantime boil up the syrup until quite thick, then add a few drops of Lemon juice and about half a teaspoonful of vanilla. Stir well, and when the syrup whitens put in the Chestnuts one at a time. See that they are well covered with the syrup, then remove carefully and put into paper cases.

NOTES AND REPLIES.

Turnip-rooted Cabbage (Swedish Turnip).—The Turnip-rooted Cabbages differ from the Kohl Rabi in that instead of having the stem swollen above ground, they produce, partially buried in the soil, a thick root nearly as long as broad resembling a huge Turnip, of which the flesh is yellow in the Rutabagas, or Swedish Turnip, and white in the other kinds. All the varieties like a stiff soil and always do best where the climate is moist. They are not at all affected by frost, one of their chief recommendations being their extreme hardiness. They are best sown early in May, thinning out to 10 inches apart. The roots are eaten boiled, and are in the best

condition for table if lifted before they have reached their full growth. The Turnip-rooted Cabbage is an excellent vegetable, and deserves far more attention than it at present has. In many places the roots are lifted and clamped like Potatoes.

The best Blackberry for northern gardens.—The best Blackberry for northern gardens is the Parsley-leaved one, *Rubus laciniatus*. I have tried several of the American Brambles, such as Wilson Junior, and others, but none of them came up in point of real value to the older Parsley-leaved one. It is often difficult to get the American varieties to ripen well in the north, whereas the one mentioned never fails to ripen its fruits before the late autumn. Even selected plants of the common wild Bramble of our hedges are useful for covering rough fences where the fruit is appreciated for pies, in combination with Apples and Plums, or jelly, and even for jam. The Blackberry has, however, the defect as a jam fruit of being often hard, and is better when made into jelly. In too many cases in gardens the Brambles do not receive the attention they deserve. They may be trained in the same way as Raspberries, but to taller, upright stakes or to wires strained between posts, and I have seen them doing well on arches well exposed to the sun. Brambles should have good, well-manured soil, with occasional doses of liquid manure, mulching in dry weather.—S. A. M. D.

Potato Great Scot.—Though a second-early or midseason variety, this Potato this year has given splendid results and the crop has matured earlier than usual. As regards the eating qualities it is of excellent table quality, and, what makes it more valuable, it is a splendid keeper, with round tubers, shallow eyes, and admirably adapted for strong soils, as it is a robust grower, having a strong haulm. With me it is quite free from disease. It is a very heavy cropper, with no waste, as the crop is notable for its absence of small or useless tubers. A few years ago this variety was one of the few which received an Award of Merit from the Royal Horticultural Society for the quantity of its crop and its good quality, as it was cooked to test the latter—an important point that should not be overlooked in any trial of Potatoes.—*The Garden*.

The Pecan crop short.—Reports show that the Pecan crop in Texas is short this year compared with other years. This fact and there being an increased demand for Pecans have caused the price to range somewhat higher than usual. In some places the better grades have sold as high as 18 cents per pound.

[In London they are not, so far, to be had.—Ed.]

Pear Comte de Lamy.—This delicious fruit is not yet, after nearly a hundred years' existence, so widely known as it should be. Raised by M. Simon Bouvier, of Jodoigne, Belgium, about 1828, it was dedicated to Professor Curtet, of Brussels, its correct name being Berré Curtet. It has suffered badly, like so many good Pears, at the hands of the rechristeners. However, Comte de Lamy it is in England, and so it will have to remain. Rather on the small side, of pyriform or sometimes Bergamotte shape, its appearance says nothing for it; but perhaps that is all in its favour. How much more interesting it is to bring forward the Cinderellas of the fruit-room rather than the corpulent sisters who attract every eye! Certainly in "every well-regulated garden" a space should be found for this delicious October fruit. Mr. Blackmore at Teddington turned upon it the downward thumb, but his soil was not kind to Pears. In any medium soil it does well, and in a light sand excellently.—E. A. B., in *Garden*.

ROOM AND WINDOW.

WILSON'S BARBERRY.

This graceful and bright-berried plant is charming for the bold rock garden, and very useful also in a cut state for the house; best, perhaps, in a Japanese vase, the shoots fixed in glass holders. When cut it will remain in a good state for weeks.

NOTES AND REPLIES.

Spanish Irises for cutting.—Few plants give more delightful blossoms for cutting for table decoration than Spanish Irises. All who would have them another year should plant the corms in November, as I

INDOOR PLANTS.

WELL-TRIED PLANTS.

"E. B. S." has an interesting note on page 566 on some old and well-tried plants that still hold their own, despite the number of new varieties that have been distributed since they were first sent out. The variety of Ivy-leaved Pelargonium which he mentions, namely, Galilee, was raised by M. Lemoine, of Nancy, and distributed in the spring of Jubilee year, 1887. Old as it is, there are two varieties still much grown which are older, namely, Souvenir de Charles Turner and Mme. Crousse. This latter is the oldest of all, having been sent out in 1881 or 1882. A visit to

particularly Henry Jacoby (crimson), West Brighton Gem (scarlet), and Vesuvius (scarlet). These have been generally grown for many years. In the case of Fuchsias the popularity of old and well-tried varieties is particularly marked, especially among those that are grown into large specimens and employed for the flower garden during the summer. A probable reason for the favour shown to the older kinds is that many of the newer forms have very large and heavy blossoms, which do not resist the wind so well as the smaller blooms of the older ones. Of varieties with white corollas undoubtedly the favourite for growing out of doors is Mme. Cornellison, which was sent out in 1860 or 1861. Its stiff growth enables it

Wilson's Barberry in fruit in a Japanese vase.

have found from long experience that, put in then, the results are invariably finer. They make a fine show if planted in groups of eighteen or so in mixed borders, and any fairly light soil suits them. I give mine a mulch of old manure in the late autumn, and no winter, however severe, seems to affect them. They may be left two or three seasons, but after that it is advisable to lift and replant. Care should be taken not to plant the corms too deeply, 3 inches being sufficient.—WOODBASTWICK.

"The English Flower Garden and Home Grounds."—New Edition, 12th, revised, with descriptions of all the best plants, trees, and shrubs, their culture and arrangement, illustrated on wood. Cloth, medium 8vo, 15s.; post free, 15s. 6d. Of all Booksellers or from the office of GARDENING ILLUSTRATED, 63, Lincoln's Inn Fields, London, W.C.

Covent Garden Market in the spring, or a walk through the fashionable London squares during the summer, will show the great extent to which these varieties are grown, while if note is taken of the contents of the costermongers' barrows in the poorer neighbourhoods much the same result will be obtained. It is very interesting to note the different subjects offered by the costermongers, many of whom obtain their supplies from the market after the wants of the better-class customers have been supplied. Sometimes a specimen or two of quite an uncommon plant may be obtained in this way. In the case of Zonal Pelargoniums "E. B. S." refers to the varieties Paul Crampel and King of Denmark. There are, however, still older varieties which are largely grown, par-

to withstand rough weather well, while it is harder than most of the others. Rose of Castile is even older than this, while, though I do not know the age of Mrs. Marshall, it was certainly a popular market kind nearly fifty years ago. Other old kinds that show no decline in popular favour are Scarcity, Wave of Life, Phenomenal, Amy Tye, Lady Heytesbury, Lord Beaconsfield, and Ballet Girl. The flowers of this last are, like those of Phenomenal, large and double, and the habit of the plant is so sturdy that they resist winds well. Of Chrysanthemums a few old and well-tried kinds still hold their own, while of Heliotropes, besides the variety Piccoli mentioned by "E. B. S.," such well-known kinds as Lord Roberts and Miss Nightingale, both richly coloured and

fragrant varieties, are still extensively grown. The double-flowered *Lobelia speciosa*, known now as Kathleen Mallard, which is the same as an old variety grown many years ago and long lost to cultivation, has made many friends during its second appearance. It is, however, of little use for bedding, as the blooms are spoilt by wet weather. Many other plants that still retain their old-time popularity might be mentioned, but enough has been given to show that a certain percentage of them still remains in the foremost rank.

W. T.

NOTES AND REPLIES.

Azalea Roi des Belges.—I have an *Azalea* called *Roi des Belges*. (a) Please tell me the botanical name? (b) Two blooms made their appearance a fortnight or more ago, but now the plant seems to hang fire (it is in a large pot). Does it require heat? (c) How is it propagated?—BEGINNER, *Eastbourne*.

[This is a variety of *Azalea indica*. If you wish the plant to flower now, then you may put it into heat, but if not, then the better way is to allow it to bloom naturally in the greenhouse. An excess of water or too little must be guarded against now that the plant is coming into bloom. *Azaleas* are increased from cuttings as also by grafting, but, as we said in regard to *Erica hyemalis*, unless you have the proper conveniences you cannot hope to succeed.]

Erica hyemalis.—(a) When should *Erica hyemalis* bloom? (b) What treatment does it like? (c) How propagated?—BEGINNER, *Eastbourne*.

[This blooms in the winter and early spring months. It should be given greenhouse treatment. This *Erica* is increased from cuttings, but unless you have the proper conveniences for doing so we can hold out but little hope of your succeeding. Directly after your plants have ceased flowering you ought to cut them into shape, shortening back the long, vigorous shoots to one-third their length, then place them in the greenhouse or in a frame, where they will soon start into growth. As soon as the young shoots are about half an inch long repot in sandy peat, which must be pressed down very firmly. After this the plants should be kept in the greenhouse till they have recovered from the check, when a cold frame is a good place for them till towards autumn, when the nights grow cold, at which time they should be removed to the greenhouse.]

Begonia Gloire de Lorraine.—I bought two plants of *Begonia Gloire de Lorraine* in July last. They were then in bloom, and still are, but show signs of failing. Please say: (a) What I can do with them and (b) how are they propagated? I repotted into larger pots about a month ago.—BEGINNER, *Eastbourne*.

[There was no need to repot your plants, which, late in the spring when they have finished flowering, should be cut back to where the first blooms have been produced. In a short time young shoots will be pushed out towards the base of the plant, these, when they are from 1½ inches to 2 inches long, forming the best cuttings. They should be cut off with a sharp knife close to the main stem, and be dibbled into well-drained pots of sandy soil, given a gentle watering, and placed in a close propagating case in the stove. Water only when necessary, and open the case occasionally to dry up any of the superabundant moisture. In about three weeks the cuttings will have rooted, when they may be hardened off and potted singly into small pots. Pot them on as necessary, and when the pots in which you intend to flower them are full of roots an occasional dose of liquid-manure is very beneficial. A suitable compost in which to grow this *Begonia* and its several forms is a mixture of loam and

leaf-mould, with, if the loam is inclined to be heavy, plenty of silver sand. You may retain the old plants, potting them when they have started freely into growth after they have been cut down, but the best plan is to raise young plants every year from cuttings.]

Primula malacoides.—It is pleasant to find how this *Primula* is finding its way into the greenhouse of the amateur. It is so easily raised from seeds and gives such a quantity of its purple flowers that it is most valuable to the amateur who wishes to brighten up his little greenhouse in winter and early spring. I saw a nice lot the other day in a small greenhouse containing a miscellaneous assortment of plants, and this *Primula* seemed to do well under such conditions.—S. A.

The Heliotrope as a climber.—Too often we think of the *Heliotrope* only as best fitted for the greenhouse stage or the flower garden, forgetting its value as a climber, in which way it is easily grown, either in large pots or tubs or planted out where light can reach both root and plant. To grow *Heliotropes* quickly over rafters one must be prepared to sacrifice blossoms for a season, pinching the shoots to induce lateral growths, and potting the plants in a compost of old loam and leaf-soil with mellow dung added. Mulchings of manure now and again will do much to stimulate them, and the second season should see a plentiful supply of blossoms.—WOODBASTWICK.

ORCHIDS.

SOME EASILY-GROWN ORCHIDS.

(REPLY TO "F. G. H.")

An impression is prevalent that to grow Orchids satisfactorily special facilities, as well as a particular knowledge of their requirements, are essential, and still further that they are expensive. Many of the best Orchids can be grown as easily as *Fuchsias*, or other greenhouse plants and Ferns, and they can be procured just as cheaply. The only knowledge required is as to the best varieties to commence with. One of the oldest Orchids in cultivation, and one of the most suitable for winter flowering, is *Cypripedium insigne*. This can be grown in a cool greenhouse in which the winter temperature is maintained at about 50 degs. at night. It will bloom from November onwards, and the flowers last for several weeks in perfection. Some later introductions have produced considerable variations. The potting should be done in early spring, shortly after the flowers have been removed, and the compost should consist of good fibrous loam and peat, intermixed with rough sand and a little *Sphagnum*. The plants require a liberal amount of moisture at all seasons of the year, but with low temperatures they should be kept rather drier at the roots, and the moisture in the atmosphere be reduced. In summer the plants may be accommodated in a cold frame, shaded from the direct rays of the sun during the hottest part of the day.

In addition to the above there are many hybrids which have been derived from the intercrossing of *C. insigne* with other species. These may be procured cheaply, and as they possess vigorous constitutions they are worthy of every consideration. *Sophronis grandiflora* will do well suspended from the roof in a cool-house. This is one of the most attractive of the cool-house species, its brilliant orange-scarlet flowers, produced in the depth of winter, being always welcome. There are several cool *Oncidiums* which are useful for winter flowering, two of the most useful being *Oncidium incurvum* and *O. ornithorrhynchum*. *Masdevallia tovarensis* is a charming white-flowered variety that produces its blooms in the depth of winter. This species should be protected from the scorching rays of the sun at all seasons of the year. *Lycastes*, of which *L. Skinneri*

is the most attractive, can be cultivated in a house in which 55 degs. would be the average temperature. The flowers last a long time in perfection. Under similar conditions many of the miniature-growing *Cattleyas* and *Laelias* of the Mexican sections may be included. The *Laelia pumila* section is especially suitable for basket culture and flowers during the late autumn months of the year. *Laelia harpophylla*, which produces its orange-red flowers in the early spring, may also be grown here, and the more showy *Oncidium Forbesi* section may also be included. All of the above are procurable at a trifling outlay, either in an imported or established condition.

AN ORCHID FOR AMATEURS.

ONCIDIUM AMPLIATUM MAJUS.

This is one of the showiest and best of the *Oncidiums*, and although an old species, it still holds a foremost place. This produces its bright yellow flowers during the months of May and June, and these, if not sprinkled with water from the syringe, will remain in perfection for a considerable time. *Oncidium ampliatum majus* is of easy culture, and succeeds well when grown in pots. It produces large, roundish, and much-compressed pseudo-bulbs, each 3 inches or 4 inches in diameter, streaked with purple and red, turning when old to a dark brown. The leaves are broad, of thick, leathery texture, upwards of a foot in length, and bright deep green in colour. The scape, which is erect and attains a height of about 3 feet, is much branched and produces flowers in abundance. These are quite white at the back and bright yellow in front. The sepals, almost entirely hidden by the other segments, are pale yellow with a few brown blotches, the petals bright canary-yellow, and the lip even brighter.

Oncidiums are naturally epiphytal, growing upon branches of trees; therefore it is very necessary that they have good drainage. They require to be potted firmly in a mixture of good fibrous peat and *Sphagnum Moss*, with a few nodules of charcoal. The plants, which should be raised on a cone-shaped mound above the rims of the pots, enjoy, when growing, a copious supply of water, but during the period of rest only enough should be given to keep the bulbs in a plump and healthy condition. They can be grown in the hottest part of the *Cattleya*-house or in any position where plenty of heat can be maintained, always taking care that the atmosphere is moist.

Dendrobium regium.—This may be best described as a summer-flowering *Dendrobium nobile*. It is a very desirable plant and deserves a place in any amateur's collection, as it blooms from July onwards, a period of the year when *Dendrobium* flowers, especially those belonging to the noble group, are not to be had. The colour of the flowers is a light rosy-purple, the throat of the lip clear yellow surrounded by a zone of creamy-white. The maroon disc, characteristic of *D. nobile*, is absent in *D. regium*. Repotting must be done later in the season than in the case of *D. nobile*, and, as a rule, it should take place a few weeks after flowering. *Osmunda fibre* and *Sphagnum Moss* in equal parts make a good rooting medium. The receptacles, either pots or pans, must be filled to one-third of their depth with drainage. During growth a warm, moist atmosphere is needed, and the plants, when they are well rooted, should be afforded plenty of water. When the season's growth is complete a cool and drier position is needed, but sufficient water ought to be given to maintain the pseudo-bulbs in a plump condition.—B.

OUTDOOR PLANTS.

PETASITES JAPONICA.

The species of this genus are not favoured by gardeners because of the rapid spread of their roots and the difficulty of eradication once they get established. In cool, moist loams, or even clay, some of the kinds are among the worst weeds with which the gardener has to deal. Under no circumstances should the more troublesome kinds be introduced into the border or other place where, for the reason named, they are likely to become a nuisance. That most esteemed by gardeners is

P. (TUSSILAGO) FRAGRANS (Winter Heliotrope), because of the time of its flowering and the fragrance—one cannot add ornamental character—of its flowers. That it was so esteemed and sought after at one time may be gathered from the fact that in my old Tooting days it was specially cultivated in pots, and in flower

the variety would associate well with some of our fine-leaved subjects. I have no experience of it at such a size, and would be interested to hear from anyone who has.

E. H. JENKINS.

THE ADONIS.

At one time there was but little choice among these, but we now have several fine new species.

ADONIS VERNALIS.—This, though first grown close on 300 years ago, still remains a general favourite, the handsome flowers, bright yellow, opening in March or April. It thrives best in a rather heavy, moist soil. It does not like disturbance, and it is not advisable to divide it, if possible to avoid it. Young plants can be raised from seeds, which ought to be sown as soon as they are ripe. Old seeds are slow to germinate, and may lie dormant for a year.

A. PYRENAICA often blooms as early as May, although July is said to be its normal flowering season. It is rather taller than *A. vernalis*, but has smaller flowers, its

sults, though in this position it is a little later than in a heavier and moister soil with more sun. *Adonis amurensis* is one of the most valuable of our early flowers, and well deserves some protection from the weather while in bloom.

TIME OF PLANTING.—Autumn is the best time for planting these varieties of *Adonis*, though they may be put in as late as November should the weather keep open. Some dealers supply the plants in pots, and they can be planted from these with but little disturbance of the roots.

S. ARNOTT.

NOTES AND REPLIES.

Erica cinerea.—I have two good-sized plants of Scotch Heather in bloom (white and pink). (a) Is the right name *Erica cinerea*? (b) What is the treatment when it goes out of bloom? (c) How is it propagated?—BEGINNER, *Eastbourne*.

[Yes, the Scotch or grey Heather is *Erica cinerea*. It is improved by cutting over in the early spring before growth starts, and is easily increased by division.]

Hardy plant notes.—The following notes by the late J. Wood, of Kirkstall, in *The Garden* of December 5th, 1891, are very interesting:—

OXALIS LOBATA.—This is one of the more seldom seen species, and I believe with many the idea prevails that it is not hardy. This is the point on which I wish especially to speak, but only two or three words of fact. Surely I need not do more than report that it stood out here unprotected all the last severe winter. If that is not enough, I know a friend whose climate is even worse than this—colder, a lower elevation, and heavier land. In his garden this little gem withstood the rigorous of 1890-91 winter.

OURISIA COCCINEA.—There has been the usual lamenting, owing to the non-appearance of flowers this autumn. As I believe I said last year, though the plant grows well in shade, it is all the better for sunshine if the moist condition of the soil can be maintained. I have recently proved plants to flower better in that way. One thing is certain, if you grow the plant well and manage to keep the leaves on in winter, you afford it the best possible chance to flower, and if you can get ever so few of its neat dwarf spikes of drooping scarlet plumes you will not begrudge the little pains needed.

About 1886 I spent a day in Mr. Wood's garden at Kirkstall, full of all sorts of treasures, many of which came from Mr. Wolley Dod's garden. In 1893 Mr. Wood spent several days here. He was very much taken by the brown slate chips, especially in the Lledr valley. I remember sending him a truckload to Leeds.—E. CHARLES BUNTON, *Coed-Derw, Bettws-y-Coed*.

Iris bakeriana.—I first grew this *Iris* twenty-five years ago, and I shall ever retain the pleasure it afforded me when it flowered. Unhappily, it succumbed, as it has since done, and its loss was, I think, due either to late frosts injuring the foliage before it was fully matured, or the wet winters we so often experience. A bulb which requires to be lifted annually has, in my opinion, many obvious drawbacks, and possibly the want of a complete rest may have had something to do with the loss of *I. bakeriana* at various times. On the whole, however, I am inclined to attribute it to late frosts, which have frequently been fatal to other exquisite *Iris*es, e.g., *I. Rosenbachiana*, *I. orchoides*, and other bulbs whose leaves were scorched by frost ere they had completed their growth.

Petasites japonica, var. gigantea (syn. Nardosmia japonica).

often sold at the seemingly ridiculous price of thirty shillings per dozen. In all probability the name Winter Heliotrope assisted to this end, since I do not recall a single instance of a "repeat order." This, notwithstanding, there is room for the species in the woodland where it may be permitted to run its course. The late Latimer Clark was very fond of it, and every year a few well-flowered plants in pots always found their way into his cool conservatory.

P. JAPONICA has flowers of a creamy hue—not fragrant, so far as I remember—and produced in a more club-shaped inflorescence than the one already named. At flowering-time it may be a foot high or less, and is usually seen minus leaves at that time. The flower-heads are not attractive, though the foliage is handsome in outline. An even greater development of this Japanese kind is the variety *gigantea*, also called *Nardosmia japonica*. This is said to attain to 6 feet high, the leaf-stalks being used as Rhubarb is in this country. Given such development,

main recommendation being its later blooming. It likes a lighter soil than *A. vernalis*.

A. VOLGENSIS.—This comes in midway between *A. vernalis* and *A. pyrenaica*. It has flatter and thinner stems than *A. vernalis*, but the flowers more resemble those of that species than those of *A. pyrenaica*.

A. AMURENSIS.—This is one of the greatest gains of recent years. This is partly due to its earliness and partly to the beauty and variability of the flowers. In warm, sheltered places and in good years it sometimes blooms as early as January, and in February is usually in full flower. It is about 9 inches high, and is highly attractive even before it blooms, so Fern-like is the foliage. The bright yellow flowers are each about 2 inches across, but there are several forms—one with double blooms and another with flowers with a greenish centre. This species likes a sunny place in a moist, rather heavy loam, but I have grown it for years in a half-shaded situation in light loam with satisfactory re-

With and without peat, with plenty of sand and with and without leaf-soil, amply drained, on rockwork or on the level, *I. bakeriana* has, with me, invariably succumbed, sometimes after two or three years.—S. ARNOTT.

The Kafir Lily (*Schizostylis coccinea*).—This is one of the most brilliant of autumn-flowering plants, albeit, unless special means are taken to ensure success, it does not in many parts of England attain to anything like its full beauty before the arrival of frosts. To this end and because of its late flowering a warm position will prove helpful by promoting an earlier flowering and giving the shelter a selected site affords. A warm position, indeed, should mean much to this South African subject, and most gardeners will appreciate the fact. It should not be regarded, however, in conjunction therewith that in common with many South African bulbous plants the "Kafir Lily" prefers root dryness. In my experience it is the reverse,

Petasites japonica. (See page 637.)

rich and moist soils being much more to the liking of the plant. From the cultural point of view, too, experience has shown that an increased vigour and finer spikes result from growing the plants practically to single crowns, a method of cultivation which, in conjunction with annual lifting and resting, specialists have found to answer well with the *Montbretia*. Those who lift the plant for the greenhouse should rest their plants when flowering is past, keeping them as dry and cool as possible. No harm will ensue if they are dried off entirely; indeed, they will be safer so, and better fitted for a new season's work hereafter.—E. H. JENKINS.

Aster Amellus from seed.—One of the brightest groups in the garden a few weeks ago was a bed containing about fifty *Aster Amellus* seedlings. The flowers vary greatly in colour, shape, and size, all intermediate shades between pale lavender and deep violet; some are of the starry type, others have good broad petals. The earliest to flower was in full bloom by August 20th; the latest is still in flower.—L. B. W., in *Garden*.

THE WEEK'S WORK.

OPEN-AIR GARDENING.

IN BLOOM DECEMBER 6TH.—*Erica carnea*, *E. mediterranea hybrida*, *Polygala Chamæbuxus purpurea*, *Periwinkle*, *Aubrietias*, *Double Arabis*, *Winter Heliotrope*, *Andromeda floribunda*, *Genista tinctoria*, *Laurustinus*, *Jasminum nudiflorum*, *Escallonia montevidensis*, *Veronicas*.

WORK OF THE WEEK has been chiefly of a routine nature. Beds of choice varieties of Daffodils that were not lifted last autumn have been cleared of all weeds and a little bone-meal carefully pricked into the surface. Some long borders which are during the summer devoted to *Antirrhinums*, *Pentstemons*, half-hardy and tender annuals, etc., have been cleared of their occupants, and will be well manured and dug up roughly, burying the manure as deeply as possible. As espalier-trained fruit-trees are planted at the back of these borders, trenching cannot be practised. The work of cutting over the stems and generally tidying up herbaceous borders are being

their best they should be planted in large groups. *Erica mediterranea hybrida* has been in flower for several weeks. *E. carnea* and varieties have also commenced blooming. *E. lusitanica*, *E. arborea*, and *E. Veitchii* are now a mass of flower-buds, those of the first being already tinged with colour. *E. australis* is one of the prettiest of the Heaths, and should be included in every collection where it proves hardy. It thrives here in a sheltered position. The summer-flowering varieties include *E. ciliaris* (Dorset Heath), *E. cinerea*, *E. tetralix*, *E. vulgaris*, and their many fine varieties.

F. W. GALLOP.

Lilford Hall, Oundle, Northants.

SOUTHERN COUNTIES.

Birds.—Where tits, bullfinches, and sparrows are in the habit of attacking and disbudding Gooseberry and Currant bushes, as well as Plum-trees, the two former should be netted over and the latter syringed with something to render them distasteful. A specific can now be had for the purpose. Much good can also be done by looking round occasionally and shooting at the depredators as they leave the trees.

Pruning.—As the leaves are with few exceptions now off the trees, pruning can be commenced in earnest. Where much fruit is grown on walls, it is the rule to commence with Morello Cherries and finish with Peach-trees. By the adoption of this plan the former, which are usually grown on the north side of a wall, and, therefore, occupy the coldest position, can be pruned, nailed in, or tied, as the case may be, with greater comfort than when severe weather has to be encountered. Too much young wood is oftentimes laid in in the case of the Morello Cherry. This must now be thinned out sufficiently so that when nailing or tying is finished it will be equally distributed all over the tree and stand about 4 inches apart. The wood to be dispensed with may, if desired, be cut back to three buds to form spurs, but if the trees are in a healthy bearing condition spurs are a superfluity, and the spare wood is best cut clean out. In the case of old trees, shoots conveniently situated should be left to eventually replace branches which have become bare at the base and for some distance up. As such walls, owing to the aspect, often become coated over more or less with Moss in the course of time, advantage should be taken of the present opportunity to cleanse them. If the trees are partly liberated from the face of the wall and the branches held on one side, an old bass broom will usually suffice to free the surface of Moss. If this is followed up with a vigorous syringing, using soap-suds from the laundry when obtainable, the wall will remain clean for some time. Other fruits grown on north walls are—dessert Cherries, Plums, and Red Currants. The first, if properly attended to during the summer, require but little pruning now. Plums require the spur wood shortening to four or five buds; and that on Currants to three buds. The best way of training the last is as double or triple cordons.

French Beans.—A commencement in the forcing of these may now be made. If a continuous supply is required a sowing should be made every twelve or fourteen days. Seven-inch pots are a suitable size to use for early forcing, and these, after being crocked, should be about two-thirds filled with a mixture of loam, spent Mushroom manure, with a dash of bone-meal added. Seven to nine Beans of a forcing variety should be dibbled into each pot, and when up and the first pair of leaves has been made, reduce the plants to five in number and fill up the pots with the same kind of compost to within $\frac{1}{2}$ inch of the rims. The spray from worn-out Birch brooms forms a good support for the plants, which should be placed just within the rims and a few twigs in the centre. Until germination takes place, the pots can be stood anywhere, but if stood on a board laid on top of the hot-water pipes germination is considerably hastened. A Cucumber or forcing house is the best place to grow them in, as they require a temperature of not less than 65 degs. Their greatest enemy is red-spider, consequently, except when the plants are in flower, they must be syringed

continued during favourable weather. The stems are taken to the fire-heap, together with all weeds and leaves from the borders. The longer shoots of Roses have been shortened to keep the wind from loosening the plants at the roots. This same treatment is meted out to Hybrid Perpetuals, as well as to Teas, Hybrid Teas, and Hybrid Chinas. Soil is then heaped round the stems to a height of several inches. Some beds and borders planted with Hybrid Perpetuals and Hybrid Teas will be given a good mulch of partially decayed manure. An effort is now being made to finally deal with the leaves lying about in the grounds. These are being raked up and carted to where they are required for different purposes. Many of the gravel paths having become green and Mossy on the surface, these, when opportunity occurs, will be turned, levelled, and rolled. Provided the weather is favourable, the present is a suitable time to plant many of the hardy Heaths. By a careful selection of varieties, hardy Heaths may be had in flower all the year round. With the addition of a little peat they will thrive in most soils; in fact, on good loamy soils peat is not necessary. The dwarf sorts are splendid for edging and carpeting beds, but to see them at

with tepid water daily. When the pods begin to swell off mild doses of liquid-manure are then beneficial. In an ordinary way, from three to four dozen pots are a sufficient number to sow on each occasion.

Mustard and Cress.—From now and onwards a good supply must be kept up by sowing and raising both in heat in boxes at regular intervals. After germination takes place, the boxes are best moved into a cooler temperature.

Miscellaneous.—Advantage should be taken of wet days to get late-keeping Onions tied in bunches of five or six and slung on cords stretched at a convenient distance from the roof in the root store, when they will not only keep better, but for a much longer period than if left on the floor in layers of two or three thicknesses. Carrots, too, should be turned over with a view to ascertaining if any have decayed, and run over the same. Potatoes, both ware and seed tubers, should be frequently looked to, particularly the former, as they are not keeping any too well.

Late Peach-house.—The foliage has been retained by the trees for a longer period than usual, owing to lack of sun and fire heat in forwarding the ripening of both wood and leaves, especially on trees which are inclined to make gross growth. Now is the time to counteract such tendencies by a partial lifting of the roots by opening a trench some 5 feet or 6 feet distant from the stems and down to the drainage. This will allow for the soil being properly worked from among the roots up to a point some 3 feet away from the stem, which is generally as far as it is necessary to proceed with the lifting in such cases. All fibrous roots should be carefully preserved and the strong ones shortened back to where roots of a more fibrous nature branch off from them. In the refilling of the trench, some fresh fibrous loam and a liberal quantity of mortar rubbish should be mixed with the soil. Before finally finishing off give a good soaking of water, which settles the soil more effectually into place than any amount of treading. If the drainage material when reached is found to be in a bad condition it should be taken out and cleaned. A. W.

MIDLAND COUNTIES.

Second-early Peaches have been pruned and cleaned and the borders top-dressed ready for starting. Early in the New Year will be soon enough to start the trees in this house. As the buds are already swelling, the front ventilators will be closed if very cold winds prevail. The trees in the latest house are now receiving attention in the way of pruning and cleansing. All wood is well ripened and well set with flower-buds.

Orchard trees may be pruned during mild, open weather. When it is necessary to remove a large branch the wound should be covered with paint to keep out the wet and prevent decay. If frosty weather prevails old and useless fruit-trees may be grubbed, all prunings and refuse of every kind cleared up and conveyed to the fire heap. When the ground is frozen all wheeling of manure and soil on to fruit quarters should be done. No definite instructions as to the manuring of fruit-trees can be laid down, as the grower must decide what are the immediate requirements of the trees under his charge. Trees that carry average crops annually usually need some manurial assistance, especially those having a limited rooting space. I do not advise the use of fresh farmyard manure at this season for such as Apples, Pears, and Plums, this being best applied as a mulch in the spring. Thoroughly decomposed manure mixed with a quantity of old potting soil forms a good top-dressing. As a stimulant for wall trees I use a light dressing of soot and bone-meal, which usually keeps the trees in a healthy and fruitful condition. This is lightly pointed in with a fork after pruning and training are completed. Gooseberry and Currant bushes require rich farmyard manure, and this should be forked in as soon as the prunings have been cleared away. Fig-trees have been unfastened from the wall and the branches tied in bundles of a convenient size. This will allow

them to be readily protected with straw and mats during severe weather.

Early-flowering Gladioli.—The varieties comprising this section of Gladioli are especially suitable for pots, and whether grown as pot-plants or for cutting they are equally valuable during the spring and early summer. We are now potting up a quantity of these into 5-inch pots in a compost consisting of two parts good fibrous loam, one part leaf-soil, and a little coarse sand. In potting, a little sand is placed under each corm, putting from six to nine corms into each pot. When potting is completed, the pots are placed in a cool-frame, standing them on a bed of ashes, and covering over the top of the pots with sifted leaf-soil. As soon as growth is visible this covering must be removed or the plants will become very much weakened. When well rooted, the plants may be placed in very moderate heat, but no hard forcing must be attempted. Keep them well up to the light, and when the pots are well filled with roots and the plants in full growth, apply occasional waterings of weak liquid-manure to assist the plants to properly develop the flower-spikes.

Calanthes are coming into flower, and have been removed from the stove to an intermediate-house, where the blooms will last in good condition for a considerable time, and when cut will not fade so soon as when brought from a close, moist atmosphere. After the spikes are cut, the plants will be allowed a complete rest, placing them on a shelf near the roof-glass in a house where the temperature does not fall below 60 degs.

Asparagus.—Batches of roots should be placed in heat fortnightly throughout the winter if a constant supply is desired. This crop may be grown without fire-heat, provided a hotbed is available, with sufficient covering material to maintain a suitable temperature. Where it is intended to make new plantations of Asparagus next spring the trenching of the ground should be proceeded with as soon as it is in good working order. The situation chosen for Asparagus should be sheltered from west winds, which frequently cause serious damage during the autumn unless the shoots are well supported. The ground should be fully exposed to the sun, this being necessary for the production of early Asparagus. If the land is light and of an open character, ordinary trenching and a good manuring will suffice, but if the soil is heavy and cold, drainage must be provided and the ground trenched to a depth of 3 feet, leaving the bottom soil where it is, but incorporating with it a liberal quantity of manure and lime rubble. The top spit of soil from the next trench should then be placed over this and covered with a quantity of manure, which, in turn, will be covered with the second spit of soil from the same trench, and so on until the required breadth has been prepared.

Mushroom beds spawned six weeks ago are now in full bearing, a good supply being maintained by making successional beds about every five or six weeks. An atmospheric temperature of from 50 degs. to 55 degs. is maintained, the paths and walls being damped twice daily with tepid water. It is far better to err on the side of too little rather than too much heat, as by this means the quality of the Mushroom is superior and the beds continue to bear for a longer period.

Seakale is now plentiful, and a good supply will be maintained by placing in the Mushroom-house successional batches as required.

Early vegetables.—All leaves, especially Oak and Beech, are now being collected and stored for future use and are found most useful for making mild hotbeds for bringing on early vegetables. A pit is being prepared for the sowing of early Carrots. No fire heat is necessary for this crop, however severe the weather may be, provided a bed of fermenting material is placed in the pit. Leaves make the best hotbed for this purpose, the heat from them being more lasting and milder than when manure is employed. The leaves having been collected and allowed to remain for a fortnight, they are turned, placed in the pit, and trodden firmly, leaving the surface as even as possible. A 9-inch layer of soil is placed over the bed and made moderately firm and level previous to sowing the seed, which is done in drills

drawn at 4 inches apart. During severe frost a covering of mats sufficient to exclude frost will be placed over the glass. F. W. GALLOP.

SCOTLAND.

Pruning.—In the case of old trees, which in the open have filled their allotted space, the pruning is reduced to a minimum, more especially in the case of Apples and Pears. While one would like at times to allow more extension in such trees, it is not always feasible to do so, and they are, therefore, kept pretty well spurred in. The treatment year by year does not interfere with their cropping, which, after all, is the main thing. In the case of Plums, wherever it is at all practicable, the knife is used as sparingly as possible. I am convinced that when Plum-trees are too severely dealt with, not only is their cropping value diminished, but, in addition, the trees are more liable to "gumming," and to the dying back of branches of considerable size. Naturally, however, all weak and useless spray is cut out; but, as has been said, a too free use of the knife is not favoured. As regards a collection of young Apple-trees on dwarfing stocks, pyramids and standards, the pruning, of course, varies from that of older trees. Due attention must be given to the shape and balance of the tree—within moderate bounds, that is—for I would not cut out a promising shoot merely because it interfered with the symmetry of any tree if it were not very plainly superfluous. A point that sticklers for shapeliness very often appear to forget is that the first and chief end of a fruit-tree is to bear fruit; and if that purpose be attained shapeliness is only a secondary consideration. When, however, symmetry and fruitfulness can be combined, so much the better. At the present time all of us are on the outlook for devices to save time. During the pruning, instead of, as hitherto, allowing the prunings to fall to the ground to be raked up afterwards, a large hamper has been kept handy, the prunings collected in handfuls as they were cut, and dropped into the hamper. This has resulted in a considerable saving of time.

Figs in pots.—These, having now lost their foliage, have been top-dressed during the week. The usual practice is to repot at this time; but, owing to want of labour, top-dressing must suffice. The compost used consisted of well decayed old fibrous loam with a proportionate quantity of lime rubble and a dash of wood ashes.

Pot Vines, now quite dormant, were re-potted in the course of the week. These will either be kept in a cold-house or placed in a sheltered position out-of-doors for a short time until they are again required.

Fruit-trees in pots will be much better out-of-doors from now onwards. One point must be attended to, and that is, while frost will do no harm to the trees, it may damage the pots. Therefore, precautions must be taken to avert accidents. The pots, if assembled, can be covered with dry leaves, those of Beech preferably. The leaves can be kept from being blown about by high winds by putting a piece of wire-netting secured to a few posts round the trees. In addition, this covering of leaves will keep the balls in an even state of moisture throughout the winter.

Planting.—There will not during the present season be so much planting and transplanting as is usually the case. At the same time, there is always something to replace or to shift, and the work ought to be carried out at as early a date as possible. The stations ought to be prepared in advance, in order that no unnecessary delay may take place when the trees come to hand. In the event of frosty or very wet weather setting in when the plants arrive, they should not be unpacked. If placed in a cool, but frost-proof, shed they will be quite safe until conditions are suitable for putting them out.

Roses.—Climbing Roses have been attended to at a rather later date than usual owing to pressure in other directions. Of course, the current year's shoots were previously loosely tied in to prevent damage from winds; but it was not found possible to cut out the exhausted flowering wood. This has now been attended to, and these Roses retained. No

more wood ought to be retained than is absolutely necessary for the furnishing of arches, trellises, etc., for if too thickly crowded, the bloom is never so good, and the plants in summer, after their growth is completed, are apt to assume a tangled appearance.

Hardy-plant borders.—Cutting over of the ripened stems is being proceeded with as time allows. In the case of one long border, which is occupied by principally the taller and more robust-growing hardy plants—Delphiniums, Rudbeckias, Asters, Chrysanthemum maximum, Erigerons, Echinops, Eryngiums, and so forth—after cutting over was completed, and as very few bulbs find a place in the border, it was decided to fork the ground over. As all the plants grown are of a hungry nature, a good allowance of short, well-rotted manure was worked carefully in. Another border devoted to Phloxes and *Statice latifolia* was lightly pricked over, and the spaces between the clumps planted with Wallflowers. It is rather late for the latter work, but as the weather continues to be mild they will soon take hold.

Surplus Wallflowers are again being disposed of by planting them out in colonies in Grass. This is a very good way of utilising plants which would otherwise be thrown out. They are put out in a very rough-and-ready way, being notched into the turf with a spade exactly in the way that small forest trees are planted. As is only to be expected, a proportion of these Wallflowers does not succeed, but in ordinary years a very useful display is made in corners by plants which would very likely have been wasted.

Arum Lilies.—These are now making excellent growth, but as for a considerable time no pressing need exists for them they are being kept quite cool. In order, however, to maintain progress stimulants are being given fairly frequently. Such stimulants may very well be varied—for example, soot-water may be given on one occasion, and a chemical fertiliser in solution or diluted liquid from the tank on another. Arum Lilies are rather gross-feeding, and I think appreciate the tank liquid more than chemical substitutes, or even than soot-water, although the latter certainly gives tone alike to spathes and foliage.

Plants for spring flowering under glass.—I have previously referred to the value of certain hardy plants for the spring decoration of the greenhouse or conservatory, and those who may intend to give such a trial are reminded that potting-up must be carried out without delay. Good-sized pots—say, 9 inches in diameter—filled with good clumps of the yellow Day Lily (*Heimerocallis flava*) will make handsome specimens. Any of the Plantain Lilies in 5-inch or 6-inch pots are useful. Potsful of Montbretias are not without value, and, as everyone knows, *Spiraea* (*Hoteia*) japonica and Solomon's Seal force easily. Other instances of hardy plants which are equally useful will occur to those interested. It ought to be said that the *Heimerocallis flava* and Montbretias must not be subjected to a strong heat, but brought along quite coolly. As regards Funkias, they will stand stove heat. In the case of all hardy plants intended for pots, they must, of course, be allowed to become established before taking them inside. After potting, let them be stood under a wall or in a cold-frame for at least a fortnight before removing them under glass. I have accidentally omitted *Dielytra spectabilis*—one of the most graceful as well as one of the most accommodating of hardy plants for the purpose in view.

Under glass.—In wet weather the cleansing of fruit-houses, the cleaning and pruning of Vines, the washing and re-training of Peach-trees, and the usual routine work which are general at this time of the year may be attended to. No pains are too great and no time is badly spent which are devoted to such work. Clean trees and Vines and well washed houses will go far toward success in the season to come. If plants can possibly be kept out of Peach-houses and vineries it is a distinct gain, because the houses can be flung open by night and by day; and there is no need to apply the heat which is necessary when Chrysanthemums or other subjects have, perforce, to find accommodation in such. W. McGuffog.

Balmæ Gardens, Kirkcudbright.

ROYAL HORTICULTURAL SOCIETY.

DECEMBER 5th, 1916.

THE last fortnightly meeting of the year, while not making for great fulness, contained exhibits of sufficient merit to warrant the granting of two gold medals—one for the magnificent group of Orchids from Tunbridge Wells, the other for as fine a lot of Carnations as we have ever seen. These latter were from Haywards Heath. For the rest, there was much to admire and not a little to interest. For example, the collection of *Cypripediums* from Usk Priory, Monmouthshire, while containing novelties showing great advance, also demonstrated the highest cultural excellence; indeed, we have rarely seen such quality displayed. The new H.T. Rose C. E. Shea, shown by Mr. Elisha Hicks, revealed forcing properties of a very high order, its value, wedded to a variety possessing fragrance, good decorative form, and the ever-popular pink shade, unmistakable. Fletcher's new form of the Lawson Cypress, which gained an Award of Merit, also attracted considerable attention. It is possessed of a neat, elegant habit of growth.

CARNATIONS.

The magnificent collection of these from Messrs. Allwood Brothers, which gained a gold medal, was one of the features of the show. From a great centre of Wivelsfield White, one of the most popular, other varieties were arranged, usually three vases of each, a far more impressive way of showing them than in single vases. Thus disposed, and with two or three dozen blooms in each vase, a most imposing display resulted. May Day, Bishton Wonder, Nancy (pink), Destiny (cerise) (both novelties of high rank for the coming year), Benora, Wivelsfield Wonder (a new scarlet and white fancy after the last-named, but superior to it), Nora West (one of the finest things in the pink shades), with Salmon Enchantress and Enchantress Supreme were a few in a very beautiful lot. In a small group from Mr. J. C. Jenner, Sunstar (yellow) and White Enchantress were good. Messrs. William Cutbush and Sons had excellent stands of White Swan, White Enchantress, Champion (intense scarlet), and Carola (crimson), displaying them on a generous scale in conjunction with growing plants. In that from Messrs. Stuart Low and Co., a great vase of the new pink Alice stood out well, hardly less conspicuous being Belle of Washington (scarlet), Mrs. Myles Kennedy, Countess of Wilton (of cinnamon red tone), and Pink Sensation (very large). The new coppery-leaved Begonia Mrs. Petersen was also staged by this firm.

SHRUBS.

Excellent fruiting sprays of the Sea Buckthorn (*Hippophae rhamnoides*) were sent by Mr. A. Wright, Golf Grounds, Skegness. Messrs. R. F. Felton and Sons contributed a considerable assortment of cut shrubs, hardy and exotic, Eucalypti of sorts, *Hakea laurina*, a variety of Pittosporums including *P. Mayi*, *P. tenuifolium*, and *P. intermedium*, neat, glossy-leaved evergreens of high ornament in the cut state, and others. Two promising novelties came from Messrs. Fletcher Brothers—the dwarf Douglas Fir (*Abies Douglasi* Fletcheriana) (a pigmy suited to the rock gardener) and a new seedling form of Lawson's Cypress, *C. Lawsoniana Pottensi* (of neat, elegant growth). C. L. Fletcher and *Aucuba longifolia* Fletcheri were also shown. In a group from Mr. G. Reuthe, *Picea Breweriana*, *Juniperus sinensis prostrata aurea*, and *Olearia semi-dentata* were remarked, together with *Correa magnifica* (white), which in favoured places is hardy against a wall.

GREENHOUSE PLANTS.

The finer exhibit in this section was that of Chrysanthemums, the outstanding novelty Joan Maitland (a deep chestnut-bronze of the decorative class), which appealed to all. The plants were about 3 feet high, and were shown by Mr. G. Carpenter, West Hall Gardens, Byfleet. Messrs. W. Wells, Limited, exhibited the new pink Lady Stanley; Mollie Godfrey, Lily Neville (single white, very fine), Enfield White, and Mary (a miniature golden Pompon) being remarked in a large collection. An extensive collection of Hart's Tongue and other hardy Ferns, together with many greenhouse kinds, with Begonias, Cinerarias, and Cyclamens, were staged by Messrs. H. B. May and Sons.

ORCHIDS.

These were well shown generally, and one of the two Gold Medals awarded on the occasion was for a particularly good group from Tunbridge Wells. Its main feature was about six dozen flowering examples of *Cattleya Maggie Raphael alba*, each plant bearing a two or three flowered scape of white crimson-lipped flowers. Evidencing considerable variety, the pick of the group was undoubtedly those named Brilliantissima and Dreadnought, both of which, in addition to their fine proportions, were well marked. The novelty of outstanding merit in the group, however, was *Brasso-Lælio-Cattleya The Baroness*, Orchidhurst variety (of rich golden-yellow colour), whose rounded, well-goffered lip was very striking. This gained a First-class Certificate. *Cattleya Venus Queen of Yellows* was also a considerable attraction. Other novelties included *Odontioda Madeline* var. Black Prince and *Odontoglossum Doris*, Orchidhurst variety, each gaining a Preliminary Commendation Card. This fine lot came from Messrs. Armstrong and Brown. Very fine, too, was the collection of choice *Cypripediums* sent by Mr. R. Windsor Rickards, Usk Priory, Monmouthshire; indeed, it teemed of novelties and high-class varieties throughout—two of them, C. John Cypher (*C. Antinous* x. *C. Leanum*) and C. Chardwar, whose pouch and sepals are uniformly coloured a rich chestnut, the large dorsal sepal being freely spotted. C. Antinous (white and rich yellow), C. Curlew, C. Nydia (crimson and rose), and C. Pyramus splendens were all of high merit. The finer things in a group from Messrs. Charlesworth and Co. were *Brasso-Cattleya Queen Alexandra* (pure white and very handsome) and *Lælio-Cattleya Mita* (crushed strawberry colour and gold and crimson lip). *Lælio-Cattleya Serbia*, variety Bryndir (in mauve and crimson) was very good from Dr. Miguel Lacroze, Roehampton. Messrs. J. Cypher and Sons contributed a fine series of *Cypripediums*, the more conspicuous of which were C. Golden Fleece, C. Tityus, C. Charlesianum, C. Endora (a very dark variety), and the handsome Mrs. F. Wellesley. *Cymbidiums*, in conjunction with *Cypripediums*, were the chief of an exhibit from Messrs. Hassal and Co., the former including C. Motra (fawn and yellow) and the nearly white C. Pollux among others. Messrs. Flory and Black contributed *Cypripediums*, Stuart Low and Co. some very pretty *Sophro-Cattleyas*, Messrs. Sander and Sons having *Cymbidiums*, *Cattleyas*, and *Cypripediums*, their *Cattleya Snowflake* (handsome and pure) commanding attention at once.

ROSES.

A remarkable exhibit of the new pink H. T. Rose Charles E. Shea, which received the Gold Medal in June last from the National Rose Society, came from Mr. Elisha J. Hicks, the raiser. The flowers, two or three dozen of them on stems

2½ feet long, were the product of forced plants started in September last, at once a tribute to responsiveness and adaptability to winter forcing; for colour, form, fragrance, and value for early forcing this new Rose is already held in high esteem. To-day an enhanced value is added thereto by the demonstrated fact that it may be forced into flower in the very depths of the winter season.

FRUIT.

A capital dish of Serbian Quince was sent by Mr. W. North Ross, Cove House, Tiverton. The fruits were large and handsome, and of a golden-yellow colour. A handsome and shapely cooking Apple—which is not of bad eating quality also—named Nutfield Beauty, was shown by Mr. T. W. Herbert (gardener to Mr. J. T. Charlesworth, Nutfield Court, Redhill). It is of the largest size, yellow, faintly touched red on the sunny side, and very heavy. It did not, however, gain an award.

CORRESPONDENCE.

Questions.—*Queries and answers are inserted in GARDENING free of charge if correspondents follow these rules: All communications should be clearly written on one side of the paper only, and addressed to the EDITOR of GARDENING, 63, Lincoln's Inn Fields, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent each should be on a separate piece of paper, the name and address being added to each. As GARDENING has to be sent to press some days in advance of date, queries cannot always be replied to in the issue immediately following their receipt. We do not reply to queries by post.*

Naming plants.—*All who wish their plants to be rightly named should send fair examples of each—the stem, leaf, flower, or fruit. (Snippets of leaves and points of shoots are useless.) Not more than four plants should be sent in any one week by the same correspondent. Where more than one kind is sent they should be numbered. Of conifers the fruit should always be sent.*

Naming fruit.—*Several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruits for naming, these in many cases being unripe and otherwise poor. We can undertake to name only four varieties at a time.*

PLANTS AND FLOWERS.

Arum Lilies (L.).—At this time of year these require a temperature of about 45 degs. to 50 degs., keeping them well supplied with water. If in small pots liquid-manure will be beneficial to them. When they have done flowering in spring repot them or plant them out-of-doors in trenches of rich soil, lifting and potting again in September. Any good soil will do for the potting, but turfy-loam and rotten manure or leaf-mould make the best compost for them.

Growing Brugmansias (F.).—It is usual to cut Brugmansias back to the hard wood, or nearly so, in order to prevent their occupying too much space. During the winter when growth has ceased give them less water—only sufficient to keep the soil from getting too dry—and keep in an ordinary greenhouse. About the beginning of March shake the plants out and repot them, using as a compost one half good turfy loam, the other half leaf-mould and well-decayed manure, with some coarse river-sand. As the pots get filled with roots during the summer an occasional dose of liquid-manure is beneficial.

Nertera depressa (T. W.).—This does not need heat. In the southern counties it often succeeds in the open air, and is especially suited for a position in the rock garden. A partially shaded situation is advisable for this plant, which is easily propagated by the inser-

tion of young shoots in pans of sandy soil in gentle heat, covering with a bell-glass till established, when they may be potted off separately. A compost of loam, leaf-mould, and sand meets its requirements. Keep the Nertera in the shadiest part of your greenhouse, and remember that it only requires sufficient heat to exclude the frost.

Cutting back Fuchsias (Fuchsia).—The better way to treat the plants now would be to place them in the greenhouse, and there let them remain until January or later. They may receive just enough water at the roots to prevent their becoming quite dust-dry; but as long as there is any apparent trace of moisture in the soil water is not needed. They would do very well with the same treatment in any room from which frost is quite excluded. They may be cut back in March before they start into growth. When the shoots have just started to grow shake the plants out of the pots and place them in smaller ones, using moderately rich soil. The plants must not be watered too freely at first, but when well established they must not suffer in the least in this respect. When they have filled the small pots with roots they may be put into the pots in which you wish them to flower.

TREES AND SHRUBS.

Holly losing its leaves (Holly-tree).—In all probability the tree is suffering from dryness at the roots. Your only remedy is to mulch with a mixture of some fresh soil and well rotted farmyard manure, watering freely once or twice a week. If the Grass goes up to the bole of the tree, then the turf should be rolled back to, say, a distance of from 4 feet to 6 feet all round, the soil loosened and the mulch laid on, afterwards replacing the turf.

Pruning Pyrus japonica (Inquirer).—This will always flower in a far more satisfactory manner when allowed to grow naturally than it will if closely pruned. Such being the case, the plant should be cut back only as far as is absolutely necessary to keep it within the assigned bounds. No pruning to particular eyes or buds is required in this case, the main consideration being the space at disposal. At the same time any old or exhausted shoots should be cut out, as by so doing the young, clean growth upon which depends a good deal of the future display of bloom is thereby encouraged. A good time for carrying this out is directly the flowering season is over, as the specimen has then a long growing period before it.

FRUIT.

Vine on arch, pruning (E. W. C.).—Your best plan will be to unfasten the rods and cut the laterals back to, say, two or three eyes, at the same time cutting out any rods that are very weak, so as to encourage young shoots from the base. After it has been pruned the rods may be again fastened to the arch. The pruning may be done at once.

"Big-bud" on Black Currants (A. T.).—The "big-bud," as it is termed, is not a disease at all, but is due to the Black Currant gall-mite (Eriophyes Phytoptus). This has been known to scientists for a number of years, but it is within the last ten or fifteen years that it has worked such destruction in fruit plantations and gardens. The best remedial measures to combat this pest are to pick off every infested bud you can find now and burn them. Then in April and again the first week in May give the bushes a good dusting with a mixture of one part lime and two parts sulphur after having thoroughly damped them with a syringe. Also try syringing them weekly with Quassia extract both before they flower and after the fruit is set until the middle of June.

The various Loganberries (Novice).—These should be not less than 6 feet apart, as the plants grow very strongly. The long-summer growths should be tied up to stout stakes or trained to a wire fence in the same way as Raspberries. The shoots will reach a height of 8 feet or 10 feet. A warm, sunny position is best to enable the wood to get thoroughly ripened. In hot weather a mulch of manure should be placed over the roots. The old fruiting wood should be cut out every year to allow space for the new growths, which should in the winter be cut down to the height of the stakes or the wire fence. We should advise

you to cut down close to the ground the growths you refer to in order to encourage the establishing of the plants.

Shanked Grapes (J. E.).—That so many berries on your bunches of Grapes have failed to ripen and shrivelled is due to shanking. If you examine the stems of these berries you will find that they are brown and withered. The defect is due to several causes. First, the roots have gone deep into sour, poor soil, where they fail to find proper food. That is the common or chief cause, and to remedy it the border should have the top soil removed, the roots lifted, the bottom soil broken up, and have bone-dust, wood-ashes, and lime-rubbish mixed with it, then relaid shallow, and have a surface-coating of quite fresh soil, with which similar manures are mixed. Very heavy cropping and occasionally lack of moisture at the roots cause shanking.

VEGETABLES.

Vegetable refuse (G. J.). With regard to the disposal of all descriptions of vegetable garden refuse, it matters very little whether it is put into a broad, deep trench as collected to decay, or is put into a heap and occasionally turned to accelerate decay, and then used. It may be, however, most convenient for you, if you have the trench open, to put it into the trench at once, letting it lie all the winter to decay, then in the spring throwing in upon it some soil, mixing it with the refuse, then on that some manure and more soil, mixing that also. Such a trench should produce very large Celery and Leeks; but these may be coarse, and not so solid as less manured soil would give.

Vegetables for kitchen garden (Ignoramus). Beyond Cabbages and Lettuces, there is nothing else in the way of vegetables you can plant at the present time. You can, however, manure and dig the ground so that it will be in readiness for cropping in the spring, when early Potatoes, Peas, Broad Beans, and, in due course, Spinach, Radishes, Lettuces, Onions, Carrots of the Shorthorn type, Parsnips, and Globe Beet can be planted and sown. Seeing the garden is of limited area, you may wish to omit the first-named. In any case, you will not be able to devote a great deal of space to any one crop. Dwarf Beans, if you desire to grow them, should not be sown before the middle of April, and Runner Beans the first week in May. You may plant a few Cauliflowers the end of March, and as the ground becomes vacant set out Cabbage, Savoys, Cauliflowers, and Broccoli for autumn use, and Kale and winter Broccoli for spring cutting.

MISCELLANEOUS.

Liquid-manure (D.).—One of the best of all liquid-manures can be made with fresh horse-droppings. These should be put loosely into a coarse sack or canvas bag, tied at the mouth, and put into a tub of water—say, 1 bushel of droppings to 20 gallons of water. Give the bag a turn now and then to ensure that all the droppings therein are thoroughly saturated with water. The liquid will be ready for use after three days' soaking, and it should be diluted before use according to its strength. By adopting this plan the liquid is clear and free from impurities, and does not smell unpleasantly if made fresh frequently.

SHORT REPLIES.

Walsall.—It is immaterial. Either of the Vines will do on the east or west side. We do not understand what you mean by growing one Vine under the other, and shall be glad of a further explanation. In any case, we should prefer Foster's Seedling.—*E. P. S.*—Yes; you will find Hop-manure very good for Roses. The best way, we find, is to remove the soil to a depth of 2 inches or 3 inches round each plant and fill in with the manure, afterwards replacing the soil.

THE TRUE SPRING GARDEN.

If we think of the waste of means and time involved in the inartistic and stupid ways of spring flower gardening in the gardens about London and Paris for many years it may lead to dealing with the matter in a simpler way. The man with a town garden cannot help himself, he must bed out spring or summer; but in a country place the old way of digging up the flower garden twice a year was a stupid and costly way.

The lawn shown in the picture on page 653 between the house and the water was, a generation ago, without a trace of a spring flower in it. It is now every year as full of flowers as any alpine meadow, and has even a variety of early flowers. Very early in the year its beauty arrives with the Winter Aconite, the early Crocus, and so the story goes on for the following three months without any trouble to the gardener beyond the first planting of the bulbs. Let it be noted that no attention—manuring or special culture—is given; we simply put the roots into the turf, usually a few inches below the surface. The soil is a cool loam on sandstone, in which the Narcissi and some other things do well; but other bulbs do not do so well as they would in warmer soils.

A great point is only to use things that naturally bloom very early, and which in the mountains of Europe would be deeply embedded in snow when our green fields are a mass of Crocus, Snowdrop, and Snowflake, which flower much earlier than they do under deep snow. By confining early spring gardening to flowers that come early there is no limit to what may be used, except that it will depend on the nature of the soil. The reason for confining ourselves to early things like the Crocus is that the Grass of this field is mown for hay just as it would be grazed in the alpine meadows. As a rule, in this soil most plants increase and are happy, some less so than others, like the Crocus, that does not run about as in the chalky open soil. The blue Windflowers and the scarlet Windflower are among others that thrive and never go back. The only Windflower that fails in the turf is the Greek one, which probably does not part with its leaves so soon. The splendid scarlet Windflower does not thrive in the ordinary garden soil, but set in the turf in light and open groups is a brilliant success.

Any plants that keep their leaves all

through the summer should be omitted from the Grass where mowing is done twice a year; such plants are better in the copse or shrubbery.

This plan is well worth carrying out for the sake of its beauty alone; but that is not the only reason for it. One is that it leaves the flower garden proper free for its true object. If we have to drag up our flower garden twice every year we can never make a true garden of it. Roses and Lilies, Clematis, and many other beautiful things will not bear being disrooted every year. The value of the system is that it gives a real chance for a flower garden, in which more than half the things want permanence if to give a full result. Anyone can see the result of the opposite system at Kew or in the London parks, where there is a continual turning up and down of the beds. There are other real gains in the enduring way—first, that one may work at it on all fine days in autumn, winter, and spring, and get all ready for the final effort in planting out in early summer the tender plants essential for a good garden.

W. R.

NOTES OF THE WEEK.

Box edging in kitchen gardens.—"W." (page 615) is quite right in deprecating the use of Box edgings for kitchen gardens. Box looks well when properly kept and doing satisfactorily, but how often is this the case? Not very frequently, I fear, while the amount of labour it involves is very great. Then, as "W." points out, an edging should be one which gives no "shelter or shade to mouse, rat, or slug," and this cannot be said of Box.—S. M. D.

Cattle-poisoning at Ockham.—I am sending a piece of the Yew out of Ockham Park which is cut off one of the trees the cattle got at. I have never known any of our horses or cattle hurt by eating young green Yew, but should they get any old brown dead pieces, that, I know, is very bad, and generally fatal.—ANTHONY WATERER.

[The green Yew, we suppose it is, and it could not well be anything worse. A viper under a bush is not nearly so deadly as a green Yew within reach of horse or cow.—Ed.]

Chrysanthemum Joan Maitland.—This was the only new variety to gain an Award of Merit from the Royal Horticultural Society on December 5th, and if "bronzy-crimson" were permissible, so far as colours go, it would at least go some way to give an idea of a somewhat unusual

shade. As it was, I wrote it down "chestnut-bronze," since the colour came rather near to the rich reddish-crimson of the fruits of the Horse Chestnut. The colour appeared to attract everybody, there being three handsome flowers on a plant 3 feet high. It was shown by Mr. G. Carpenter, West Hall, Byfleet. The award was unanimous.—E. H. J.

Syringa Emodi.—"D.," who writes of *Syringa Emodi* on page 622, does not mention that the inflorescence of this species is not so graceful as that of the common Lilac and its varieties. It is a very distinct Lilac, seldom seen, but I do not care much for the flowers, which are not a good white. I have cultivated *S. Emodi* for twelve or thirteen years, but it is only within the last few years that it has bloomed well.—S. A.

Desfontainea spinosa.—Recently I saw a bush in fine flower in the gardens of Penrhyn Castle, near Bangor, within a few miles of the sea. It was some 6 feet high and 8 feet in diameter. The site was ideal, with a western aspect and sheltered from the east by a high wall some few yards away, the ground sloping gradually into a ravine. Thus the damp base, with abundance of exposure to the sun, appeared to favour healthy growth.—E. M.

Carnation Red Ensign.—This was much the best, in my opinion, of the three new Carnations gaining Awards of Merit at the Perpetual Carnation Show on December 6th last. A well-fashioned flower of the rosette type, large, good of stem, and with perfect calyx, cut flowers side by side with bushy, well-cultivated examples, also in bloom, were shown of what promises to be a most useful variety. The colour is light scarlet, a most effective shade under artificial light. It is an ideal habited sort.—E. H. JENKINS.

Chinese Primulas.—The highly interesting notes by "A Scottish Gardener" on this subject (page 624) lead me to remark upon the lessening cultivation of the older forms of *Primula sinensis*, so popular for very many years. The double varieties, long favoured, are rapidly going by the board (I do not regret this) and the small-flowered singles are favourites, although we still meet with a fair number of growers who cling to the large singles. *P. obconica* and *P. malacoides*, with *P. Forbesi*, have also done much to reduce the cultivation of *P. sinensis*.—S. M. D.

Scabiosa caucasica.—Where a difficulty is experienced in establishing bought in plants of this, as in "Byfleet's" case, seedlings should be used. Sow the seed in a cold frame in the latter part of the sum-

mer. Prick out the seedlings when strong enough, and finally pot them singly into large 60's, plunging them before winter sets in in ashes in a cold frame that should be kept freely aired. In this state they winter well, and, when planted out in early spring, grow straight away without any trouble or misgiving—such, at least, has been my experience after having failed with bought in plants.—C. T., *Highgate, N.*

The new forms of the Alpine Forest Heath (*Erica carnea*).—I have grown all these since they were first sent out, and have found that in some seasons certain varieties will bloom well and others poorly in the same soil. In other years those which generally flower freely may be disappointing. My poorest one this season is Mrs. S. Doncaster. Generally speaking, there is slightly less bloom than usual on my plants, which are grown in sandy loam. I attribute this to the wet season, the rainfall having been greatly in excess of that of most years. Regarding the remark of "N. L." about the white variety of *E. carnea* not blooming so freely as the type, this has its flowers more widely scattered along the branches and not in a cluster, as is the case with *E. carnea*.—S. ANNOTT.

Chrysanthemum Progne.—This bright amaranth-purple coloured flower used to be much grown, and was appreciated for the sake of the pleasing violet-like fragrance of the blossoms. It seems to have almost, if not quite, disappeared, though its perfume would suggest whether it might not with advantage be employed as a seed-bearer in the production of new varieties. I was reminded of Progne by seeing the name in a list of "New and Beautiful Rare Plants," offered by William Rollison and Sons, of Tooting, for the spring of 1858, in which it was quoted at the price of half-a-guinea each. Another variety, at half the price, was Julie Lagravere. While all the others in the above-mentioned list soon disappeared, the two herein named held their own for many years.—W. T.

Felicia petiolaris.—This was planted in the spring of 1915, and flowered freely in September and October. A slight protection—fir branches, etc.—was given during the winter. Whenever the trailing growths touch the ground they root. From February to June of this year there were quantities of flowers. The plant is now 3 feet across and 2 feet high. On December 9th a number of flower-buds were formed. These will open in a few days, unless there is hard frost. The foliage is very pretty, and the flowers are like tiny Asters, pink and white. In May last I put a small rootlet into a 6-inch pot, and have kept it in the greenhouse. Two or three flowers opened in June, and at present there is no sign of more. This plant is now 18 inches across, and the trailers try to root on the pavement. I should like to know whether this *Felicia* usually behaves as I have described. In two other gardens no flowers have ever appeared.—E. CHARLES BUXTON, *Cood Derw, Bettys-y-Cood*.

Sparmannia africana.—Complaints are sometimes made that this does not flower so freely as might be wished. This is frequently due to its being treated too liberally, the result being shown in its rank growth and poor display of blossoms. It is best to allow the plants to become quite pot-bound, and to supply the necessary stimulant either in the shape of liquid-manure or one of the many plant foods now available. If the plants have been grown on in the greenhouse they should, soon after midsummer, be stood outside in a spot fully exposed to light and air. This ensures a thorough ripening of the wood and consequent formation of

flower-buds. During the time they are out-of-doors the plants must not be neglected for want of water, otherwise the leaves will turn yellow, and their ornamental qualities be, therefore, much impaired. Should this happen, an occasional dose of soot-water will put matters right. Care must, of course, be taken to remove the plants under cover before the nights get too cold, otherwise the embryo blossoms may be injured. Large specimens may, as standards or bushes, be grown in pots or tubs, and in this way the white flowers, with their brush-like mass of stamens, gold and purple in colour, form a delightful mid-winter feature. Smaller plants in 5-inch pots will also flower freely.—K. R. W.

Anomatheca cruenta.—This Cape bulb is not much grown by the amateur or gardener. It is a capital subject for the warmer districts of the United Kingdom. In these it is hardy, but in other parts it is not to be relied upon. In such cases it is safer to lift the bulbs in autumn as soon as the foliage becomes yellow, and store them in a frost-proof place. It is not generally known that it is much brighter and more effective in shade than in sun. The late Mr. F. W. Burbidge pointed this out to me in the Trinity College Botanic Garden, over which he presided so ably. In cold districts planting should be performed about March. *Anomatheca cruenta* makes a good plant for pots for the conservatory or greenhouse. One bulb will be enough for a small pot, but about three in a 6-inch one will give a fine display. It is a beautiful plant 6 inches to 12 inches high, with a spike of rather starry flowers of red tinged with scarlet, and with a deep blotch on the three lower segments. A rather sandy soil suits it well.—S. ANNOTT.

The pergola and its proportions.—A lady told me the other day that she was worried by the climbers on the pergola interfering with her hat, feathers, etc. That may happen with the ill-designed and worse built pergola of the British garden. Knowing Sir Ernest George had an important one in hand I wrote to him as to its proportions, and here is his reply:—

In the scheme sent to you the roof is 11 feet or 12 feet high. The height seemed necessary in relation to the length and width of the structure, and for the proportion of the columns. I have only wondered if this was inconveniently high for the planting and covering of the pergola. Certainly the lady's bonnet and feathers should be free of any hanging tendrils. The width between pillars is about 10 feet. The length is about 230 feet.

No fear of the height being too great for the climbers, *Wistaria*, *Vine*, etc., often growing 50 feet or more high. One of the real gains of the pergola is that it allows of the noble growth of all the beautiful climbing plants in a far more natural way than the old crucifixion on walls with nails and shreds.

Shortia galacifolia.—I do not know whether of this popular North Carolina subject there are forms which rarely give good leaf colour, no matter what the circumstances attending its cultivation, but it would appear that some plants colour only slightly, while others are of exceptional brilliance and very striking during autumn and winter. Some growers, I find, regard exceptional leaf brilliance as a decadent sign, others, taking an opposite view and approving of it, regard it as the product of full exposure. I have it, however, at the moment brilliantly coloured and in the best of health in a position where it has hardly experienced a gleam of sunshine this year. The plants are in a mixture of about equal parts peat and leaf-

mould, with a little sand and finely-powdered brick, the last being added from a personal fancy I have for the material rather than as a considered necessity. Anyway, the plants have done well in it, and success is the best test. By the side of the above and under precisely similar conditions *S. uniflora grandiflora*, from Japan, while in excellent health, has pale green leaves. If anything, this latter is the more vigorous, though I do not remember noticing that at any time it colours so well as the first-named. In the circumstances I am looking forward with interest to their flowering next spring. What is the experience of others? One prefers flower to leaf beauty, naturally, in such a plant, but if, while retaining health, both may be found possible, a dual pleasure will be afforded to many.—E. H. JENKINS.

Cotoneaster frigidus.—I quite agree with all that Mr. Jenkins writes regarding the attractiveness of this species of *Cotoneaster*. I saw a number of trees and bushes of it heavily laden with fruit in a plantation bordering the public road at Alsop-en-le-Dale, in Derbyshire, in the latter part of September. At the time I was puzzled to know what it could be, but found out a week later, when in London, that it was the above-named species of *Cotoneaster*. As seen growing, I was greatly impressed with its beauty, and then and there made a mental note to include it when the time arrived for the planting of ornamental shrubs.—A. W.

A note from Tipperary.—In spite of an excessively wet October and November, an unusual number of shrubs was in blossom late in the year. On November 20th the following kinds were in flower:—*Spiraeas*, *Escallonias* (several), *Erica codonodes*, *St. Dabec's Heath*, *Fuchsias*, *Laurustinus*, *Salvia Grahams*, *Sutherlandia frutescens*, *Abutilon vexillarium*, *Solanum jasminoides*, *Myrtle*, *Ceanothus Indigo*, *Veronicas*, *Jasminum nudiflorum*, *Hydrangeas*, *Tree Mallows*, *Eupatorium Weinmannianum*, *Coronilla glauca*, *Berberidopsis corallina*, *Abelia floribunda*, *Medicago arborea*, *Pittosporum Tobira*, *Buddleia asiatica*, *Leptospermum bullatum*.—P. H., *Co. Tipperary*.

Carnation Beacon.—For those who keep their eyes open there are object-lessons not to be ignored in the way those who obtain their living—or a portion of it, at least—out of growing Carnations cling to well-tried varieties. In the above-named variety one of these object-lessons is obvious. As a scarlet "it takes some beating" the largest growers say, and the statement is made on the strength of an experience which is nothing if not progressive. Conservativeness as applied to flower growing has no standing, every grower being out for the best and most productive sorts of the colours chiefly in demand. And the sorts most approved by the florists should be good enough for all so far as standard varieties go. It is these facts which bring Beacon to-day, as it has been for several years past, into the category of a virtually indispensable scarlet. It is not that it is perfect—that *Carnation* has yet to be raised—but that it possesses many good qualities—rich and consistent colour, that continuity of growth which is the forerunner of perpetual flowering, and, while not of the largest size, a cropper of no small importance. Loss of crop owing to blind or slaty-coloured flowers is not large in Beacon, and the less where intelligent cultivation prevails. Beacon may still be improved so far as strength of stem and size of bloom go, and with these, wedded to the variety as we know it to-day, a scarlet approximating to the ideal would be very near at hand.—E. H. JENKINS.

FRUIT.

PLANTING FRUIT-TREES.

TREES of all sorts will now be in the best condition for moving, for, with their roots lifted in good condition and transferred to fresh soil without being allowed to dry up in the interval, they will immediately begin to push forth fibrous roots that will enable the trees to become at least semi-established before winter has set in. Trees planted in autumn, and well looked after as regards mulching and watering later on, if need be, will hardly feel the check of removal and may be allowed to carry a crop next year, a thing that it would be unwise to allow winter or spring planted trees to do. Planting from home-raised stock need not be further delayed, and the getting of these out of hand will help matters forward considerably and leave all available labour open to deal with bought-in stock in an expeditious manner when it arrives.

In taking out the stations for planting,

ramming the soil immediately round the roots with a rammer or from treading it. These operations should be left until sufficient soil to protect the roots from injury by direct contact with rammer or boot has been added. If the roots are too plentiful to allow the soil to be worked in among them in a satisfactory manner by the hand, then by all means use water to wash it in, and leave the filling up and finishing off until another day. Of course, a little water is of no use. It should be a thorough soaking, sufficient to melt the particles of soil and cause them to settle down close together.

PEAR PASSE COLMAR.

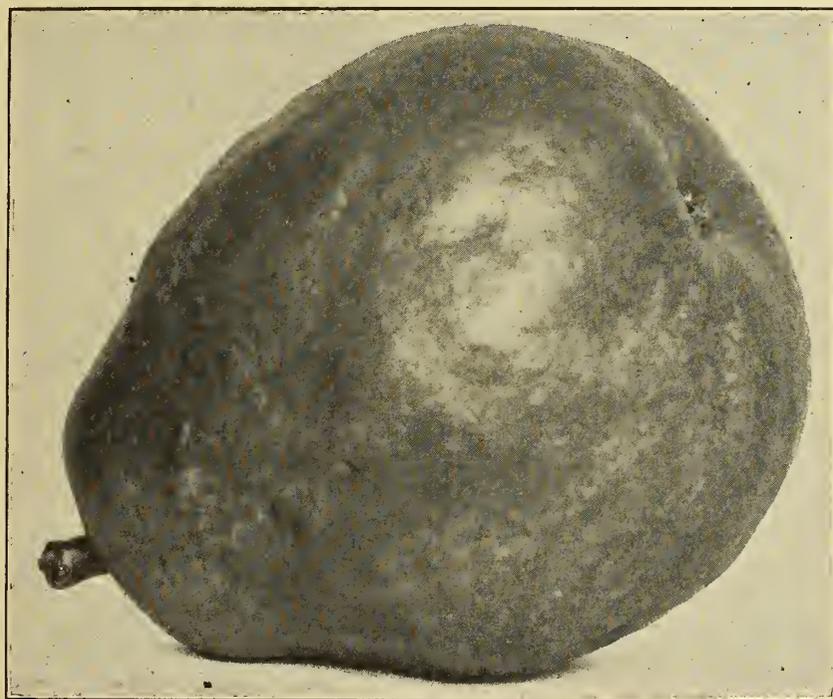

This Pear varies in quality, this largely depending on the soil in which the trees are planted, the best fruits coming from those on a warm soil. In the Royal Horticultural Society's gardens at Chiswick this Pear was grown as a pyramid, and also cordon-trained on a wall. In both cases the quality was excellent, due, in great measure, to the soil and also the fact that

variably succeeding, and upon some trees he has worked as many as five different varieties. Nor does Mr. Halliday confine himself to Apples. Standard Plums, such as Coe's Golden Drop and Jefferson, claim his attention, and in his modest glasshouse he grows the most wonderful mixture of plants I have ever seen. Cacti, Hydrangeas, Ferns—mostly raised from spores—Begonias, Chrysanthemums, Pelargoniums, and Fuchsias all find a place. On the wall—a lean-to structure—is a fine piece of Maréchal Niel Rose, while on the glass front there are a couple of Black Hamburgh Vines, which, I was told, ripened a fairly good crop. The mixture, no doubt, would appal the orthodox gardener, but every plant in the house was clean, and the picture of health.—W. McG.

NOTES ON PRUNING.

THERE is no necessity to wait until the leaves have fallen ere a start be made, for by the time these lines are in print all foliage will be showing signs that it has performed its necessary task. While advocating an early start, a little discretion must be used by the pruner in attending to those trees that lose their foliage first, and getting the work forward before too severe weather sets in. Those trees occupying north sites should be the first to claim attention. The reason for attending to north walls first has a twofold object—the work can be more expeditiously carried out, and the men engaged in the operation while the weather remains fairly mild are more comfortable. Here will be found Morello Cherries, Gooseberries, and oftentimes Currants, especially red, all of which can now be pruned and retrained if thought necessary. Taking Cherries, many unnailed the trees, and as these often lose a branch it is necessary to do so. This will give an opportunity to thoroughly cleanse the tree as well as the wall. The latter, if it cannot be fresh coloured, should have the garden engine or the hose laid on, and be well washed down after old ties, shreds, etc., are removed. Next see to the trees, and either thoroughly syringe or paint them with an insecticide strong enough to destroy aphides, red-spider, or any other enemy of the host a gardener has to grapple with, before attempting to replace the shoots. As regards pruning this Cherry, it is known by all who have had a few years' experience in the general cultivation of fruit, that it bears principally upon wood made this season, so that enough shoots must be retained for next year's supply of blossom, if not of fruit. Are not Morellos usually trained far too thickly? At any rate, I think that they are, and that much better crops would be had if more space were allowed between the current year's wood. The trainer should bear in mind when nailing in the shoots to the wall that many more will require space in July or early August, therefore 4 inches should intervene between each young growth, so that one at its base can be retained for the following season's supply, as above stated. These said shoots should be laid in their full length, and unless there is a scarcity of young wood it may be shortened to where required. Fan-shape is the best mode of training all stone fruits, as it is much easier to replace a branch should one die off.

It has been said the Cherry bears chiefly on the preceding year's wood, but it also bears upon spur growths, and it must be the pruner's aim to encourage a moderate number (not enough to crowd each other), or the older wood presents a naked appearance. Therefore, all young shoots, evenly distributed and not required for training in, should be cut back to within

Pear Passe Colmar.

make sure that the bottom is made firm so that there shall be little or no sinking, and allow for each tree only sufficient depth to admit the roots so that the upper ones may be quite near the surface and, above all, see that the stem is buried no lower than it has been previously. On heavy and damp soils elevate each tree on a slight mound, as the depressions between the mounds act as surface-drains and the feeding roots are kept in a healthier state than they would be if planted on the level. On the other hand, in very light soils any such elevation would be a mistake, as in dry seasons the roots would get dried up. If the trees to be planted are of a size to make staking necessary, the stakes should be driven down into the holes before the trees are planted, as this will prevent all fear of driving the stake on to any of the roots and injuring them. Cut away all damaged portions of roots, severing them at the point of junction with a branch root wherever possible, then the cut surface will heal over instead of dying back. Work some of the best soil well in among the roots, so that no hollows or badly filled crevices may be left, but refrain from

the trees when the fruits were swelling were freely mulched with manure and abundance of water given. The fruits are green at first, but as they ripen they take on a dull lemon colour with a tinge of brownish-red on the sunny side. Its season is from November to the middle of December, though if trees are grown in different aspects fruits may be had up to the end of the year. The flesh is yellowish, very juicy and melting. The growth is moderate and the tree can thus be depended on for regularity of bearing. T.

An amateur's garden.—It was well said recently, by a writer in GARDENING ILLUSTRATED, that size in a garden is not everything, and quite as much pleasure may be had from a moderate area well attended to as from a larger extent of ground cultivated in a haphazard way. This was borne in on me the other day during a visit to Mr. John Halliday's garden at Greystone, Kirkcudbright. Mr. Halliday is a most enthusiastic gardener, and is more especially interested in Apples—particularly in grafting. His success is wonderful, every graft which he uses in-

two eyes of their origin, at the same time cutting away altogether any that have got far away from the surface of the wall, for they not only look unsightly, but they do not, as a rule, set their fruit so well as when close in. Gooseberries, also Currants, need like treatment, as both fruit principally upon spur growth, though a young shoot for extension, or to take the place of an exhausted branch, must occasionally be laid in, as after a few years the old ones produce small fruit, and get in a similar plight to the Cherry. Many of our best kitchen Plums also occupy northern positions, and may receive attention afterwards, these fruiting mostly on the spurs. No reason can, however, be assigned why a convenient shoot here and there should not be laid in where space affords or where an old branch can be covered, so that few bare places on the wall can be noted. A. G.

WATERING FRUIT-TREES IN AUTUMN.

If there is one point on which growers agree more than on another it is on the importance of the thorough ripening of the wood in autumn. It is a good omen to see the leaves change to a rich golden colour and drop off naturally, leaving plump buds behind. Drying off or forcing to rest from lack of moisture is a most dangerous proceeding, and many a crop of fruit is thus wrecked, even while yet in its embryo state. The roots of fruit-trees are never wholly at rest, and can no more be safely left without a supply of soluble food than can any living thing without feeling its effects, and not only feeling them, but showing them the following season. Let anyone take the trouble to examine fruit-tree borders either under glass or in the open, in the months of August and September, when all the roots have been actively draining them of moisture, and when they have been subjected to the still larger drain by evaporation; the work of watering must have been more attentively carried out than I have generally found it to be, if a thorough good deluging would not prove more conducive to the proper ripening of the wood and plumping up of the buds than any amount of drying off. If there be green or immature wood in any case, I have generally found it in trees that have been checked by drought from perfecting their growth until late in the season, when the moisture from autumn rains has started them afresh, clearly indicating that growth was only arrested, but not completed.

If amateurs would only consider that fruit-trees under glass are solely dependent on the supplies of moisture given them by means of the hose or the watering-pot, and that keeping their trees on what is called the "dry side" is dangerous at any time, we should have fewer complaints of Peach buds falling off and the buds of Vines refusing to break regularly. These things only occur when the rains are intercepted by a glass roof, and where no means are taken to supply the deficiency of moisture. This is the time when the roots of fruit-trees, bushes, or whatever other term they may go by are in active search of food to fill up the fruit buds of another year. Do not, therefore, imagine that, because the old leaves are putting on their autumnal tints, the roots are dormant; for on examination they will be found more active than when the blossom is expanding in spring. Therefore, to curtail their supply of root moisture is certain to throw the whole constitution of the tree out of gear. Let anyone take the trouble to examine a Gooseberry or Currant-bush at this time and note how the fruit buds are swelling up. But although the autumn

rains are filling the buds, ready for the first breath of spring to awaken them into action, there is no fear of their anticipating that season unless they have been arrested in growth through lack of moisture. Those who have fruit-tree borders would not think of keeping them on the "dry side" when the crop was swelling; and yet next year's crop is equally dependent on a supply of root moisture now, even though there is not much visible sign of activity. T.

GOOSEBERRIES FOR HEDGES.

THOSE whose gardens run by the side of roads are often troubled by fowls, dogs, and the like if the hedges have been neglected in the early stages of growth or are composed of unsuitable plants. In this neighbourhood, for instance, there would seem to have been a craze for planting Elder—certainly not a fence plant. Having had experience of this, and not caring to go to the expense of uprooting the Elder, I decided to fill the gaps on the inner side with some strong, healthy, young Gooseberry plants. The ground—a good, heavy loam—is, naturally, well adapted for fruit-trees, so it was only necessary to turn it up deeply and add a little good manure to give the trees a start and ensure plenty of annual growth. A few iron rods were inserted at intervals and some of the shoots fastened from the ground upwards, crossing them in different directions so as to secure something of a fence from the start. The hedge now, at the expiration of three seasons' growth, presents quite an impenetrable barrier to anything outside, and I am now drawing some of the stronger shoots upwards and lacing them across other rods so as to have an inner hedge of Gooseberries about 4 feet in height. Of course, there are occasional places where toll is laid on them from the outside, but this is only a trifling matter, and no damage is effected from the hedge standpoint.

When growing Gooseberries in this way one does not get or expect high-class fruit, but an abundant supply is provided for picking green and bottling. Those who care to experiment on a Gooseberry hedge should choose strong-growing kinds of fairly erect as opposed to a drooping habit, especially if a height of 3 feet or 4 feet of hedge is required. A still more impenetrable thicket can be obtained (if one can afford to wait for it) by inserting cuttings in the gaps, leaving all the buds intact, although with a lot of wood springing from the base the top growth is, naturally, not so luxuriant, and probably it is best to start with young, clean-stemmed trees.

Hardwick.

E. B. S.

STRAWBERRIES.

WITH the exception of those recently planted, all beds should be manured the first opportunity, and if, when this is done, the ground does not happen to be frozen sufficiently firm to bear the weight of the barrows without cutting into the soil, boards should be laid between the rows to run them on. If very weedy, the ground should be hoed and the weeds raked off beforehand, but if it is fairly clean the few weeds that are present can be turned in when pointing takes place after spreading the manure. The manure for this purpose should be the best obtainable, and the quantity to apply governed by the age of the plants and the quality of the soil. As a rule, two-year-old plants and upwards are generally benefited by being given a good dressing, which, if applied now and just buried beneath the surface, quickly becomes available as plant food. Deep digging is not advocated, as great numbers of roots are destroyed as a result, but if the soil is

moved to a depth of 3 inches or 4 inches only and placed on top of the manure as the pointing proceeds no harm in this direction will ensue. If manure cannot be afforded, artificials should be used instead. These are best applied early in the year. If means are at command for making a good quantity of wood ashes by the charring of refuse wood, preferably that in a green state, these may be applied at once, and, on account of the potash they contain, do an infinite amount of good. This, though a rough-and-ready method, is one way of imparting potash to the soil now that it is unprocurable. Plants set out last August and September should be looked over, and if any have been lifted by frost, make them firm again by treading the soil well round the collars. Remove weeds and late-pushed-out runners at the same time. K. P.

Root-pruning fruit-trees.—There can be no doubt but that root-pruning is a very great help to fertility in the case of trees whose roots have got out of bounds and, possibly, into the crude and ungenial subsoil. The well-doing of trees is not regulated by the immense spread of root which some of them have, but by the number of feeding roots which can be produced in a given space where food is plentiful, and root-pruning is one of the greatest possible aids in the production of such roots. Some people are very particular to carefully lift and relay every root that can possibly be saved, but it has been proved over and over again that, provided root-pruning be done properly—i.e., each root severed with a clean cut to a point close to the junction of a less root and not too close home to the bole of the tree—the loss of a portion of each root is immaterial, and the work is greatly facilitated by getting rid of the trouble of relaying the uncovered portions. In this matter I make a great distinction between the trees to be simply root-pruned and those to be replanted. In the latter case I carefully try and preserve every possible bit of root, as I know that all will be required to assist in re-establishing the tree, but the case is very different where no lifting is intended, as the roots are then ready to produce feeders, and plenty of them, immediately. When root-pruning, a good broad trench should be taken out round the tree at a distance from the bole corresponding with the spread of the branches, or nearly so, and if there is a suspicion of gross growth and unfruitfulness proceeding from one or more tap-roots, the ball should be undermined and such roots severed, for if they are allowed to remain the severance of any spreading roots will be of little avail in inducing a more fruitful tendency. When refilling the trench be careful to incorporate with the soil a plentiful supply of mortar rubbish and burnt earth or wood-ashes. If some good turfy loam can be added, so much the better, but whatever may be used should be well trodden or rammed home, as firmness in fruit borders is a very desirable condition. If on examination the subsoil is found to get wet or sour, the excavation made should go to a depth of from 30 inches to 36 inches and the bottom be filled up with brick-rubble several inches in depth before replacing the soil.—T.

The folly of growing Crab Apples.—One cannot too often repeat the statement that it is folly to grow sour, ill-conditioned Crabs when it is possible to produce really good, wholesome Apples. Some of the best dietetic experts condemn manufactured sugar as unwholesome. Now, we may not object to a little of it, but the quantities that have to be added to these Crabs at once condemn their use as a rational food. People tell us that the blacks who chew

sugar-cane extensively are very healthy, but in chewing the cane they get all the juice, which contains many elements absent from table sugar. We may be quite sure that it is best to get our sugar as it is naturally combined in first-class fruit. Again, where is the economy in buying or

TREES AND SHRUBS.

THE PORTUGUESE HEATH.

We have so often written about this beautiful Heath that, perhaps, it is unnecessary to say much more about it now, save that

the flowers separates it from most other things of the season. It is, indeed, a precious gain to our island garden flora.

W.

TREES AND SHRUBS CERTIFICATED IN 1916.

The different subjects so honoured show a considerable increase on the preceding year, when no first-class certificates were given and only 18 awards of merit. In 1916 five first-class certificates and 22 awards of merit were made by the Floral Committee. They were as follows:—

ABIES BRACTEATA.—This Silver Fir is a native of California, from whence it was introduced by William Lobb when travelling in North America. It forms a very handsome tree, but, unfortunately, it is particularly liable to be injured by spring frosts. The specific name is derived from the long terminations of the bracts, which give to the cones quite a distinct appearance. First-class Certificate, January 11th.

BERBERIS JAPONICA BEALEI.—A well-known member of the pinnate-leaved section of Barberries, which is often regarded as a true species under the name of *B. Bealei*. It is somewhat more tender than the typical *B. japonica*, and the lemon-yellow blossoms are borne in spring. Award of Merit, February 8th.

BERBERIS JAPONICA HYEMALIS.—Remarkable from the fact that it flowers from late autumn till the spring, a very desirable feature. Award of Merit, February 8th.

BERBERIS RUBROSTILLA.—An accidental hybrid, which originated in the Wisley Gardens. Its general appearance would suggest *B. Wilsonae* as one of the parents. The new comer forms a graceful-habited, deciduous shrub, whose most attractive stage is when laden with its brilliant coral-red fruits. The entire plant is spiny. First-class Certificate, November 7th.

BERBERIS SARGENTIANA.—A beautiful evergreen species, native of China. Its nearest affinity is with the Himalayan *B. Wallichiana*. Though an evergreen, most of the leaves in autumn take on various shades of red and bronze, though some remain quite green. The straw-coloured spines form a very notable feature, but the small, blackish-purple berries are not particularly attractive. It was given an Award of Merit in 1915. First-class Certificate, November 7th.

CLEMATIS CRIMSON KING.—The flowers of this garden variety are, when first expanded, of a kind of crimson tint, but change to more of a wine-red. Award of Merit, May 23rd.

COTONEASTER HORIZONTALIS PURPUSILLA.—A variety of the well-known *C. horizontalis*, which differs from the type principally in its smaller leaves. Award of Merit, January 11th.

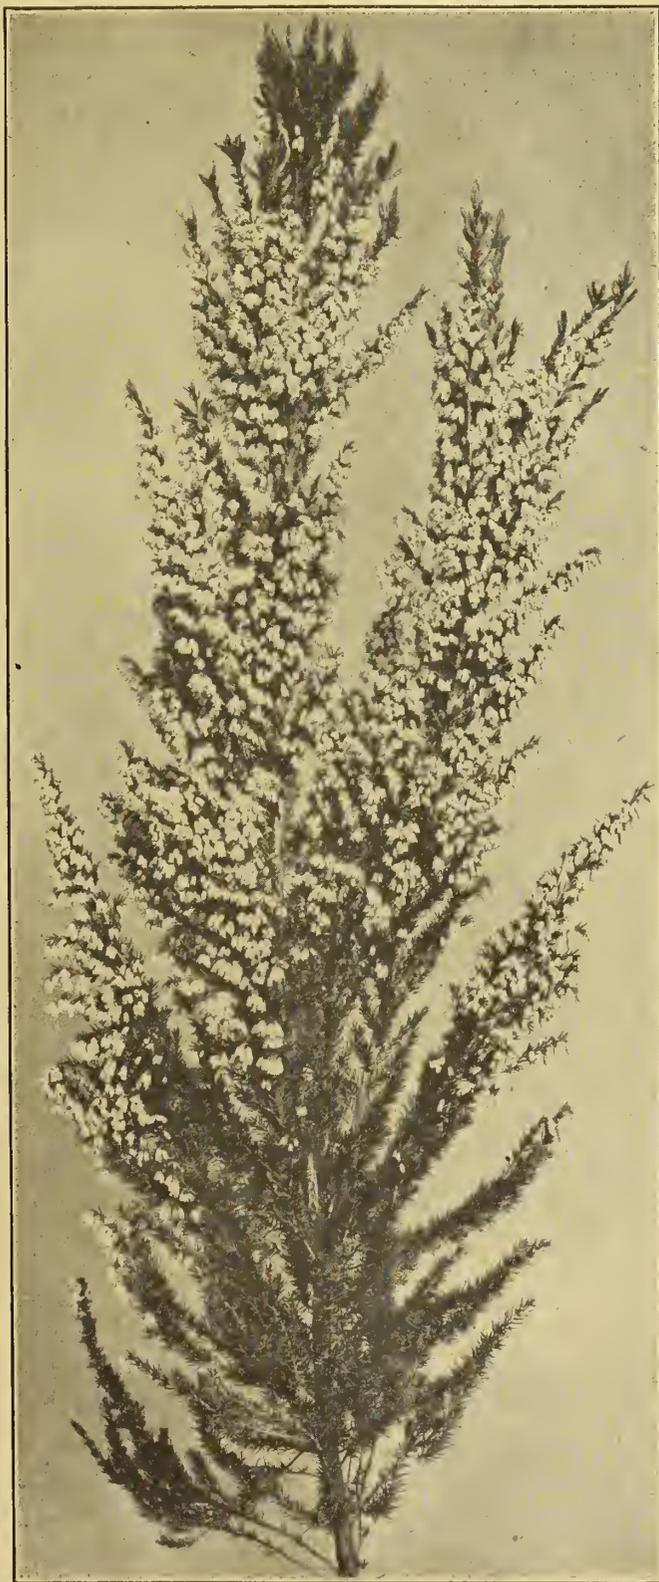

CUPRESSUS LAWSONIANA POTENSI.—A seedling variety of Lawson's Cypress. The new-comer, which is of a pleasing glaucous hue, is of a columnar habit of growth. Award of Merit, December 5th.

DAPHNE CNEORUM VERLOI.—This variety of the Garland-flower has longer leaves than the species, while the blossoms are borne in loose clusters. It is also said to be somewhat later in flowering than the type. Award of Merit, May 16th.

DEUTZIA CRENATA MAGNIFICA.—One of the hybrids raised by M. Lemoine, of Nancy, between *D. crenata* and *D. Vilmorenae*. The flowers of the new-comer are double, pure white, and borne in great profusion. Award of Merit, June 20th.

ESCALONIA DONARD SEEDLING.—A very promising Escallonia, obtained by the crossing of *E. Philippiana* and *E. Langleyensis*. It has large bluish-coloured flowers. Award of Merit, July 4th.

EUONYMUS LATIFOLIUS.—This is a well-

Spray of the Portuguese Heath.

growing fruit that one cannot eat without first buying an equal weight of sugar to enable us to tolerate it? As I have said before, why not grow our own sugar in the fruit itself? I am quite sure that natural methods are the best.—W. J. FARMER in *The Garden*.

this mild season has induced in it a charming way of beginning to flower early in the winter. In cold years it does not begin to flower until early in the spring. In some parts of our islands it is so happy that it naturalises itself, as in Dorset, and in my own case I find it does so. The blush on

known shrub that has been grown in this country for nearly a couple of centuries. It is a native of Europe, and when in good condition forms quite a small tree. Nearly related to our common Spindle-tree, it, like that well-known kind, depends for its beauty upon its bright rosy-red capsules and orange-coloured fruits. Award of Merit, September 26th.

LEPTOSPERMUM DONARD BEAUTY.—A bright rose-coloured flower of the Nicholli group, belonging to *L. scoparium*. Award of Merit, July 6th.

LILAC PRESIDENT FALLIERES.—A double-flowered variety raised by M. Lemoine, of Nancy. The flowers are large and of a soft lilac tint. Award of Merit, May 23rd.

LILAC REAUMUR.—Another of M. Lemoine's raising, but with single dark carmine flowers. Award of Merit, May 23rd.

LOMATIA FERRUGINEA.—A very ornamental evergreen shrub belonging to the Protea family. It forms a dense bush, which, under favourable conditions, will attain a height of 10 feet to 12 feet. The much divided leaves give it quite a Fern-like character, while the flowers, borne in the summer, are rosy-red and white, suggesting those of some of the Grevillias. It is a native of Chili, and, like many shrubs from that region, is seen at its best only in the milder parts of the British Isles. A liberal amount of atmospheric moisture suits it best. Also known as *L. piunatifolia*. Award of Merit, August 1st.

OLEARIA SEMI-DENTATA.—A very striking member of the New Zealand Daisy-trees. Like the preceding, it needs a mild locality. The leaves are hoary on the undersides, and the large flower-heads are of a pale-mauve tint, with a deeper centre. Award of Merit, June 20th.

PYRUS MALUS ALDENHAMENSIS.—A very showy *Pyrus* that may have been obtained from *P. floribunda* and *P. Niedzwetzkyana*. It is very free-flowering, and the blossoms are of a rich pink colour. Award of Merit, May 16th.

PYRUS VILMORINI.—A very distinct and attractive member of the *Sorbus* group. It forms a shrub or small tree, remarkable for its small, handsomely-divided leaves and clusters of pure-white blossoms. The fruits, too, are very distinct, in colour being of a pale rosy-red tint. It is a native of Western China, and has proved to be quite hardy. Award of Merit, September 26th.

RHODODENDRON BAGSHOT RUBY.—A very showy variety that bears in great profusion compact trusses of rich ruby-red flowers. Award of Merit, May 23rd.

RHODODENDRON DONALD WATERER.—The flowers of this are pinkish-white, with a deeper coloured border. The inside of the flower is dotted on the upper part with brownish yellow. Award of Merit, June 6th.

RHODODENDRON DIPHOLE PINK.—A variety with clear rose-pink blossoms, with yellowish dots on the upper petal. Award of Merit, June 6th.

RHODODENDRON DUCHESS OF TECK.—This produces large clusters of pale rose-coloured flowers edged with a deeper tint. Award of Merit, June 6th.

RIBES CRUENTUM.—One of the Californian Gooseberries with Fuchsia-like blossoms, the calyx crimson and the petals white. It forms a deciduous spiny bush 3 feet to 6 feet high. Award of Merit, May 2nd.

ROSA MOYESI.—A beautiful species from Western China that forms a large bush, whose flowers are of a distinct shade of rich red, while the scarlet, bottle-shaped fruits also form a striking feature. It received an Award of Merit some time ago. First-class Certificate, June 20th.

SPHERALCEA CANESCENS.—A sub-shrub belonging to the Mallow family, with hoary

leaves, and rich orange coloured flowers. Suitable only for the milder districts. Award of Merit, June 20th.

TRICUSPIDARIA LANCEOLATA.—One of the most striking of evergreen shrubs. It was first introduced from Chili in 1848, and is seen at its best in mild districts with plenty of atmospheric moisture. The rich-crimson, urn-shaped blossoms hang suspended by long stalks. Known also as *Tricuspidaria dependens*, *Tricuspidaria hexapetala*, and *Crinodendron Hookerianum*. First-class Certificate, June 20th.

VIBURNUM DASYANTHUM.—A deciduous species from China that forms a bold-growing bush. The most notable feature is the autumnal crop of bright-red berries. Award of Merit, October 10th.

W. T.

CORONILLAS.

CORONILLA GLAUCA is so well known and so commonly grown that there is no need to say anything about it, but there are two others closely allied that are worth growing and, generally speaking, very little known.

C. VALENTINA is a particularly useful and cheerful winter-flowering shrub on the Riviera, as it blooms all through the winter, beginning in early November and reaching its fullest beauty in the month of February. It is more slender in growth than *C. glauca* and makes long shoots that bend down with the weight of the mass of flowers. While perfectly hardy on a dry bank, whether in sun or shade, it is a trifle less hardy than *C. glauca*. It seeds itself so freely that it is well to pull up the older bushes that have grown lanky, to make room for the young ones. *C. glauca*, on the other hand, does not naturalise itself in the same way. In the end of February, when *C. Valentina* is covered with seed-pods, it is necessary, if you wish to keep the older bushes in health, to cut it back freely and spare it the exhaustion of excessive seed-bearing.

C. CORONATA begins to flower in March and is the most powerfully scented of the three. This is in some ways the finest and most vigorous of all. Unlike *C. glauca*, whose habit is rather close and needs staking when in full flower, *C. coronata* makes a bold and vigorous growth, quite stiff and sturdy in stem, and with rather solid deep green leaves. It hybridises freely with *C. Valentina* when they happen to coincide in their flowering period, while I have never noticed traces of variation in *C. glauca* seedlings. *C. coronata* makes by far the finest bush of the three; I have seen it 7 feet or more in height, but then it is apt to get overweighted with its flowers after heavy spring storms of rain. On a warm April day or towards the end of March the whole air is filled with the powerful scent of this plant, which delights in the semi-shelter of an open wood in this climate, but it is much hardier and more robust than *C. glauca* and should survive ordinary seasons in most English gardens, where, of course, it will not bloom till May or June, being the last of the trio in time of flowering.

To sum up the comparative merits of the three, I should say that *C. Valentina* is the best pot plant, as it flowers so freely all through the winter; and as it stands pruning so well, its rather lanky growth is no objection. Its bright green leaves and stems are always attractive, but it has little or no scent unless it has a touch of *C. coronata* in its parentage. *C. glauca* is the least charming of the set. *C. coronata* is much the finest shrub for outdoors or for a big pot. It would not be satisfactory in a stunted and starved condition. Its bold habit, however, and powerful perfume make it very desirable for corridors or big

cold houses, and I feel sure that in the South of England it is a better shrub for outdoor gardening than the better-known *C. glauca*.—E. H. WOODALL in *The Garden*.

PRESERVING TIMBER BY CHARRING.

THERE can be no doubt as to the beneficial effect of charring Oak posts before placing them in the ground. In renewing, on the Holwood Estate in Kent, an Oak boundary fence that had been erected for seventy-three years, it was found that the majority of the old posts, or rather that portion of each that had been charred, was perfectly sound. Probably the open, porous soil, as well as the charring, had something to do with the condition of the posts. Be that as it may, the fence had cost little in the way of repairs for just on three-quarters of a century. To the last the charred part of the posts, which extended to about 1 foot above and 3 feet beneath the ground, was perfectly sound, the remaining portions being so decayed that they would not carry the horizontal bars on which the upright pales were nailed. The charring is readily and cheaply carried out as the fence is being erected by lighting a fire of wood and placing that portion of each post which is to be treated over the flame. This is easily carried out by supporting the ends of each post on a stone or block of wood at about 2 feet from the ground, the fire being made of old posts and rails. The wood should not be merely surface-scorched, but thoroughly burnt or charred to fully half an inch in depth. This forces the tannin and other products inwards and forms an outer crust or covering to the timber, thus effectually sealing up the inner layers of wood and preventing the ingress of moisture as well as the attacks of insects and fungus. Where charring is most beneficial is a foot above and entirely below ground-level, which in most cases will be from 3 feet to 4 feet in length of each post, this being the part that is most readily affected by atmospheric and other changes. The lifetime of the timber may be still further increased by dipping the burnt end of each post in a barrel of tar. As both the charring and tarring can be expeditiously and cheaply carried out as the erection of the fence proceeds, there is no reason why this simple method of prolonging the life of Oak fencing should not be generally resorted to. The cost of charring and tarring works out at 2s. 6d. per 100 posts. A. D. W.

The trailing *Arbutus* (*Epigaea repens*), although at home a common native plant in cool woods throughout the north and north-eastern States, usually does not do well when attempts are made to take it from its natural surroundings and place it under garden conditions. Unlike most ericaceous plants, it grows in areas where lime is present in the soil, for the writer has seen it thriving over large areas of limestone regions. It is also common in regions where there is no lime in the soil. Usually it is found at its best in sandy loam, on a gravelly, well-drained subsoil, under partial shade, with its roots penetrating a cover of leaf-soil or humus. The only thing to do is to try and imitate these conditions. In removing it from its native haunts dense tufts of low-growing and apparently young plants should be selected. These should be lifted intact and to such a depth that the roots are not in the least disturbed and placed in conditions in the home grounds or garden exactly similar to those from which they were taken. To place the plants in ordinary herbaceous borders and cultivate them in the same way as *Columbines*, *Campanulas*, *Iris*es, etc., certainly means failure. If there is

not a cool "woody" corner on the grounds, select some sloping corner as near as possible to these conditions, well drained, cool, and partially shaded. They must not be choked out with Grass or coarse weeds. In dry weather water the plants occasionally. In winter give a little mulching of leaves.—*American Florist*.

THE RED-DROP BARBERRY

(*BERBERIS RUBROSTILLA*).

THIS graceful and very beautiful form received a first-class certificate from the Royal Horticultural Society on November 7th last, and probably no member of the genus has better deserved that honour. Of more or less erect carriage and freely branched in its upper parts, it is of exceptional beauty late in the year when full of brilliant coral-red fruits, which dangle on short foot-stalks from the undersides of the branches. Overcrowding of the fruit clusters is not present; instead, there is an easy distribution of them throughout the greater portion of the arching branches, which renders the plant of considerable decorative value. The spiny character of the new comer, which is, presumably, of hybrid origin, should guard the berries from the attacks of birds. It is summer-leaving, and was sent up from

30 feet high; here it is about half that height with a considerable spread. During June and July pendent inflorescences up to 9 inches long of white flowers, which are followed by curious hairy fruits, are produced. It requires a sunny position, and thrives in loamy soil, forming a good shrub for gardens where uncommon subjects are desired.—D.

Cotoneaster horizontalis.—The berries of *Cotoneaster horizontalis* are still bright. In few years does this *Cotoneaster* fail to set its fruits profusely. At present they are as brilliant as those of the Holly, and give a bright little bit of colouring highly acceptable at this time of the year.—S. ARNOTT.

PLANTS AND FLOWERS.

INDOOR PLANTS.

STOVE AND GREENHOUSE PLANTS CERTIFICATED IN 1916.

DURING the year no first-class certificates were given to stove and greenhouse plants, but the following, excluding *Chrysanthemums*, received Awards of Merit:—

AURICULA EDITH.—A distinct variety, whose flowers are of a rich lilac-purple colour with a yellow centre. May 16th.

BEGONIA MRS. C. F. LANGDON.—A bril-

EUCHARIS LAWRENCEE.—The flowers of this are large and bold, while the habit of the plant is robust. It is said to be the result of a cross between *E. Richardiana* and *E. Burfordensis*. January 25th.

KENNEDYA ROSEA.—An old but by no means well-known member of this genus of Australian climbing plants. In this species the flowers are white, or nearly so, with a rosy shade. February 22nd.

LACHENALIA ROSEMARY.—This is a striking garden variety of an orange-red colour, marked with green and crimson. February 8th.

NERINE ROTHERSIDE.—A welcome addition to this desirable class of autumn-flowering bulbous plants. The flowers are of a clear, rich-salmon colour, and the crinkled segments are sprinkled with glittering coronations. October 10th.

PELARGONIUM GENERAL JOFFRE.—Said to be a sport from the well-known King of Denmark. The semi-double salmon-coloured flowers are shaded with orange-scarlet. October 10th.

PRIMULA MALACOIDES PRINCE ALBERT.—A particularly bold, richly-coloured variety of this universally-grown *Primula*. February 22nd.

PRIMULA ZULEIKA DOBSON.—Said to be the result of crossing *Primula viscosa* with a variety of show *Auricula*. The new-comer has very large bluish-purple coloured flowers, with a conspicuous white eye. April 11th.

SPIRÆA PRINCESS MARY.—A very fine type of pink-flowered *Spiræa* of the Queen Alexandra class. May 10th.

STREPTOCARPUS ROSE QUEEN.—The large rose-coloured blossoms are freely borne. It represents a superior strain. July 4th.

STREPTOCARPUS SOUTHGATE WHITE.—Equally beautiful as the preceding, but with white flowers. July 4th. W. T.

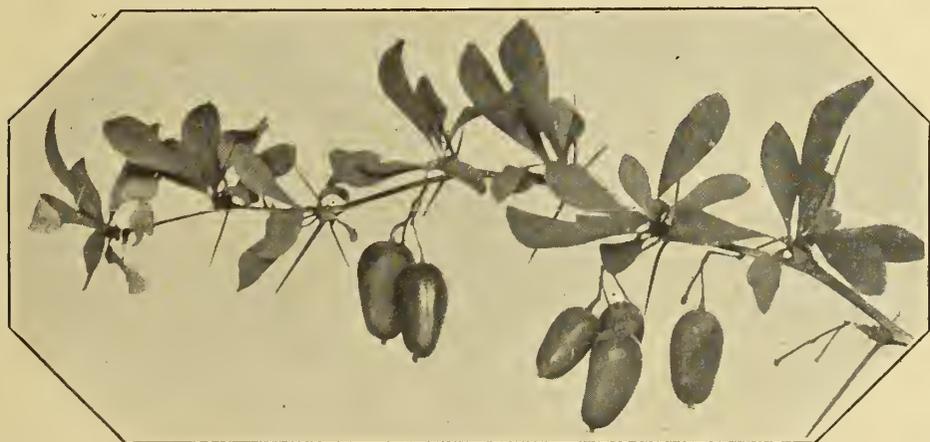

NOTES AND REPLIES.

Begonias unhealthy.—Will you please let me know what is wrong with these leaves of *Begonia Gloire de Lorraine*? My plants are the same each year.—SALOPIAN.

[The trouble with your *Begonias* is, undoubtedly, caused by the plants being grown in too close and moisture-laden an atmosphere. Owing to this the leaves are extremely succulent and apt to decay at the edges. In order to retain the foliage in good condition this *Begonia* needs a light buoyant atmosphere, free from draughts, and a temperature at this season of 55 degs. to 65 degs. At the same time, the structure in which the plants are must not be too dry, otherwise the *Begonia* mite and thrips will be liable to put in an appearance. These may be kept under by vaporising with nicotine. The appearance of the leaves sent would suggest that the plants may have had rather an excess of stimulants, but, of course, we cannot say definitely. A few words as to the treatment the plants have received would have been of great assistance to us towards determining the cause of the trouble.]

Habrothamnus, treatment of.—Can you tell me how to treat some plants of *Habrothamnus* in order to induce them to flower? I raised them from seed, and they are now three years or four years old, fine-looking plants, some 3 feet or 4 feet high.—W. M. CROWFOOT.

[The *Habrothamnuses* are naturally of a loose, rambling habit of growth, and the most satisfactory way of inducing them to flower will be to train them up the wall or supporting pillars of the greenhouse. It is very essential that they get a reasonable amount of light and sunshine. If they can be planted out in a small border, so much the better. Provided it is necessary to keep them in pots, they should in the spring have a fairly liberal shift, using

Berried shoot of Berberis rubrostilla.

the Society's Wisley Gardens, where it originated.

—This Barberry was brought to public notice on November 7th of the present year, when fruiting specimens were exhibited at the fortnightly meeting of the Royal Horticultural Society, the Floral Committee awarding the plant a first-class certificate. It originated in the gardens of the Royal Horticultural Society at Wisley as a chance hybrid from *Berberis Wilsonæ* and, it is thought, *B. concinna*. In habit it forms a shapely, well-branched bush, the branches thickly beset with slender spines nearly an inch long. The yellow flowers in spring are followed by small clusters of rich red fruits, about four being borne together. Individual fruits are about half an inch long and very similar in shape to those of *B. concinna*. When exhibited early in November they were at their best.—D.

NOTES AND REPLIES.

Pterostyrax hispidum.—The genus *Pterostyrax* is allied to *Halesia*, and the species are sometimes included with the *Halesias*, though the two families are abundantly distinct. The plant under notice, a large-growing deciduous shrub or small tree, native of China and Japan, has been in cultivation here since 1875. In its native country it sometimes grows upwards of

liant deep orange coloured flower. It belongs to the Rose type of double varieties. July 4th.

BEGONIA NORBURY WHITE.—Said to be a sport from Her Majesty. Flowers white, tinged with pink towards the edge. January 11th.

CARNATION GRIZEL.—One of the Perpetual-flowering class, with bright purple flowers. March 28th.

CARNATION J. G. FORTESCUE.—Said to be a sport from Horace Hutchinson, a small Malmaison type of flower, white, heavily flaked red. May 16th.

CARNATION LORD KITCHENER.—A Perpetual-flowering variety of a bright salmon-pink colour, with a pleasing fragrance. May 2nd.

CARNATION ROSE SENSATION.—A sport from the Perpetual-flowering variety *Sensation*. The flowers are of good shape, the calyx good, and the colour a kind of rosy-cerise. November 21st.

CINERARIA MATADOR.—This variety, which has been grown for some time, has massive heads of flowers of a distinct cinnabar-red colour, the undersides of the florets of a pale tint. February 22nd.

COLUMNEA GLORIOSA DISCOLOR.—A very striking Gesneraceous plant of pendent growth, suited for a hanging-basket. The large, curiously-hooded flowers are scarlet and yellow. January 20th.

a mixture of loam, peat, or leaf-mould, and sand, the loam being double the amount of the peat or leaf-mould. They will then grow away freely, when they may be trained to any support, and will, no doubt, flower in due course. If they are kept altogether in pots and just secured to a stake, instead of training them up a pillar, they may in the summer be plunged in a sunny spot out-of-doors, where the growths will be well ripened, and plenty of flowers the probable result. Care should be taken that they are not allowed to suffer from want of water when outside. As the pots get full of roots an occasional stimulant in the shape of liquid-manure or one of the plant foods now available will be very beneficial. Of course, the plants must be removed under cover before autumn frosts make their appearance.]

Cuttings in heated pits.—When cuttings are stored over winter in pits heated by hot-water pipes it is obvious that the soil will dry up much more quickly than would be the case in cold-frames. It is, therefore, necessary from time to time to inspect such cuttings in order that over-dryness may be guarded against. Naturally, during the dull months there will not be very much moisture required; but it is as well to make an inspection at stated intervals, at the same time removing all decayed leaves.

Bouvardias.—Comparatively few Bouvardias appear to be grown compared with the numbers met with years ago. In a garden I visited the other day a fair number of these useful winter-flowering plants were in bloom. Maiden's Blush (blush-rose), Hogarth (bright scarlet), and the white Alfred Neuner were all good.—S. M. S.

ROSES.

NOTES AND REPLIES.

Rambler Roses.—I should be glad if you would give me the names of half-a-dozen Rambler or similar Roses suitable for covering the front of a terrace. The position is full south and exposed to the westerly gales. Dorothy Perkins does well in this position, but I want other colours. I prefer Roses flowering over a long period, and, if possible, fragrant.—G. H. S. R.

[A few Roses of the Dorothy Perkins type are Lady Godiva (soft flesh-pink), Rene Andre (saffron-yellow, suffused with orange-red), Sweetheart (light pink shading off to white), Alberic Barbier (creamy-white), Excelsa (crimson-scarlet), and White Dorothy Perkins. These, like Dorothy Perkins, are almost evergreen, and the second, third, and fourth are fragrant. They also remain in bloom for a long time. Of the multiflora section, of which Crimson Rambler may be taken as a type, there are Mrs. F. W. Flight (bright pink, one of the best), Euphrosyne (pale pink, white centre), Blush Rambler, Flower of Fairfield (similar to Crimson Rambler, perpetual bloomer), White Tausendschon, and Tausendschon (large pink flowers). If you wish for a variety with bright crimson flowers substitute Philadelphia Rambler for the last-named. Paul's Scarlet Climber would be worthy of a trial. We also append a list of six varieties of climbing Tea Roses, which may, perhaps, be useful. These do not grow so tall nor cover so large an area as the preceding. Caroline Test-out (bright pink), Gruss an Teplitz (crimson), J. B. Clark (scarlet), Belle Lyonnaise (creamy-white), Billiard et Barre (orange-yellow), and Tea Rambler (coppery-pink.)

Rose Jessie.—This dwarf Polyantha has been very fine this year in the south-west of Scotland. It is one of those which has not been much affected with mildew in a season in which this pest has been unusually prevalent, and when in many gardens the scarcity of labour made it almost impossible to do anything to check it.—S. A.

CHRYSANTHEMUMS.

CHRYSANTHEMUMS: NEW EARLY-FLOWERING VARIETIES.

Those who have grown the early-flowering Chrysanthemums have been disappointed because so few new sorts have been introduced in recent years. Not a great many years ago French and other raisers sent us quite a large number of very beautiful new sorts, and for several years English raisers, too, were very successful in the novelties they introduced. We appear to have been quite stationary in this respect for some three or four years at least. It is all the more gratifying, therefore, to find that new varieties from a quite original source have been seen in public for the first time this season, and these novelties are of the very best. Mr. A. W. Thorpe, of Lichfield, has taken up the cultivation of early-flowering Chrysanthemums professionally, and if we may take the four new sorts which he has submitted to the Floral Committees of the National Chrysanthemum Society and the Royal Horticultural Society as an earnest of his work in raising new sorts we may, with confidence, anticipate great things from this source. First-class certificates, Awards of Merit, and commendations have been gained in London for each of his novelties, and he has also been successful across the border when he has submitted flowers to the leading Horticultural Societies. In the early days he, like many other growers, grew his plants naturally, *i.e.*, he allowed his plants to grow on to the terminal buds without any stopping or pinching of the growths, and the terminal buds were not disbudded. Very beautiful results are usually obtained in this way. In later years, however, a demand has risen up among market growers and others for Chrysanthemums that will produce a good crop of disbudded blooms under fairly easy culture. It is astonishing how kindly some plants take to this disbudded method of culture. The varieties that Mr. Thorpe brought to London and placed before the respective Floral Committees of the National Chrysanthemum Society and Royal Horticultural Society appeared to succeed very well under both systems of culture—disbudded and undisbudded. The following four varieties have gained several distinctions:—

HARRY THORPE.—A handsome flower of a bronzy-yellow colour having long florets of medium breadth, making a splendid flower some 5 inches in diameter when disbudded. It is the result of a cross between Hector and Golden Glow, Hector being the seed parent. Raised in 1913. Commended National Chrysanthemum Society and Award of Merit Royal Horticultural Society. This plant is also good when naturally grown.

DICK BARNES.—This is a splendid acquisition to the rosy-crimson—some say rich crimson—sorts. It is a seedling from Dolores and an unnamed variety, and the seed parent was Dolores. Raised in 1914. The plant is about 3 feet high. It is good disbudded or undisbudded. First-class certificate National Chrysanthemum Society and commended also by the National Chrysanthemum Society as a market variety. Award of Merit Royal Horticultural Society September 26th last.

LICHFIELD PINK.—In this the colour is a soft mauve-pink, and the form, of a slightly drooping character, exquisite. This is a seedling from Hector and Dolores, Hector being the seed parent. Raised in 1914. Useful for cutting and home decoration, and splendid for market. First-class certificate National Chrysanthemum Society and Award of Merit Royal Horticultural

Society October 10th last. The National Chrysanthemum Society's award was made eight days earlier.

NELLIE THORPE.—Although not so good as the others, this is a very dainty sort of a bronzy colour, and also of pleasing form. It is a seedling from Golden Glow and Dolores, the latter being the pollen parent. Raised in 1914. E. G.

NOTES AND REPLIES.

Chrysanthemum La Triomphante.—This old variety, and its sports White Triomphante and Yellow Triomphante, are behaving rather curiously this season. On the type, in addition to the pink blooms, there are pure white flowers, and on the white sport there are white, pink, and pink-and-white blooms. The yellow sport, too, is throwing white flowers. I still grow a goodly number of La Triomphante, and, if old and rather addicted to mildew, I would not care to discard it in favour of many of the more modern Chrysanthemums.—W. McG.

Chrysanthemum Lady Stanley.—This was one of three varieties which received an Award of Merit from the Royal Horticultural Society on November 21st last. It is of the decorative set, that ranging itself, as it were, between the exhibition sorts and hardier border varieties, finds such favour with the market-man and the florist. To be favoured by the market-man the flower must be firm and crisp of petal, and, therefore, travelling well, and of good colour. If combining all these attributes it will soon take front rank. That named above is well endowed in some respects—colour, a refined silvery-pink; and that petal crispness which denotes lasting properties. Under artificial light it is excellent. It was staged by Messrs. Wells, Limited.—E. J.

Single Chrysanthemum Doris Stevenson.—This has been very good this season, and has been valuable from the middle of November. It is a very attractive variety, suitable either for growing naturally or disbudded. The florets are broad and flat, and the colour is of the deepest crimson, which sets off the golden disc to advantage.—SCOT.

Chrysanthemums after flowering.—There is nothing gained by allowing Chrysanthemums to occupy room in a greenhouse after they have done flowering. It is an advantage to lightly stir the soil, and in the case of varieties backward in producing cuttings to add a little fresh soil, and if need be give additional warmth. Generally speaking, however, the cooler the conditions which prevail the better and stronger are the cuttings which are produced.—LEAHURST.

Chrysanthemum Niveus.—Discussing late Chrysanthemums with a market-grower in the south-west of Scotland the other day, he assured me that Niveus was still the most useful variety for sale. He grows it in great numbers, and finds a ready sale for the blooms. The flowers are of a really good white, the shape also good, and the plants bloom freely. The grower referred to finds that large blooms do not now pay, as was at one time the case.—S. A.

Single Chrysanthemum Countess of Egmont.—In this we have one of the brightest and most effective of the single Chrysanthemums. It is of good size, with several rows of petals, the colour orange with a tinge of terra-cotta. It makes a good plant, and is excellent either grown naturally or disbudded. It was one of the best in a nice collection I saw the other day.—SCOTSMAN.

Chrysanthemum Mensa.—This still remains one of the best white singles. If disbudded, it can be grown to a great size; but I think flowers from disbudded sprays are not so effective as those more naturally grown. The yellow variety is, decidedly, not so good as the type, the colour being a poor yellow.—SCOT.

Single Chrysanthemum Peter Pan.—This small-flowered variety is especially adapted for cutting in sprays. When well grown it will give sprays of flowers almost, if not quite, 9 inches long, composed of from fifteen to twenty individual blooms, starry in form and of a charming fawn colour.—SCOTSMAN.

ROCK, ALPINE, BOG, FERN, AND WATER GARDENS.**WATER HOLES NEAR HOUSE.**

Of recent years it has been the custom of people who aspire to be "landscape architects" to introduce into gardens a number of silly little incisions for holding water. These are very often not fenced in any way and are usually not big enough for a frog to swim in. In a garden in Surrey there is a little canal 8 inches wide running through the flower garden. It is difficult to suppose that any gardener would make such a puny thing for the growth of delightful water plants. If we want water

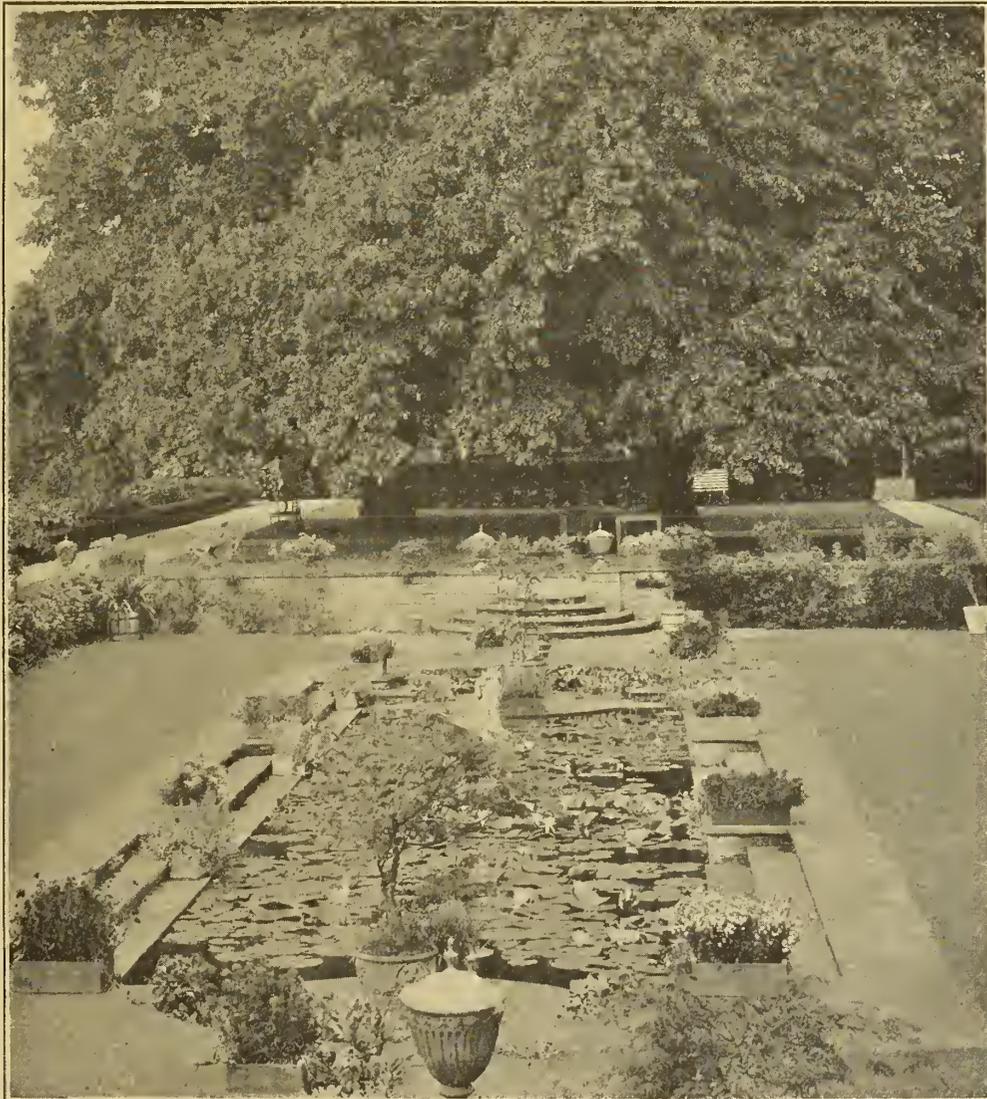

evidently resent the weather conditions and miss the natural covering of snow at home. One may again repeat the useful cultural hint which has often proved so effective, and this is that they should be covered with glass from about the beginning of October until they flower. A sheet of glass supported on a wire frame supplies all they want during the winter months. The great necessity is dryness overhead.—S. ARNOTT.

GARDEN PESTS AND FRIENDS.**NOTES AND REPLIES.**

The Cabbage caterpillar.—On taking over a new garden at the end of September, I found all Cabbages, Broccoli, etc., almost entirely

hand-picked, doing this directly caterpillars are found on the plants. It is a tiresome business, but a boy or girl can pick off and dispatch a great number in the course of a few days. This is a better method than trying to get rid of them by applying insecticides, for reasons which are obvious.]

The Raspberry-bud caterpillar.—I was sorry to see this was directing its attention to the Loganberry (p. 528). We shall have it attacking the homely Blackberry next if it has not already started. The information respecting the bright red larvæ of the *Lampronia* is not altogether correct in some cases. It is said, for instance, the larvæ are found feeding on the tips, work-

Garden basin at Buckhurst.

it is well to put it at a distance from the house, if only to guard against mosquitoes and things of the sort, not to name the danger that water in such a place is to children and people of unsteady gait. There is no room to work in such little puddles. The one we show is a little bolder than most of them, but still, we think it not nearly so good as water in its right place, where it can be done. The "stews" made use of in old gardens were quite a different and better thing, also a stream led through a garden as at Littlecote and other places was charming and of some use and meaning.

The Soldanellas.—Many disappointments are experienced by growers of the *Soldanellas* from their shyness of flowering. They

devoured by a plague of caterpillars of the Cabbage white butterfly. They have somewhat recovered, but I am anxious to avoid a return, particularly as I am told that the plague has occurred three years in succession. I have some well sweetened gas-lime. When the crop is cleared off would it kill the chrysalises if I were to have this dug in? What quantity should be applied?—CAMBRIDGE.

[The gas lime will certainly do good, as it will kill any pupæ which may be present in the soil, as well as other species of insects. The gas lime should be reduced to a fine condition and applied at the rate of a breakfast cupful to a square yard. Do this at once and incorporate it as thoroughly as possible with the soil in the course of digging it. The attack, both present and future, can be greatly reduced by

ing their way down the shoot, whereas they are generally found working up from the base. It is one of the enemies to plants extremely difficult to deal with, and although one can reduce the numbers by clearing away everything at the base after the fall of the leaf, including an inch of soil, there is no guarantee it will not be more or less in evidence another season. It would almost seem that the only effectual remedy would be to spray occasionally very early in the season. Doubtless in the promised information, we shall get, as well as the life-history of the pest, the best means to adopt to check it. The larvæ of a beetle are also very troublesome in some districts, and this would also seem to be found largely on Blackberries.—E. B. S., *Hardwick*.

GARDEN FOOD.

SOME EFFECTS OF GARDEN FOOD.

A READER has called our attention to some unpleasant effects of adopting a diet of the above, and asks our opinion.

Without doubt such effects may occur, but mainly they are not the fault of the food. In our great cities, where the question mainly arises, there is harm done by bad choice of kinds and their being obtained in a coarse or wilted state. As to kinds, our markets are well supplied with coarse Cabbages, ill-flavoured Broccoli, Carrots big enough for a shire horse, and overgrown Beans and Parsnips. These may, without doubt, be blamed for some of the discomfort named, but there are much more wholesome things to be had. Also these first enumerated kinds are not uncommonly sold in anything but a fresh state, and are afterwards ill-treated by the cook.

Considering the great amount of food obtained from our gardens, farms, and orchards, there are many such things absolutely free from any such unpleasant effect. In the gardens, for instance, Spinach, Artichokes, English Peas, French Beans, Celeriac, and the American Sweet Corn, which is quite wholesome, cooked Lettuce and Cucumber are free from objection.

Also the question of cookery comes in with much effect. For instance, there are the dried pulse, Haricots, Peas, and Lentils, we use in the winter. As served in England they are not always well cooked. In France they are much better prepared, more digestible and so appetising they seem to melt in the mouth. Even so cooked the pulse require to be taken with moderation. The same thing treated by two cooks may have entirely different effects—wholesome in one case, injurious in the other.

Nothing would help us so much in this way as the adoption of the Italian way of cooking these precious pulse and cereals. The value of these foods may best be considered in view of the longevity and strength possessed by men of the great nations which live entirely on these foods without discomfort—the Italians, Greeks, Turks, other Balkan peoples, and some Indian and African races, Zulus, and Kroomen. Anybody open to consider evidence can have proof from these nations that foods from the vegetable kingdom are perfectly beneficial and can be used free from all the drawbacks mentioned.

The countryman has a great gain in getting his garden food fresh, and even the small cottager with his garden has a supply at his hand of healthy food, in itself sustaining and obtained at a minimum of exertion with the best results. The quack who heralds it that all his goods are from plants says nothing of the fact that the most deadly poisons come from the same source. We who claim much good from garden food must not copy the quack and must not try to conceal the fact that some of the food classed as vegetable is far from wholesome.

The way the Paris market is supplied with tender vegetables as compared with ours is instructive. The cook is the master of the market in Paris, and would at once return much of the vegetable and fruit that London folk have to put up with.

Green Top Beetroot.—What a conservative lot we gardeners are, to be sure! Nine out of ten of us sow year after year the purple-topped variety, because we think that unless the top is of this colour the roots cannot be Beetroot. Anyone who has tried Cheltenham Green Top Beetroot

will never grow the old-fashioned purple-leaved varieties, which more often than not are coarse and stringy. Cheltenham Green Top is a superb Beetroot, as soft and melting as a Willam's Pear, and every bit as sweet.—*Garden.*

WHAT TO DO WITH GREEN TOMATOES.

ALL growers of Tomatoes are faced at the end of the season with a quantity of green Tomatoes which will not ripen and are frequently thrown away. They, however, make not only delicious pickles, but nice jams, sauces, and chutney.

TOMATO PRESERVE.—Take 3 lb. of large green Tomatoes and slice them into a preserving-pan. Add the same quantity of sugar, four Lemons sliced very thinly and the pips removed, and a large red Chili. Allow all to stand until the syrup begins to run, then place the whole over a clear, bright fire, and bring slowly to a boil. Simmer gently, removing all scum as it rises, and stir continually to prevent burning. When the jam looks clear and of a pretty green colour test some, and if it thickens it is done. Pour into small glass jars, and cover in the ordinary manner with parchment paper.

GREEN TOMATO GINGER.—Take 6 lb. of small green Tomatoes and the same quantity of sugar. Bruise a $\frac{1}{2}$ lb. of fresh root Ginger, and place in a pan with a quart of water. When boiling hot plunge in the Tomatoes and allow them to simmer for five minutes. They must not break on any account. If any show signs of this take them up at once. When all have simmered for five minutes remove them from the pan and allow to drain. Add $\frac{1}{2}$ lb. of the sugar to the same water and boil up and skim. Turn in the Tomatoes and allow to just boil. Remove from the fire and allow them to stand until quite cold. Drain off the syrup and return to the pan and add half the remaining sugar and once more boil up and skim carefully. Turn in the Tomatoes and stand the whole aside until the next day, when once more boil up. Take out the Tomatoes with a skimmer and drain on a sieve until the remaining sugar has been added, then after boiling and skimming replace the Tomatoes and boil until quite clear. Set the pan aside with a cloth over till the whole is cold, and then boil up again for five minutes. Repeat this a second time, then, if the syrup is thick enough, place the Tomatoes in jars and pour the syrup over. If, however, the syrup is thin, remove the fruit and boil for a few minutes or until thick enough. This preserve is better for keeping for a few months before eating as it improves in flavour the older it is.

GREEN TOMATO PRESERVE (another method).—Take 6 lb. of green Tomatoes and slice them into a pan with 4 lb. of sugar and 1 lb. of dry preserved ginger sliced, and the juice of three large Lemons. Place over a clear fire as soon as sufficient sugar has dissolved to prevent the pan burning. Simmer gently, and skim carefully for half an hour or till the preserve looks clear and stiffens when tested. Take care not to lose the pretty green colour by over-boiling. This is a delicious preserve, and not much trouble to make, and is much liked by children. Pour into small pots and cover in the ordinary way.

GREEN TOMATO CHUTNEY.—3 lb. of green Tomatoes, 3 lb. of Apples, 1 lb. of large raisins, 1 lb. of Shallots, a head of Garlic, 3 lb. of brown sugar, four large Chillies, one tablespoonful of salt, and a $\frac{1}{2}$ lb. of green ginger. Chop all the ingredients thoroughly, mix, and place in a jar large enough to hold them all. Pour over two quarts of brown vinegar. Cover the jar closely, and stand the whole in a slow oven for six hours. It should keep quite hot, but not boil. Set aside for a day, then stand in the oven till quite hot, and then remove to a cool place. Repeat this for six days. Stir the contents of the jar every time it is removed from the oven. Add a tablespoonful of mixed spice and a tablespoonful of common pepper, and turn the whole into a preserving-pan and simmer until the chutney is thick. This usually takes about an hour's simmering. Pour into large, wide-necked bottles and cork tightly. This chutney im-

proves with keeping, and will remain good for years.

SWEET GREEN TOMATO PICKLE.—Take small green Tomatoes and place in a jar with an equal quantity of peeled pickling Onions. Cover them with boiling white vinegar. Allow this to stand till the next day. Then drain off the vinegar and place it in a pan with a pound of granulated sugar for each pint of vinegar, a half a saltspoonful of cayenne pepper, and a teaspoonful of Mace and a few Cloves. Boil up, and skim if necessary. Add the Tomatoes and Onions, and simmer for ten minutes. Place the Onions and Tomatoes carefully and prettily in glass jars, and pour the vinegar over. Cork tightly, dip the tops of the bottles into melted bottling-wax, and store till required. This pickle keeps indefinitely.

GREEN TOMATO PICKLE.—Heat some white vinegar to boiling-point in a brass preserving-pan. Slice some Tomatoes across the fruit, and dip into the boiling vinegar to set the colour. Do this carefully or else the shape may be destroyed. Have ready some pickle-bottles, well cleaned and dried, and arrange the Tomato halves prettily and carefully in them. Fill up the spaces with sliced English Onions and a few small Chillies to give colour. Meanwhile, add a tablespoonful of sugar and salt to every quart of vinegar, 1 oz. of white pepper, a teaspoonful of allspice, a piece of ginger well bruised. Simmer these all well together until the vinegar is well flavoured. Pour as hot as possible over the contents of the bottles and stand aside. When cold, cover closely, and store for three months before eating. This is a very good plain pickle, and is usually much liked. Green Tomatoes may be added to any ordinary mixed pickle and do very well.

GREEN TOMATO SAUCE.—Take 6 lb. of large green Tomatoes and slice thinly into a pan with a pound of English Onions, also sliced, 2 lb. of brown sugar, two quarts of vinegar, a dessertspoonful of ground allspice, the same of Cloves, Cinnamon, Ginger, Mustard, and a pinch of Cayenne pepper. Boil all for twenty minutes. Then rub through a sieve and return the pulp to a pan and simmer for ten minutes longer. Bottle in wide-necked bottles and store till required. It is ready for immediate use. H. T. C.

NOTES AND REPLIES.

Apple Forge.—For some time past I have been using this well-known old Sussex Apple, both for eating and cooking, and for the latter purpose find it to be a fruit to which the addition of sugar is quite unnecessary. The rich sugary flavour which characterises well-grown, fully-ripened examples when eaten in a raw state is retained by the fruit when cooked, hence the adding of sugar, which is necessary to correct the acidity in many varieties of cooking Apples, is quite superfluous, a fact worth knowing now that this particular commodity is both scarce and dear. There are, of course, many varieties superior to Forge for eating, but when Apples are not plentiful medium-sized specimens make a very pretty dish for the table, and as regards flavour and juiciness, are not then to be despised. As is well known, the variety under notice derives its name, or is supposed to do so, from its having originated near to a forge in the old iron district of Sussex.—A. W.

A waste of Tomatoes in Jersey.—Tomatoes are grown here in the open fields, and this year's crop has been a splendid one, but, unfortunately, there have not been enough boats to take them away. One evening my father and I calculated that there were 300 tons of Tomatoes waiting on the quay all ready packed for shipping, but there were no boats to take them, and it was a heartrending sight to see cartloads of beautiful-looking Tomatoes being emptied into the sea. In the shops you could buy them at a halfpenny per pound, but you can get them for nothing if you take a basket to the growers.—*Garden.*

OUTDOOR PLANTS.

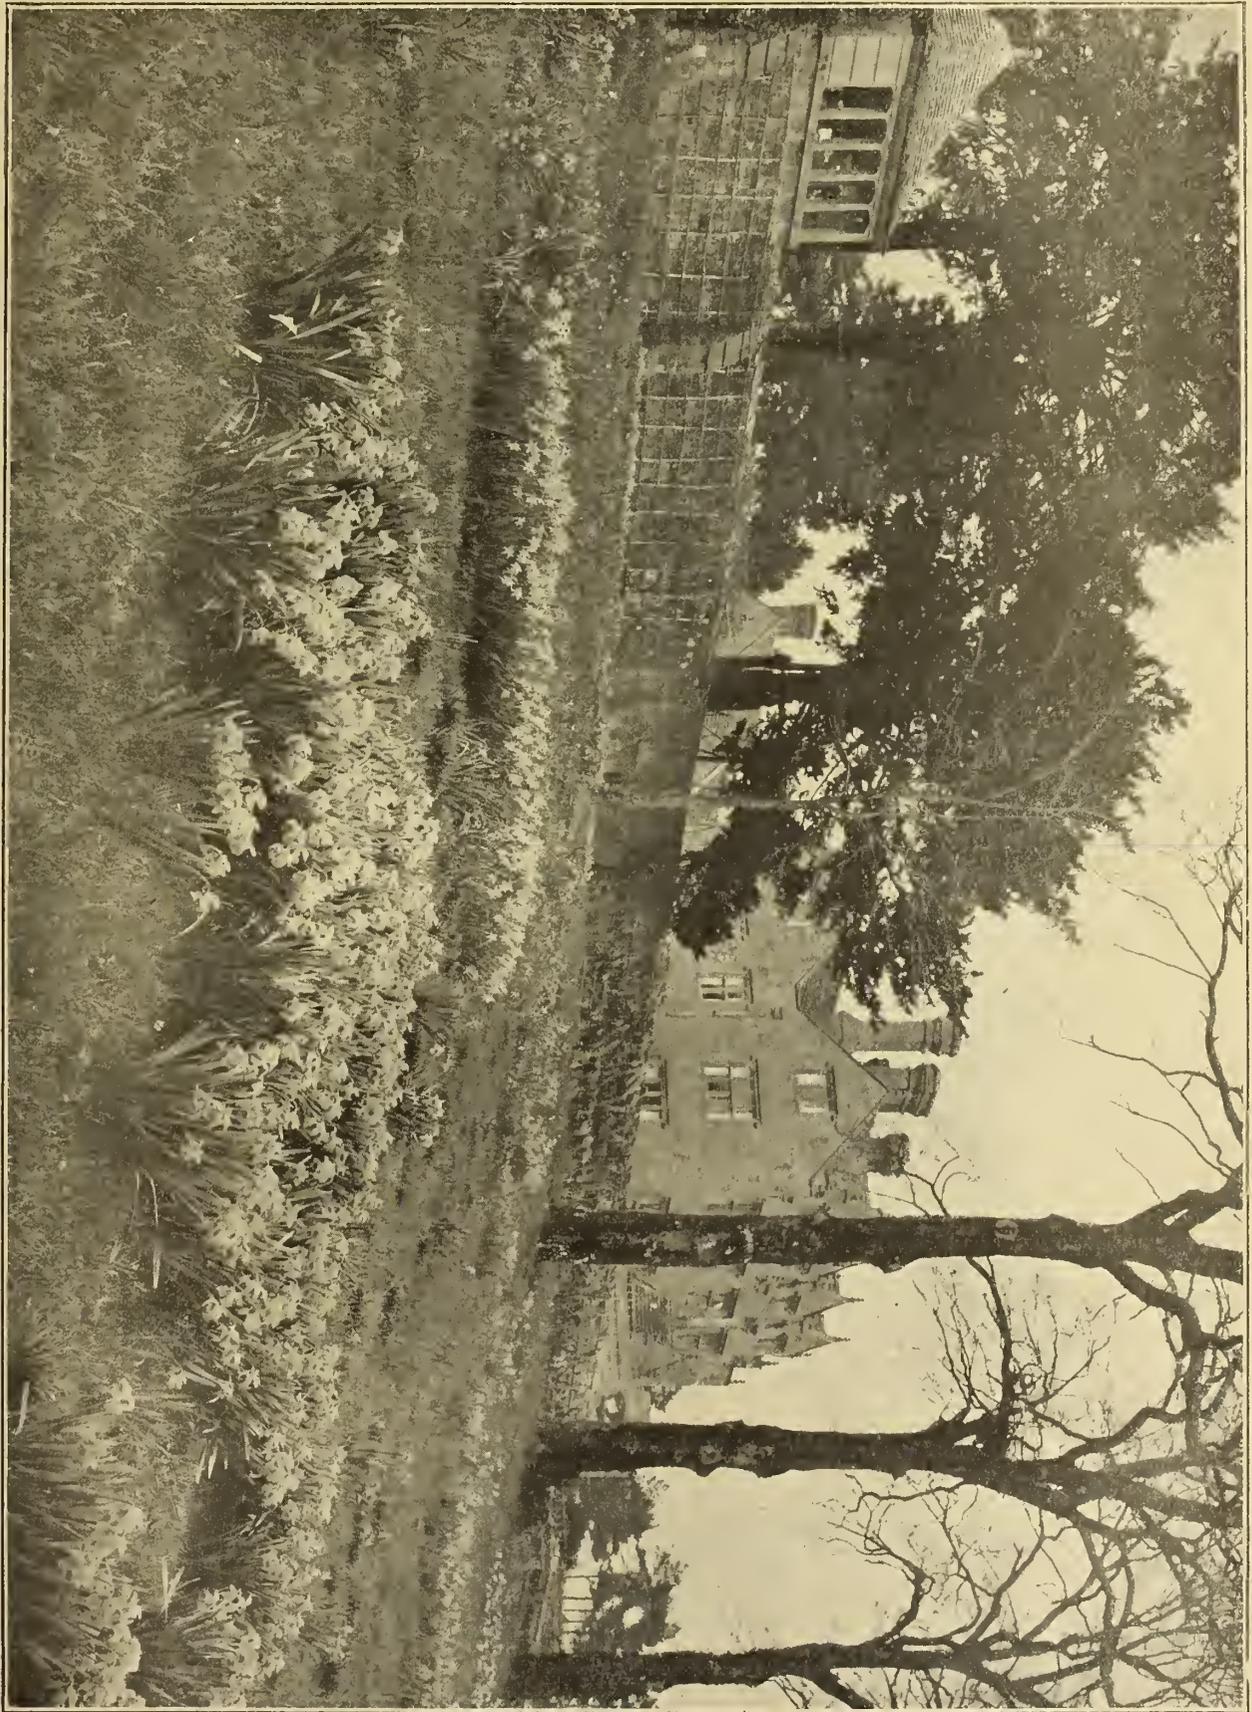

SPRING FLOWERS ON A LAWN.

If I had to do this again I think I would not plant Narcissi so freely, because there

way of scratching up the flower garden every year, simply putting into the Grass hardy things that cause no trouble, and leaving for the flower garden itself other things that want care, time, and patience to develop. On the lawn the best of the

snow for long months after the same plants are in bloom with us. Plants that show growth throughout the summer should be omitted from turf mown as this lawn is. The soil is cool loam on sandstone rock, and even better or different results may be

Spring flowers in the Grass (*Gravetye*).

are so many beautiful spring flowers that might be used. My general idea is that simple grouping is more effective, beautiful, and economical than scattering things all over the ground. The question of spring gardening in all country places is very easily settled by the abolition of the old

early spring flowers are grown, and do not mind in the least the mowing at hay-time, the leaves of Crocuses, Snowdrops, Blue Wood Anemones, and Snowflake by that time having gone or are dried up. The best selection is the early flowers that, on the mountains of Europe, are asleep in the

had on warm limestone soils, where Snow-drop, Crocus, and Winter Aconite would grow freely. W. R.

Ourisia coccinea from seed.—It is, I think, sometimes overlooked that this fine plant can be raised from seed, and with a minimum of

trouble. It is generally supposed to be a shy seed-bearer, but seed is by no means rare, and it germinates very readily. Any good firm which makes a speciality of hardy-flower seeds will supply those of *O. coccinea*. The recent discussion on the plant was interesting, for *O. coccinea* has acquired, rightly or wrongly, the reputation of being a very difficult subject.—W. METZ, *Balmac*.

HARDY PLANTS.

ONE of the most satisfactory features of modern gardening is the high position occupied by hardy plants. It was not always so. Many of your readers may be surprised to hear that there was a time when one would have to travel miles and visit a score or more gardens without seeing even a Japan Anemone or a Gentian. With the exception of some Crocuses, Snowdrops, old double Daffodils, and Wallflowers gardens generally were practically bare in early spring, and it was not until tender plants came into bloom that the outdoor garden was interesting. I am speaking of some fifty years ago, when the reign of the tender bedders began. I do know that before that time hardy plants were cherished, for I had the catalogue of a man named Cree, who had a hardy plant nursery at Addlestone, Surrey, and this list contained several hundred species and varieties, a large proportion of which were in pots in the same way that trade growers manage them nowadays. I remember one garden owned by a lady who must have been a hardy plant enthusiast, for, after her death, I found many things which I did not know at the time, and which I did not meet with for many years afterwards. The bedding craze, as it has been termed, was responsible for much evil in many places. Hardy plants were dug up to make room for long rows of tender plants. Some of these things became so uncommon that the younger generation of gardeners did not know them, and they had later on, when the change came, to be re-introduced. In a small garden here there was a white Everlasting Pea which must have been grown there many years, and which was the only plant I had ever seen in this locality.

It was moved and given a good position, and I managed to raise about a thousand plants, but the demand was so great that I could not meet it. Evidently this white variety was but little known at that time, and this is exactly what happened to a good many fine, hardy plants. They disappeared from gardens generally and found a refuge in out-of-the-way places.

There came a reaction and hardy plants once more came into their own. In spite of this progress much remains to be done. In the gardens of the wealthy, and where there is an experienced man in charge, hardy plants are grown in much variety, but it is otherwise in villa and small gardens generally. There is a drab monotony about them that is painful. One sees the Phloxes, Delphiniums, Michaelmas Daisies, etc., everywhere, but the dwarf-habited things, of which there are so many, are seldom seen. In how many villa gardens in this locality should I find a *Lithospermum*, *Platycodon*, or *Gaultheria*, for instance? Either from ignorance or indifference such things are rarely found in villa gardens, and one garden is the replica of another. There is nowadays no excuse for ignorance, there is the gardening literature, which is within the means of all and where notes are constantly appearing by experienced men.

The year 1916 is approaching its end, and I would urge those who may have been contented with the ordinary run of coarse-growing things to try some of the choicer hardy plants. Any of the following may be tried:—*Anemone Robinsonii*, A.

japonica Mont Rose, and A. Coupe d'Argent, *Astilbe* Silver Sheaf, *Lithospermum prostratum*, *Ranunculus acitofolius*, *Gentiana acaulis*, and *G. septemfida*, Rock Roses, *Epimediums*, *Cyclamen neapolitanum*, *Gillenia trifoliata*, and *Gaultheria Shallon*. These are a few of the numerous things that would impart variety.

J. CORNHILL.

AMONG THE HARDY FLOWERS

ERICA CARNEA.—This comes at a time when we have but few outdoor flowers, and appears utterly regardless of the weather. It may be a little later some years than others, but it never fails me in mid-winter, and though it may be shrouded in snow, pelted with sleet, or drenched with rain, it yet comes up smiling and cheery through it all. It does not need peat, a fact which should make it of more value to many of us amateurs, who often find a difficulty in securing this useful soil ingredient unless at considerable expense. It grows quite well with me in ordinary garden loam, not too heavy. There is now a considerable number of varieties of *Erica carnea*, but beginners may content themselves with *Erica carnea*, with its rosy-red flowers, and the white variety, with pearl-like flowers on the slender branches. With me *Erica carnea* does best in full sun, this being an advantage in winter, as it means that the plants can be put so as to face the south, and will, consequently, obtain almost every gleam of sunshine in the short days. I think, also, that it looks prettier when above the ground level. *Erica carnea* may be planted at almost any time, except in the dead of winter during frost or in the most torrid days of the year. I have always planted in spring, after flowering, or in earliest autumn, and in both cases have had no difficulty if a good soaking of water was given after planting.

PRIMULA SIEBOLDI IN THE OPEN.—This is one of the plants which die down to the crowns in winter. These crowns are exceedingly small, and invisible without careful examination, while they are easily injured when forking over the soil. I have found it necessary, unless when I have a few plants together in a group in a position absolutely familiar to me, to put a stout label to each plant. *Primula Sieboldi* is obtainable in several colours, some of them with names, and I have been successful in raising them from seeds sown in a small frame, in which the seeds were sown in spring in loam, leaf-soil, and sand.

MEADOW SAFFRONS (Colchicum).—My few clumps of these have got bigger, and where I had only one or two corms I now have several owing to their natural increase. I know gardens where there are very big clumps of some of the finest of these flowers, but it is pleasant to have them growing in one's own garden, even if there are only a few corms of one kind. The common *Colchicum autumnale* is to me one of the least useful. I admire *C. speciosum* and its white form as much as any, though the double varieties of *C. autumnale* are also worth attention.

HELIANTHUS MISS MELLISH.—A correspondent of mine in Scotland tells me that with him this sometimes flowers so late as to be spoiled by the frost before the blooms open. By giving it a warm, sunny place, I think *Helianthus* Miss Mellish should flower well in early autumn everywhere. The flowers of this ought to be cut before the disc or central florets expand. If this is done the blooms will open in water and last much longer.

AN AMATEUR OF HARDY FLOWERS.

Thalictrum corynellum.—This is a fine plant for the back of the hardy plant border.

The foliage is somewhat similar to that of the *Aquilegia*, and of graceful appearance. It flowers freely (especially in the southern counties) in June and July, some of the flower-sprays being 2 feet or more in length. Its height ranges from 4 feet to 6 feet, according to circumstances. The site should be well dug and freely enriched with rotted dung.—E. T. ELLIS, *Weetwood, Ecclesall, Sheffield*.

A WIGTOWNSHIRE GARDEN.

AMONG the notable things at Logan are the fine plants of *Cordylina australis*, established here for years and annually increasing in effect. There are many plants at Logan, and these flower and ripen seeds freely. Associated with a group of these is an uncommon thing in the open in Scottish gardens—*Dicksonia antarctica*.

Probably the finest plant of *Abutilon vitifolium* in the open in Scotland is that at Logan. It is of great size, and is most beautiful when in bloom with its hundreds of drooping lavender flowers. Logan is also one of the few Scottish gardens in which the Chatham Island Forget-me-not (*Myosotidium nobile*), is to be met with in the open in a really happy condition. It is given the shelter of a little straw in winter, but is otherwise unprotected, and annually shows above its handsome shining leaves its fine blue flowers. The white variety is also grown. Then the queenly Lily is also fully represented, and Logan is noted for this flower, especially for *L. auratum*, which is splendidly grown and shows its beauty in perfection in the congenial soil and climatic conditions.

The climate and surroundings would point to Logan being a favourable venue for the cultivation of the Himalayan *Rhododendrons*, and within a few years many of these have been planted. On the occasion of my visit they were looking very happy, indicating that they would prove in a few years equal to the other attractions of this garden.

A delightful scene is afforded by a Water Lily pond, so placed as to be in entire consonance with the spirit of the place—not an easy thing to do. When I visited this paradise the day was of the most brilliant kind, and the fine collection of the best *Nymphaeas* raised by M. Latour-Marliac and others was in full bloom.

There is a glorious bit of *Romneya Coulteri* 10 feet to 12 feet high. It is a true delight against and over a wall, and marvellously fine with its crinkled white blooms, each adorned by the golden stamens.

Phormiums abound in Wigtownshire, and Logan is no exception in possessing noble specimens of *P. tenax*. Then *Exogonum purga*, the Jalap-plant, a subject not too often met with, gives its handsome lilac-rose flowers in profusion, and *Eupatorium Weinmannianum* also flowers to perfection.

The attractions of this truly wonderful Scottish garden are not confined to uncommon subjects.—*The Garden*.

Late blooms.—The mildness of the season has resulted in the prolongation of the period of bloom in the case of many hardy plants. It is not claimed that the flowers in the annexed list are in first-class order; but they are sufficiently good for cutting, although, naturally, their duration is somewhat brief. The plants mentioned below were in bloom on December 4th, no notice being taken of the few shrubs which flower in the usual course of events at this season of the year:—*Potentillas* in variety, Japanese Anemones, Violets, Lothian and Ten-Week Stocks, Anthemises in variety, *Erysimums*, Pentstemons of the "Gem" varieties, *Alyssum*, *Schizostylis coccinea*, *Eupatorium ageratoides*, *Senecio grandiflora*, *Chrysanthemum*.

mum maximum, and Aster Drummondii. Hardy annuals include Godetia, Lavatera trimestris, and Saponaria calabrica. Fuchsias yet remain quite passable in the more sheltered places, while Chrysanthemum Mrs. Desgrange, Ceddie Mason, and Sylvia Slade, if a little weather-beaten, are yet usable. Roses, too, may yet be picked, these including Zephirin, Fellenberg, Fabvier, D. Perkins, Hiawatha, La France, and Captain Hayward. The Ten-Week Stocks referred to are the result of an experiment. The seeds were sown out-of-doors early in May—on the 8th of the month to be exact—and were afterwards pricked off into their flowering quarters. They made excellent progress, and the experiment will be repeated on a larger scale—and with these and similar half-hardy annuals—in 1917.—W. McG., *Balmœ, Kirkcudbright.*

"BEAR'S-BREECH" (ACANTHUS).

THESE rank high with the more stately-growing, hardy, fine-leaved plants, albeit they are too rarely seen in gardens. Ornamental in the highest degree, they are, by

thought of them for tubs and terrace gardening? I have never seen them thus, but, having grown them to a large size in pots for exhibition in the past, know something of their worth in the direction indicated. Well grown, a dozen plants of the best of them—*mollis*, *latifolius*, and *spinosa*—when established would, by reason of handsome proportions and high ornament, be a revelation. To this end, then, would I direct the attention of gardeners having terrace gardens to garnish, suggesting that youthful examples be first grown and established in pots as the best means of attaining success. With liberal cultivation and a year or two of patience this should be forthcoming, and, once established, may continue for years.

CULTURE.—Culturally the *Acanthuses* present few difficulties. Disliking heavy clay, and favouring warm soils, they grow and increase freely on those of a loamy nature, whether light, sandy, or stony, or of medium weight, in conjunction with a cool bottom. Rooting moderately deep, the soil should be well prepared, the more

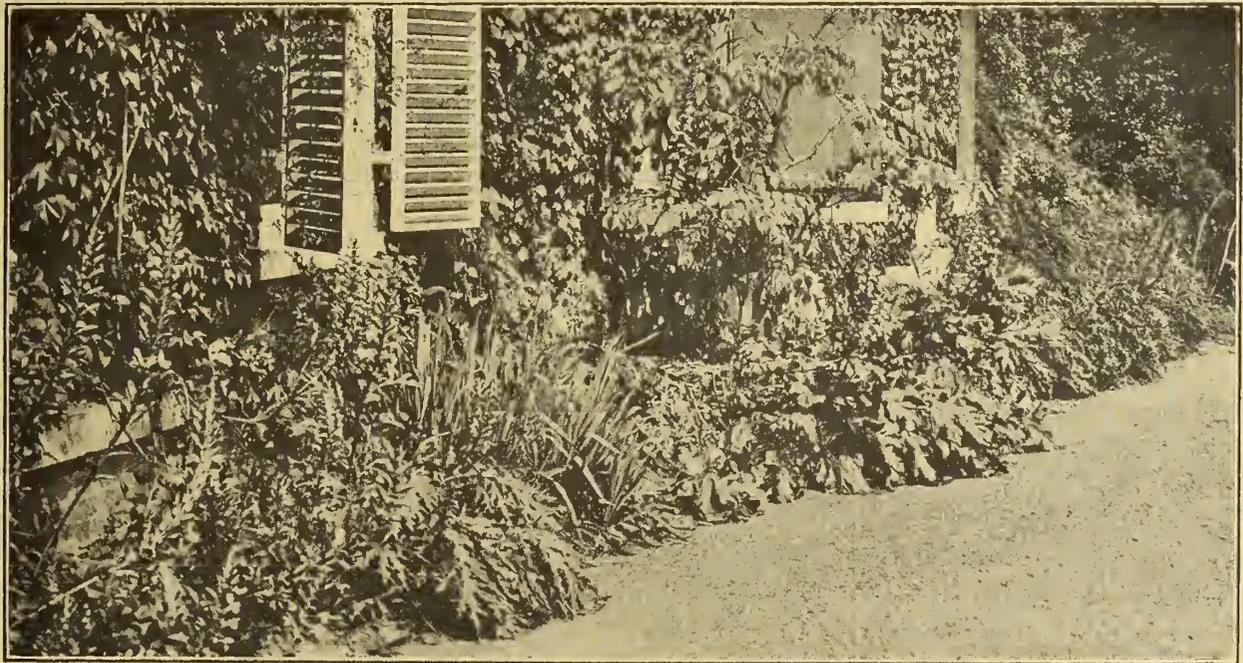

lustrous than the type, is very bold and imposing, the broader leaves less deeply lobed. The leaves of the typical kind are those usually represented in Corinthian architecture. A *Schotti* is probably but a synonym of the above.

A. LONGIFOLIUS, from Dalmatia, also attains to a considerable size, the leaves attaining 2 feet to 3 feet long, but even so, it lacks the characteristic ornament of the first-named. The green leaves are not lustrous. The pink flowers appear from spiny bracts of reddish colour.

A. PERRINGI, a smaller-growing, erect-habited species from Asia Minor. The flowers are pink. A comparatively modern introduction that is better suited to the border.

A. SPINOSUS AND *SPINOSISSIMUS*, from South Europe, are highly ornamental, the silvery effect of their spiny leaves adding a distinctive beauty. The flowers are purplish and rose respectively. I have not found that these flower with the same freedom as *A. mollis*.

A. CAROLI ALEXANDRI, a Grecian species,

Acanthus at Myddelton House.

reason of a contour which is practically unique, ill-suited to the ordinary herbaceous border, and should be either grouped or disposed in isolated examples, where their fullest beauty may be seen. This may well be on the lawn, in bold recesses in the rock garden where from a background of good rock their finer attributes would be apparent, or at the parting of ways in garden or woodland—anywhere, indeed, where scope for full development presented itself. In the herbaceous border, no matter what its size, this could not be. So large-growing a subject would, of necessity, have to go into the background, where but a tittle of the plant's beauty would be seen, and the gracefully arching leaves all but lost to view. Like the *Yucca* and other plants of outstanding character and distinction, these *Acanthuses* are best alone. Taking longer to establish than most hardy perennials and not lending themselves to frequent division are other reasons for not putting them into herbaceous borders which, from time to time, have to be replanted.

I wonder whether any gardener has ever

so since rather slow to establish. They dislike frequent interference. Increased readily by division and by seeds, the quickest and most prolific means of increase is by root cuttings secured and inserted in autumn. So readily and abundantly do they come from roots, indeed, that I have known a hundred or so result from the detached roots from lifting and dividing a solitary specimen. The other methods mentioned are slow. Where roots are required, enough may be secured by digging at one side of a clump, thereby saving the trouble of lifting and its weakening effects. There are not many kinds, those enumerated below being the best. The flowering period is August and onward.

A. MOLLIS.—I look upon this Italian species as the finest of the genus. When established, the arching, olive-green, lustrous leaves may each be a foot wide and a yard long, the plant isolated forming a clump 6 feet across. High above the deeply sinuated leaves tower the spikes of white or rose flowers, which, with the toothed bracts, are curious and interesting. Its variety *latifolius*, if a little less

is also very spiny, producing its flowers in somewhat globose heads. I have never grown it. E. H. JENKINS.

NOTES AND REPLIES.

Manuring hardy plant border.—I have recently undertaken the management of a large semi-public garden. Owing to war economies I have a difficulty in obtaining farmyard manure or labour. There is a long so-called herbaceous border with trees and flowering shrubs at the back and hardy perennials in front. I have had the greater part of this bastard trenched and replanted, but have not been able to add any nourishment. What chemical dressing could I apply during the winter and spring at a moderate cost? The soil is light, with a fair amount of lime, and has a gravel subsoil.—CAMBRIDGE.

[We regret you had not written us earlier or before you replanted the border, as we should then have advised you to give the soil—both spits—a good dressing of bone-meal, which can be purchased at a cheap rate. This you could have employed at the rate of 2 ozs. per square yard for both the top and bottom spits, and would have become more quickly available as a plant food next season than basic slag. It is,

however, not too late to apply a 2-oz. dressing to the surface, taking care it does not come into direct contact with the roots of the plants, and fork it in. The sooner this is done the better. When ordering, ask for best bone-meal, and do not accept bone-flour. In early spring apply $\frac{1}{2}$ oz. sulphate of ammonia and $1\frac{1}{2}$ ozs. superphosphate per square yard, and lightly fork or hoe them in. By measuring the length of the border and multiplying the result by the width you will obtain the total area in square feet. Reduce this to square yards, when an estimate of the total quantity of the manures required can then be quickly arrived at.]

VEGETABLES.

VEGETABLE NOTES.

EARLY POTATOES.—We may take it for granted that Potatoes will be dear next spring. Last year the Government commandeered the Jersey crop, the consequence being that the earliest tubers in this district made as much as 12s. per bushel, and as the same thing will, in all probability, happen again it behoves all who have the power to do so to make timely preparations for the production of an early crop of this indispensable vegetable. The ground for early Potatoes should be very free, and, if possible, a sheltered position should be chosen, but well open to the sun. It should be roughly dug, or, in the case of stiff soil, ridged up, so that it becomes thoroughly sweetened by frost. Ridging may be done at once, digging in February, but keeping a rough surface. If the sets are prepared by being put in single layers into boxes so that short, green shoots are formed, with embryo roots forming, there will be no need to be in a hurry, as in a few days roots will be entering the soil, whereas in the ordinary way the shoots have to form, which will make quite a fortnight's difference. Should the weather be inclement the soil perhaps frost-bound, the grower with these prepared sets has no need to worry, but can wait for the change. The experienced grower will choose the variety which he has proved to do well with him. Eclipse is much grown in this locality, and Sharpe's Express is favoured by many. Early Puritan I have found reliable, and May Queen is in favour now, but is not quite so early as Eclipse. The earliest Potato is, of course, the Ashleaf, and the true old Myatt's is probably still the best and most reliable, but do not plant this in cold, heavy land. The soil for it must be very free. Plenty of well-rotted manure or leaf-soil will promote a free growth. As is well known, the great enemy of the early Potato crop is the May frost, as the labour and expense incurred may be rendered useless in one night. Therefore, where it is a matter of a limited area some kind of protection should be afforded. A rough framework on which boughs, old Pea-sticks, or anything of a similar nature can be laid will make all the difference between failure and a valuable crop.

BROAD BEANS.—I remember the time when the sowing of Broad Beans in November for an early crop was generally practised, but I find that most vegetable growers nowadays defer sowing until February. I would strongly advise your readers to sow this year as soon as this note appears. This sowing will advance the gathering season by several weeks, and under present circumstances this early crop must prove very valuable. This should be succeeded by another sowing in February and another in March, so as to give as long a season as possible. In many

districts black fly renders the culture of this esculent precarious, and occasionally in a very hot, dry time the whole crop fails. It is impossible to grow field Beans here. As regards garden crops there need be no loss. When fly appears I syringe with XL All insecticide, somewhat stronger than in the directions, and in forty-eight hours the plants are thoroughly clean. By doing this I have a good crop of Beans when they have been a complete failure all round me. I do not know how the Broad Bean compares in nutritive value with the Potato, but it is a very satisfying vegetable.

PARSNIPS.—Those who have a good breadth of these may consider themselves lucky. The Parsnip will not, of course, take the place of the Potato, but it is a wonderful help when Potatoes are scarce. The Parsnip is the most easily grown of all vegetables, is not particular as to soil, and is immune, so far as I am aware, from disease. It is certain that a greater weight of food can be grown on the space by using the Parsnip than with any other esculent. We do not know how long this war may last. I, therefore, strongly counsel your readers to devote a fair breadth of ground to the Parsnip, which never under decent culture fails to yield a rich reward for labour expended.

BYFLEET.

GROWING TOMATOES IN GREENHOUSE.

I wish to grow Tomatoes in a span-roofed greenhouse 12 feet long; but, instead of planting them in 8-inch or 10-inch pots, I want to grow them in wooden troughs. Will you kindly inform me: (1) How deep and wide the troughs should be? (2) The right sort of soil? (3) The general culture of the Tomato? I propose sowing the seed in January and planting in March. Will you please say which sorts you consider best for this purpose?—NEMO.

[The troughs may be a foot in width and the same in depth. These should not be filled with soil at the start. At first just put in enough soil to cover the ball of roots of the young plants, then add as required as the season goes on. A suitable soil for Tomatoes is pure loam—that is, rotted turf, the more fibrous the better, and bone-meal at the rate of 2 lbs. to the bushel may be an addition worth while in aiding a solid, healthy growth. Press the soil down firmly; this assists firm rather than gross leaves and short-jointed stems. In rearing the young plants it is well to keep this sturdy growth in mind, because all too often they are brought on in a hot, confined atmosphere, and thus become drawn. Shelves near the glass may be suggested as being a good position when the young seedlings have advanced to a few inches high. Put out the plants 15 inches apart in the troughs and keep each plant to one stem throughout the season, rubbing out all side growths whilst quite small. In the matter of air there should be some care in cold weather; still, there are not many days on which a little may not be given—at least, if the sun is shining. As the spring advances so must there be more ventilation, with, of course, fire-heat at night. Artificial warmth may continue till the end of May; indeed, the plants and the crop of Tomatoes will benefit if there be a little heat in the pipes at night throughout the summer, except during a spell of very hot weather. Be sparing with water after planting up to the time the first truss of flowers shows, and use lukewarm water. As the season goes on there is not much danger in over-watering—that is, when fruits are swelling. To keep vigour and a crop right up to the last, stimulants must be given. Tomatoes are not particular as to variety, whether they be of the forms known as

"artificial" or "liquids" from animal manures. If plenty of air reaches the plants there should be no trouble about the fruit setting—or, rather, if warmth, air, and water combined are not stinted. By following the above items briefly put there should not be an over-abundance of leafage, the leaves themselves should not be of huge dimensions, and until the fruits are turning colour none should be removed. The points may be shortened, perhaps, and the lower leaves cut away. Proceed in this way the whole year—that is, take away the lower leaves as the fruits ripen, but leave undeveloped ones practically intact. Kondine Red and Ailsa Craig are fine varieties. These produce good-sized Tomatoes in abundance. Sunrise is ideal in shape, but by some may be considered rather small.]

NOTES AND REPLIES.

Celery disease.—As a subscriber to your valuable journal, I would like to get some information re a disease which has been very prevalent in this district (Navan) for the past three years. The disease is familiarly known as Celery-rust. Up to three years ago I used to pride myself on the fine Celery I could grow, but for the past three years, owing to this destructive disease, my Celery is a total failure. I consulted, some time ago, an eminent horticulturist from the north of Ireland, and he advised me that the disease came from seed. The seed the year mentioned came from a leading firm, but the following year I determined to change, and got my seed from another leading Irish firm, with exactly the same result. Last autumn I was staying with a friend, who was one of the best gardeners in the south of Ireland. I placed my grievance before him. He showed me some splendid Celery, and advised me to spray the plants thoroughly with spray used for Potatoes, but only half strength. Accordingly, when the plants were well established in the trenches last June I gave them a thorough spraying, and, acting on advice, I gave another thorough spraying in August, but I am sorry to say it was of no avail, and my rows of Celery are covered with the disease; in fact, the rows are nearly all rotten. I may state, every suspected diseased leaf was picked off before the second spraying was done.—H. J. CULLEN.

[You will find in our issue of December 5th, 1914, p. 786, a paper dealing fully with this trouble, which has spread very freely during the last few years. A copy of the said issue can be had from the publisher post free for 1½d.]

Food production and the garden.—The note at p. 610, over the signature of "I. Blackburn," is interesting, and certainly opens a way to the disposal of waste in the garden. But in a general way a couple of pigs can readily use up the surplus. What I meant, more particularly, was that increased production above the actual requirements of the establishment would lead to increased waste, and that, therefore, was to be deprecated. At any rate, I would hesitate to undertake the management of a Belgian-hare farm in addition to the work which already threatens to fall into arrears. The better way, as I indicated, is to plant only what experience has shown to be an abundant supply—that is, in cases where, owing to circumstances, the Navy or Training Camps cannot be benefited by the surplus. Nevertheless, there may be places where the advice tendered might be acceptable, and so far the writer is justified.—A SCOTTISH GARDENER.

Wood-ashes as manure.—The chief fertilising ingredient in wood-ashes is potash, and potassium carbonate being readily soluble in water must be kept dry till it is applied to the soil. It may be noted that small brush and foliage are far richer in potash than is large timber. Bracken, which is becoming a serious scourge on hill

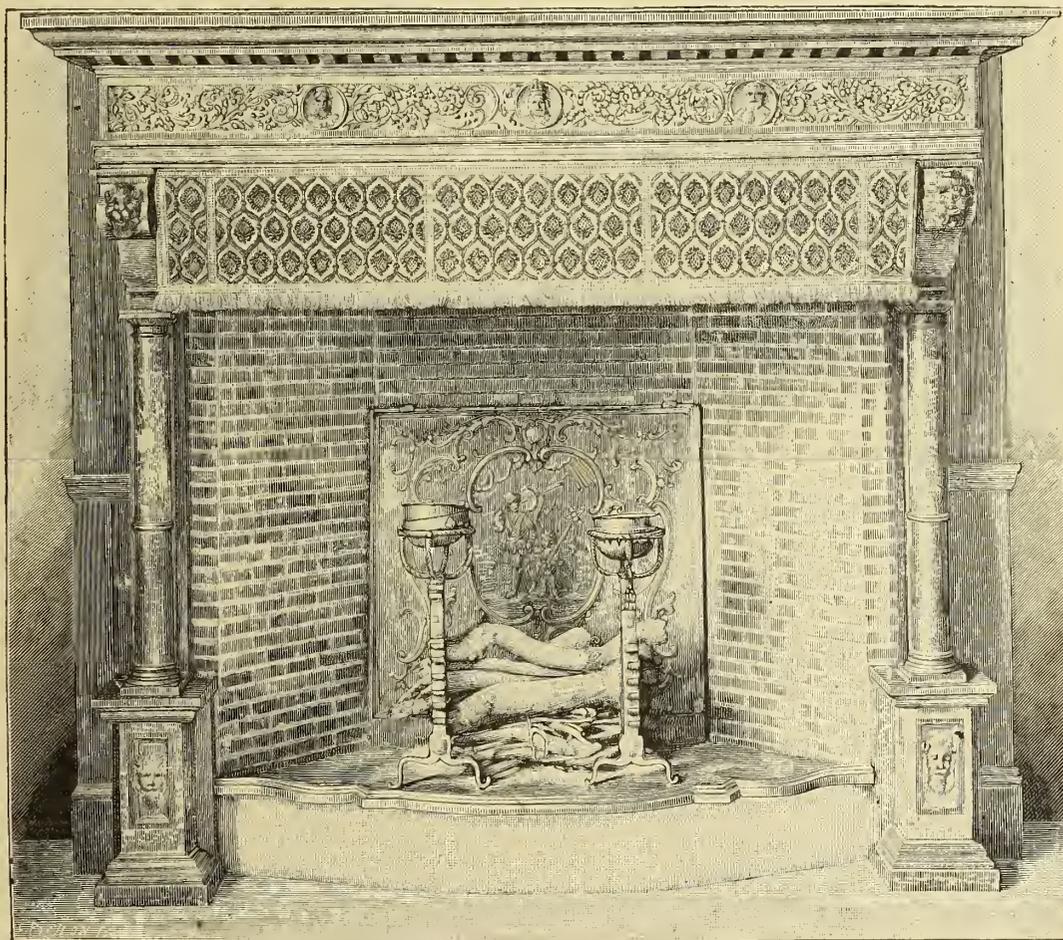

pastures in the North, contains much potash. I am informed that, if cut at mid-summer or in July, the ash returns 25 per cent. of potash, whereas if the Fern is left standing till August the proportion falls to 5 per cent. Here, I submit, is a promising field for experiment. If we could rid our pastures of Braeken and, at the same time, harvest a good supply of potash, we should be doing ourselves double service. Hitherto, I believe, British glass-blowers, soap-boilers, and farmers have relied for supplies of potash on the potassiferous minerals of Stassfurt in Germany. That source is now closed; the deposits in the Carpathian Mountains are not yet opened up. It would be well if we could produce this indispensable material at home. I believe there is already some revival of kelp-

in many households is worthy of more trouble than is usually accorded it. Earthing-up the plants with soil will do much towards helping them in a time of extended frost. Particularly is this beneficial in the case of plants that were not got into their permanent quarters until late in the autumn.—LEAHURST.

Spinach all the year.—I have met with many people whose experience of Spinach is confined to the growing of the Round for summer use only, leaving out of their account the Long Standing, which has a more extended season; the Prickly, which is in capital condition now (December 9th) from a July sowing; and the Perpetual or Spinach Beet, which is a splendid standby in any garden. Sown in succession, one may have a plentiful supply of this very useful vegetable. Those who are planning for next year's produce will do well to bear in mind Spinach, leaving space between lines of dwarf Peas, etc., for a few

THE HALL FIRE.

In our wet and cold country, even in the best parts, a good fire is essential in what in country houses is called the hall. Even in bad summers it is not amiss to have it, and the best of all fires is the wood fire. We speak for the country house and farm, where there is plenty of wood, and there is often stuff for cutting round almost every country garden, owing to past mistakes in planting rampant evergreens and trees out of place. Some people hesitate to cut down a tree whether it is rightly or wrongly placed. The mixed-muddle shrubbery is a great source of firewood—Willows, Poplars, Sycamores, put among Japanese and other foreign trees. There is a lot of firewood to be got from these clumps when old. Even the stumps of trees that are

Hall fireplace for burning wood only. Hearth, an iron plate raised 10 inches above stone floor; mantel, old Flemish.

burning in the West Highlands and in Ireland.—HERBERT MAXWELL in *Country Life*.

Disposing of garden refuse.—When manure and cost of carting are so expensive it is advisable to see what one can do with the refuse in one's own garden. Amongst vegetables there is always at this time of the year decaying foliage that should be collected, and if it is not decided to deposit it at the bottom of trenches for another year, the next best plan is to burn it; indeed, I do not know, when everything is considered, whether burning all garden refuse is not the best, as it is the most effective way of destroying slugs and other enemies that lurk in the soil, and the ashes from such fires are most useful when preparing beds for Turnips, Onions, Potatoes, and general garden produce.—W. F. D.

Spring Cabbage.—People in the North of England have sometimes told me that it is only in a mild winter that they can be sure of Cabbage for cutting the following spring, unless they afford protection. This vegetable

rows to be sown in succession, not forgetting to sow in July a good breadth for use from November onwards.—LEAHURST.

Stacking turves on allotments.—I have noticed that on new allotments some of the tenants have made a practice of stacking turves instead of digging them in. In some instances as many as four and six stacks are to be seen on one patch of ground. I am told that these stacks were made so that the turves would rot more easily, but it seems to me that it is altogether wrong, for they would decay just as soon if buried in the soil, particularly where the land has been trenched; and, what is of equal importance, the space they occupy might be put to better use with crops. It is true that some few of these heaps of turf have been used for growing Marrows. My experience is that to keep turves out of the soil is to rob it, besides which in a dry time, buried beneath the surface, turves help to conserve moisture. Those who are entering on new allotments should, when digging, work in the turves under the second spit.—LEAHURST.

grubbed out of the ground will burn in a well-made wood fireplace in a hall.

The essential thing is to have a good hearth. We see in illustrations of great country houses that the old down fire has given place to some kind of raised grate, mainly because the modern architect makes his chimneys much too narrow for a wood fire. In these you can never have a wood fire such as one wants for a hall. The hearth should be flat and raised 10 inches above the floor for the sake of a better draught. The main point, however, is that the chimney should be not less than 14 inches x 14 inches. As the hall is usually where there is no lack of air, it is seldom necessary to make special provision for air. In the one illustrated the room communicated with another hall and had several doors, so that there was no lack of a draught, but the architect had made the chimney much too narrow.

After much consideration I decided to rebuild the chimney, and since then I have had perfect fires in all ways. From such a fire the ashes should be removed only when they have nearly overflowed the hearth. They are excellent for lawn or flower-bed, and much better for that purpose than the ashes from a filthy coal fire.

W.

LAW AND CUSTOM.

EMPLOYEES OCCUPYING COTTAGES.

It is quite a common thing for persons engaging gardeners and farm labourers and similar employees in country districts to allow them, as part of their remuneration, to occupy a cottage and garden rent free. When this is the case difficulties frequently arise upon the termination of the employment, and I have frequently had enquiries as to the relative positions of employer and employee in regard to vacating a cottage. There seems to be a prevalent idea, especially among gardeners, that when they are allowed the use of a house as part of their remuneration their position becomes that of a tenant entitled to the ordinary notice to quit applicable to the tenancy of a cottage of that description. I have before me at the present time a case in which a farmer put up some cottages for his labourers, and one of them, on leaving the farmer's employment, refused to leave his cottage on the ground that, although he is no longer employed by the farmer, he is yet a tenant of the cottage and garden, and is entitled to have formal notice to quit and also to be compensated for improvements to his garden under the Allotments and Cottage Gardens (Compensation for Crops) Act. I need hardly say that this man is mistaken in his view of the legal position. It was decided in a case of this sort something like seventy years ago that an employee occupying a cottage belonging to his master is not a tenant and has no estate or interest in the premises, so that he may be forcibly evicted without the necessity for taking the ordinary proceedings to obtain an eviction order which are necessary when a landlord wants to evict a tenant who refuses to quit. The discharged employee may be turned out of his cottage at the same time as his employment is terminated, and his goods may be put into the high road without any liability on the part of the landlord unless it be a liability at the hands of the local authority for obstructing the highway, against which, of course, he must be careful to safeguard himself by not putting the goods in a place where they would be likely to be regarded as an obstruction.

There is, however, another side to the question which needs to be kept in view. A gardener or other employee is, of course, entitled to proper notice to determine his employment, and if he is discharged without that proper notice he has a right of action for damages. Imagine a man employed as a gardener or coachman entitled, according to custom, to a month's notice being suddenly discharged from his employment and being turned out of his cottage at the same time. Unless that action on the part of the employer could be abundantly justified the man would be entitled to take into account as part of the damages recoverable the loss he may have been put to by suddenly being turned out of the cottage, because it is quite a reasonable supposition, though I cannot at the moment find any case in which the point has been decided, that a man entitled to a month's notice who, as part of his remuneration, has free occupation of a cottage should be entitled to continue in

occupation of the cottage at all events until the date of his employment expires by effluxion of the notice given.

BARRISTER.

Dangerous trees (Hugonot).—We quite agree with you in the view you express that, inasmuch as your neighbour had ample warning of the dangerous state of his trees, he ought to have taken steps to prevent this mischief from happening, as it was bound to do sooner or later. He appears to us, therefore, to have been guilty of negligence, and, although we should not like to predict a successful issue to litigation, we think it is quite likely that if the law on the subject were tested it would result in your favour. It is, however, an open question, and as you do not feel disposed to go to the expense of testing it the only advice we can give is that you should instruct your solicitor to apply to your neighbour for compensation and give him further warning in regard to the dangerous state of the other trees. Possibly, rather than face litigation, your neighbour would be willing to compromise.—LEX.

THE ROYAL HORTICULTURAL SOCIETY'S TRUE WORK.

The following letter, signed by the secretary, has been sent, in the interests of the Society, to a Fellow of the Royal Horticultural Society, who had sent in his resignation, together with a statement of what the Society has done of late, some of it not wisely:—

At their last meeting the President and Council of the Society had before them a statement showing the numerical position of the Fellows, when they noted with regret that for the first time since 1888 there has been a considerable decrease, the number of resignations being particularly heavy. Whilst, doubtless, this is due to the war, this old-established British Society was committed to a certain annual expenditure before war broke out wherein retrenchment is practically impossible. All possible economies are being introduced with a view to the demands upon Fellows being reduced as far as possible, but if this process of resignation continues the Society before long will be faced with grave difficulties. I am therefore writing to ask you earnestly to consider allowing your name to be reinstated on our list.

POSTSCRIPT.—*May I add one personal word? I have devoted the twenty-eight best years of my life to building up the old Society, and I do hope the Fellows will help at this difficult juncture to prevent it from again falling back into the derelict state in which I found it in 1888.*—W. W.

The secretary does not mention the rebirth of a true taste for gardening as a cause of the Society's past success. He is now doing all in his power to get the Society back into a bad state by costly and useless experiments at Wisley, bringing the Fellows of learned Societies to take the place of good gardeners. If our Agricultural Society were so unwise as to have a farm of its own, what would be thought of it if it put a Fellow of the Royal or Linnean Societies in charge? The reverend gentleman, like so many who waste the best years of their lives at a university, is led to put words before things, and to suggest professors of wordy futilities instead of experiments on the ground that all might see the value of.

One of the great mistakes the Society makes is in arranging for

TRIALS OF SLIGHT VALUE.

The true way for the Society is to make the gardens of these islands an experimental garden. In every county there are people who would be happy to make trials with slight cost to the Society. Often in such places we find better conditions for carrying out trials than there are at Wisley. Trials of Peas and Beans are carried out already by seedsmen and private growers, and there is no need for the Society to make them. The right way with any trials worth making is to follow the French method—that is, to send out trustworthy men to report on trials made by others. These trials are, as a rule, made under better conditions than the Society can command.

The learned Fellows who are supposed to manage this garden, which, observe, was meant for gardening only, are a director, a Fellow of the Royal Society, a head of the school of horticulture, a professor of entomology, a professor of chemistry, a lecturer in botany, an hon. researcher in electrobiology. It is clear that none of these things has much to do with the true work of the Society. In all our great universities there are professors of such chemical or biological studies who would be willing to undertake the solving of problems the Society might put before them. It is folly having a professor of botany for a small place in Surrey when the finest botanic garden in the known world is in the same county at Kew. It is a serious mistake not to distinguish botany from gardening, the former a world science, and gardening a practical question that must arise out of the ground and in any country and its soils, climates, and varied conditions.

No word herein is meant to the detriment of any of these gentlemen, who are learned in their own ways—it is the foolish policy of putting them in the place of a trained gardener, and is part of the folly of mistaking botany for horticulture. If the Society has a garden, it should be managed by a gardener like the late George Nicholson, of Kew. Gardening has now so many branches that it is a serious labour for a youth to master them, and the prizes in the art should go to the best men trained to it, and not to professors of things wholly distinct.

VALUE OF THE GARDEN.

The garden is a mistake as managed. Some who have thought much of the matter say that the right way for a garden society in a centre like London is to have a good house and a full library. This is proved by the prosperity of the great central societies of France and New England. No great garden has ever been well managed by a committee.

All the most inspiring and the best gardens of our own time were managed by gardeners like Moore, of Dublin, McNab, of Edinburgh, and others, for whom the garden held the first place, and botany and other sciences came afterwards. Amateurs like Thomas Hanbury, and enterprising nurserymen like the Veitchs, with their brave travellers from Lobb to Wilson, had their heart in the work. In France, the most splendid thing done for our open-air gardens was the raising of the finely coloured Water Lilies—not the work of an academician, but of a modest amateur in a small town near Bordeaux. Gardening is an art of observation, like soldiers', sailors', and farmers' work. The idea of learning it thoroughly in a college or in any way but through the work itself is a delusion.

We find an example of the futility of the Society's laboratories in a report on

inoculated peat invented by Professor Bottomley. After several pages of the report, in which we are told nothing, the writer says the inventor of this peat has not revealed its nature. Here is a case of a learned society experimenting with a substance of the nature of which they are in ignorance. Any experiment that is thought to be of real importance for the country garden should be tried in the open garden. It is only fair where objection is made to the management of the Society to speak of the work that it should do when it has a garden.

IMPROVED FRUIT CULTURE.

The stocks for fruit-trees used by the trade should be looked into carefully as regards their results, and the stocks some of our best Apples are worked on might be tested in a Society's garden. Thus an Apple like the Ribston, now neglected, should be shown grown on the different stocks that nurserymen sell it on, when it would be seen whether these stocks varied among themselves, as some suspect, or not. What the definite effects are of such stocks should be carefully studied from trees planted side by side. The Crab is the stock for the standard Apple, but whether it is the true wild Crab or some chance Apple seedling that is often used in nurseries is important for us. Judging by the weak trees often sent out, the point is open to doubt.

Take a single fruit—a noble one, too—the Apricot. For generations this has been rarely seen in good health in gardens, and why? It is not on its natural stock, the wild Apricot, but is grafted on the Plum. Before we can get over that evil it should be tested by the Society on its natural roots and on the wild Apricot, and seedlings should be raised from the best varieties to see if this precious fruit can be grown in health in our own country. It has been dying away in most gardens for many years.

GRAFTING AND ITS EVIL EFFECTS.

Few know the amount of harm that for generations past has been done in our gardens by grafting. That should be worth the care of a society with a garden, and no other body could do it so well, because it could put side by side in its gardens trees on their own roots and grafted trees. It would be well within the work of the Society to have its own garden examples of trees grafted and trees on their own roots raised from layers or cuttings. The harm of grafting ornamental trees is enormous, and in the case of fruit-trees there is much working in the dark. All the stocks in use should be put to a thorough test, and in all cases tried under the same conditions as the tree on its own roots from cuttings, layers, or seeds.

INFERIOR KINDS OF FRUIT.

Many frivolous pretexts are given for the founding of societies, but there is good work as well as bad in such, and the best is that of the Pomological Society of France, which prints a standard list of fruits, revising it from time to time, admitting only the best and discarding inferior kinds. The greatest drawback to British fruit culture is that there are too many kinds alike equally useless for the market and the home. In America anyone who observes what is being done in the orchard will find a man planting enough Newtown, or what good Apple it is that thrives in the locality, to get a supply of fruit for the market or other use. In Northern France, too, if one sees a good south wall in the garden, the chances are that it will be covered with a

fine Pear easily sold at a high figure. Confused by the voluminous lists in catalogues, our people go on planting poor kinds not good to eat or sell.

THE PEAR.

A large area of England and Ireland is admirably suited for the growth of this most delicious fruit of the northern world, but owing to the almost total neglect of the tree in its natural form of a standard on the natural stock, our gardens are robbed to a great extent of it, and there is not one-fourth of the production of the best Pears that there ought to be. There is so much use of stocks like the Quince that do not allow all good varieties of the tree to grow well, and so much stupid work in pruning that very few country places can show a good collection of Pears in their fruit-rooms. The greatest mistake is the neglect of the natural form of the tree.

The trade fruit catalogues are overdone and are very often compiled by men who have not tasted the fruit, as fruits that have not good quality are praised. The Society should control this by making a standard list of fruits into which no sort which is not proved to be of first-rate quality should enter. To reject the bad is as needful as to select the good. That Controlling Committee should be composed of growers and of those who eat and pay for the fruit, and the fruit list should be revised every three years.

THE APPLE AND ITS FUTURE IN THE BRITISH ISLES.

This, the noblest fruit of the North, deserves our best care, but our growers are so confused with too many kinds in catalogues and exhibitions, in which at least fifty kinds may be shown out of season, that it is impossible to determine which are the best kinds for general use. Americans and Colonials are not so mistaken as we are, and send us vast quantities of their best kinds. As fine might be grown in the warmer parts of Great Britain and Ireland, for some of our Apples are as good as any grown in the northern world, and, moreover, they have the merit of freshness. The energy that should carry us through to good crops is dissipated by growing too many kinds. What might be done by the Society, if we had a good one, would be the encouragement of the growth in orchards of one of each of the best kinds of Apple, such as, say, Blenheim, Ribston, and Sturmer.

Growers should be encouraged to make an orchard of one such standard kind, of which we cannot well have too many. When we grow a first-rate kind in quantity all that concerns it is better attended to—culture, cleanliness, and gathering. We should promote the natural form of the tree, far too much attention being now paid to dwarfing stocks and fooling ways of pruning. Over-pruning and bad pruning are far too common, reducing the amount of fruit and doing infinite harm. A rigid choice of kinds should be made. Diseases are far too rampant, American blight worst of all. With our present knowledge of washes we should be able to control these. In this way our own growers might compete with those of any country, but never so long as we cultivate a great number of poor kinds.

Now our Horticultural Society leads to mistakes by encouraging the exhibition of many kinds often out of their true season of use. We can never compete with the Pacific coast and other growers without a complete change of system; and growing well such fruit as Ribston, Blenheim, Sturmer, Roundway, Bramley, Alfriston, and Wellington orchard fashion, would be

far better worth cultivating than the numbers of kinds we now have.

Some control of the issue of new kinds might well be in action. Of recent years new Apples have been sent out which are no improvement on old kinds (some quite inferior). This evil might be lessened if we have a revision of a standard fruit list every three years, as is done by the Pomological Society of France, with power to exclude from it any worthless new kinds arising from time to time. Controlled in that way the trade would be more cautious about bringing out new kinds before they were well tried.

EXAMINATIONS FOR GARDENERS.

The Society has issued a printed statement about examinations being held for gardeners. It is a movement for bringing young gardeners into the folly of examinations with doubtful results. Colleges may be essential for chemists, doctors, and other technical professions, but gardening is a work to be learnt only in the open air. There is so much to learn, and so much variety of garden to be studied, that little time could be spared from it for passing paper examinations and storing the memory with facts that have little to do with the work itself. Men with a faculty for memorising books only will arise. Many of the best gardeners would not be able to pass an examination, nor would they be any the better gardeners if they could. The gardener has much book matter to avail himself of in the current papers of the day, and he must be to some extent dependent on books for his instruction. But in addition to such sources of knowledge, to attempt to cram him with lore which examiners may expect of him is a mistake.

The old way of teaching gardening by several years' apprenticeship was the right way. It was in that way also that the great painters were taught their art, and not by the multiplication of academies and lecturers. There never were so many critics, teachers, academies, and exhibitions as in our day, but ask the opinion of the men wisest about good pictures in London or Paris, and they will tell you that no good work is being done. The artists think more of how the work will look in an exhibition than of the thing itself, and they talk of "expressing themselves" in their work, an idea which the old masters never thought of. If anyone doubt this view, portraits by Rembrandt or Franz Hals or other masters of their day will give proof that the old way was by far the best. Now, between expressing themselves, as they call it, and working with the show in their minds, they give us the academy daubs we are too familiar with.

The Society might well give its sanction and authority to a revival of apprenticeship as the only sound way of making a good gardener. There are several colleges now which profess to teach gardening without having any good means of doing so. It can only be taught to a boy by means of the varied work of a good garden; afterwards by working as a journeyman in a succession of good gardens.

THE LANDSCAPE GARDENING ART.

Various sorts of men and some nurserymen now advertise as landscape architects, even if they have not had the slightest training in cultivation or design. That cannot do any good. The business training for a nurseryman is quite distinct from that required for a landscape gardener, which should embrace much study of trees and hills and valley landscape beauty in wild lands as well as in our planted country. No training will make a man an

artist who has not got it in him, but some attempt might well be made to prevent seedsmen and others with no knowledge of trees and shrubs from calling themselves landscape artists.

Economy in working gardens of all kinds is so important that designing is best done by men who have been trained in garden work. Therefore young men who have been first trained as gardeners would be the best to put to the study of design. This was so with Marnock, Fraser in Ireland, and André in France, who all began as gardeners. A good way to encourage promising young men would be to give them opportunities for visiting the mountains and valleys of Central Europe and other lands of beauty. They would learn more in that way than any book could teach them. There is

CHAOS OF NAMES OF VEGETABLES.

Every seedsman, big or little, calls each Potato or a Bean after himself, so that foreigners and others find it quite impossible to know the difference between new things and old, and have to waste much time in trials. This should be changed, and all the old vegetables that were raised in France, England, Italy, or other countries should be known under their true names.

It is in the interest of all that a vegetable grown for many years around Naples or Paris should bear its own name. Also the old sorts of our own country should bear their true names and not be the victims of re-baptisings. A standard list of the best vegetables would be well worthy of an effort. The trade are working against themselves in attaching new names to all. If they raise a good thing no one can now tell whether it is really theirs or an old one re-named.

COOKING VEGETABLES.

From the point of view of health and economy we are every day becoming more alive to the importance of food from the garden, and no pains should be spared to issue a good standard list of all the kinds worth growing.

The climate of our islands is more favourable to the production of excellent garden food than that of any other country of Europe, and therefore the importance of the right cooking of such food is great. For generations the cookery of vegetables has been a disgrace to English houses and even restaurants. Much of the value of vegetables is lost in water, and a most useful work the Society might undertake would be the production of an essay of sound information as to the cookery of the vast mass of vegetable food grown in our islands. Such a work should have passed through the hands of real cooks, as the value of vegetable food, much in question in our day, depends greatly on the cooking of it.

CONTROL OF BAD TRADE PRACTICES.

In our islands much harm has been done to horticulture by fixed practices of the trade. This is a large evil that has lasted long, and nothing will cure it if the cure is left in the hands of the trade. The nursery trade is occupied in the production of young trees and plants the final growth of which they rarely see. It is difficult to give an idea of the evil done by various modes of propagating, though certain drawbacks stand out clearly. Our islands have been cleared almost of the most beautiful flowering climber of the northern world, the Clematis, by the stereotyped way of increase, grafting the Chinese and Japanese plants on the common wild Clematis of the hills, as I have proved in

my own garden. The splendid series of Rhododendrons raised in England has been half lost by grafting on the Pontic kind, the result of the practice being that the stock destroys the graft and we get too much ponticum all over the country. The many lovely kinds of Lilac raised on the Continent in recent years have been lost by grafting on the wretched Privet, which in due course takes the place of the Lilacs. Beautiful evergreens of value, like Phillyrea Vilmoriniana, grafted on the Privet died in hundreds. The Hawthorns of the northern world, many quite distinct from our native one, both in fruit and flower, are lost by grafting on our native thorn, which in due time kills the kind we hoped to enjoy.

To go from precious flowering shrubs to fruit-trees, let us take the Apricot. For generations this has been thoughtlessly grafted on the Plum, with the result that the trees are, in most gardens, on the way to death. If we ever have a garden society worthy of the name, with a garden of its own, all these practices should be tested. The public has to await the result, and, as it often ends in disease or death, the whole thing is soon forgotten, and the cause often wrongly attributed to the climate and not to a wrong mode of increase.

Large areas of poor land are bare of Roses because the trade will only give us the Rose of whatever nature worked on the Dog Briar, on which many of the finest Tea Roses perish or dwindle away.

These and like evils might be shown, with the remedy, in the Society's garden, where the public might see results not open to all in private places. Therefore the first thing any healthy garden society should do should be to free itself of all trade control. Healthy control through and for the public would in the end be for the good of the trade itself. It should be clear to all who give any thought to the subject that the loss of a noble family like the Clematis can do no good to the trade as the public cease planting.

REFORM OF NAMES.—Control of confusing synonyms and false names might well be worth striving after in the case of fruit and vegetables. Bringing out old varieties under new names is a practice that should be stopped. False naming, like Horse Chestnut applied to a tree (rightly Buckeye) that is quite distinct from a Chestnut, Artichokes, so-called, that in no way resemble true Artichokes, and wrong names used in market (Grape fruit), all these and the like might well be stopped as confusing to the beginner. Re-naming foreign fruits is not unknown with us, and, whether done by mistake or otherwise, it is a bad practice.

The confusion and wasted effort, owing to every seed merchant calling every vegetable after himself, are deplorable for the foreigner, colonist, and even for the gardener and amateur. Therefore, a standard list of the best vegetables throughout Europe would be a great gain and worthy of the best efforts of a garden society. Such a standard list would not be in any way against real novelties, which might rightly bear the raiser's name.

The Society is ill-advised to build a laboratory costing over £20,000 for experiments of doubtful value. This is done on land not their own, lent to them by the late Sir Thomas Hanbury for purely garden work. The land is not suitable for fruit culture, on which we want more light than on any other gardening question. If a garden is wanted for such work it should be in the best land, where useful examples of good fruit culture might be shown to all interested.

A LIFE FELLOW.

PERPETUAL-FLOWERING CARNATION SOCIETY.

THE exhibition, which took place in the Royal Horticultural Hall on December 6th, was the twenty-first held by this Society. Owing to shortage of labour and difficulties of transit it was also one of the smallest. For example, no entry was received for the Monro Challenge Cup Class, or for the Brunton Challenge Cup, the former the most important of the whole show. Only one exhibit was staged in the American Novelty Class, the prize being given by the American Carnation Society, while in some other classes there was little competition. For the group class, amateurs' division, for pot-grown plants no entry was received. This, seeing its teaching value and importance, was unfortunate. In short, the entries were only about half the number of last year. This notwithstanding, excellent quality flowers were staged in most of the open classes, the trade growers, chiefly from the Hampton district, coming out strongly and well. No new feature was remarked in the table class or any originality displayed in those set apart for baskets or epergnes. Three new varieties gained Awards of Merit, one only of which, Red Ensign, appealed to the majority of those present. Brief particulars of the show are appended.

SECTION A.—OPEN TO ALL.

Messrs. W. Wells, Limited, alone entered in the American Cup class for three vases of novelties distributed since January 1st, 1913, showing Aviator (a fine scarlet), Peerless (cerise), and Enchantress Supreme, the last very good. The first prize was awarded. The class for five vases of Carnations, five varieties, twenty-five blooms of each, was contested by two Hampton growers, Mr. W. Sherwood taking first prize with a set comprising Beacon (clear rich scarlet), Enchantress Supreme, White Enchantress, Triumph (maroon-crimson), and Mr. C. W. Ward (a leading variety in the cerise class). Good, all-round produce, and well displayed, this merited high praise. Mr. H. T. Mason was a good second, his flowers more erectly disposed, being also less pleasing from the decorative standpoint. Warrior, a maroon-crimson raised by the exhibitor, was unmistakably the finest thing, though the rich scarlet Beacon was also good. Subaltern, another seedling of deepest cerise tone, is of much promise. This shade is much in demand in winter and tells to advantage under artificial light. Mr. W. H. Page led in the class for three vases of Carnations, conditions similar to the last, his vase of White Wonder, adjudged the best in classes four to ten inclusive, being awarded the silver-gilt medal in consequence. We do not remember to have seen finer blooms. His other varieties were May Day and Philadelphia. Messrs. Wells, Limited, were second, staging White Wonder, Aviator, and Lord Kitchener. We think highly of this last among the deep pink varieties, but the firm have shown it much better than now. In the single vase classes Mr. H. T. Mason took the first prize for both white and crimson, employing White Perfection and Warrior respectively, the latter in every way excellent, Messrs. Wells, Limited, scoring equally in those for scarlet and pink varieties, staging Aviator and Pink Perfection. In three of the four classes named only one exhibitor staged, the flowers being excellent.

SECTION B.—GENTLEMEN'S GARDENERS AND AMATEURS.

An important class here is for six vases of Carnations, six blooms in each, six varieties, the first prize going to Mr. W.

Heath (gardener to Sir Daniel Gooch, Bart., Hylands Park, Chelmsford), who showed Mrs. C. F. Raphael, Triumph, Gorgeous, Mary Allwood, White Enchantress, and Enchantress Supreme very finely. Mr. G. Lloyd Wigg, Merstham, was second, his premier vase being R. F. Felton (pink), others of merit being Snowstorm (a very good white) and Aviator (scarlet). This exhibitor alone staged three vases of eight blooms each and three vases of six blooms each, and was awarded first prize with good produce. Mr. G. Lloyd Wigg was also a most successful exhibitor, securing no less than four first prizes for single vases of blooms, the vase of Mrs. G. Lloyd Wigg, a magnificent pure white, gaining the special prize, a piece of plate, offered by Messrs. Wells.

NON-COMPETITIVE GROUPS.

For a magnificent group of Carnations—the outstanding feature of the show—Messrs. Allwood Brothers were deservedly awarded a large gold medal. The firm staged a very considerable collection of the best commercial sorts in exemplary style, the cultivation of the flowers also demonstrating high excellence. Arranging a big centre of some eight or ten amply-filled vases of Wivelsfield White, an indispensable in its class, the remaining varieties, arranged usually three vases of each, contributed to as fine a display as could be conceived. In this way such novelties as Nancy (pink), Destiny (cerise), Nora West (pink), Wivelsfield Wonder (an advance in white ground fancy sorts), Bishton Wonder, Salmon Enchantress, Enchantress Supreme, and others were seen to advantage. Only rarely do we see such fine quality blooms so simply and effectively disposed. In colour distribution there was not a discordant note throughout. Messrs. Stuart Low and Co. secured a gold medal for a much smaller collection, Alice (a pink-flowered novelty) and Pocahontas (crimson) being among important novelties in the group.

THE WEEK'S WORK.

OPEN-AIR GARDENING.

IN BLOOM DECEMBER 13TH.—*Andromeda floribunda*, *Escallonia montevideensis*, *Laurustinus*, *Jasminum nudiflorum*, *Correa magnifica*, *Veronica* (in variety), *Rosmarinus prostratus*, *Erica carnea*, *E. mediterranea hybrida*, *Winter Heliotrope*, *Helleborus niger*, *Iris stylosa*.

THE WEEK'S WORK.—During the past week there have been continual slight frosts at night, with fog, rain, and sleet during the day, which have made the ground very sticky and unfit for planting. All plants of doubtful hardiness have been well protected, as described in previous notes. The work of cleaning shrubberies and clearing away worn-out and weedy shrubs can be done in almost any weather, and this work is being proceeded with. Many evergreen shrubs and Conifers are benefited by the removal of superfluous branches. Although the present time is not the best for pruning shrubs, yet where shrubberies are numerous much of the work must perforce be done during the winter. The ground should be thoroughly cleared of all weeds, especially such as Nettles, Woodbine, etc., which accumulate in neglected shrubberies. Straggling plants of any common shrub should be cut down and the roots grubbed up, taking the opportunity thus provided of improving the soil by trenching it, and, if it is of a heavy nature, working in plenty of decayed leaves. One often sees in gardens uninteresting groups of Laurel, Yew, Box, etc., where the choicest and most interesting shrubs would thrive if properly planted. When preparing the ground for choice shrubs, if the soil is of a cold, retentive nature, it is advisable to form the beds above the level of the surroundings, and to plant only when the ground is in a suitable

condition. There is a wide selection of beautiful hardy shrubs that will succeed in any part of the country, and these can be procured at a reasonable cost. Beds of the Moccasin-flower (*Cypripedium spectabile*) have been given a good top-dressing of decayed manure and leaf-soil. It has been necessary to afford protection from birds to beds of *Polyanthus* to ensure a good supply of bloom for the spring. Small birds especially are very destructive, and will pick out the buds as fast as they appear. *Correas* are flowering magnificently planted in a sheltered position in the rock garden. They are afforded slight protection from frost. *Pernettyas* are very bright, and a few groups scattered here and there make a pleasing display, but birds have commenced to take the berries, and I fear will soon clear them. F. W. GALLOP.

Lilford Hall Gardens, Northants.

SOUTHERN COUNTIES.

Pruning.—After Morello Cherries, the pruning of wall-trained Plum and Pear trees should be taken in hand, as the weather being cold, the carrying out of the necessary amount of training, nailing, and tying, as the case may be, can then, by reason of the more favourable aspect of the walls against which they are grown, be more comfortably performed. Fully-established trees of the first-named should have the spur-wood shortened to four and five buds, and thinned also, getting rid of the weakest of it if it is at all crowded. This, though oftentimes reducing the crop as far as numbers are concerned, enhances the size and quality of the fruit that is yielded, and tends, at the same time, to maintain the trees in a healthy bearing state over a greater number of years, as it proves a sure check against over-cropping. Where the spurs have become overcrowded they should be judiciously thinned, either cutting them clean out or to within an inch or so of the main branches, so that new growths may in due course push out from these "stumps" and form the foundation for a new set of spurs. After these come to bear fruit the oldest of the remainder may be dealt with in a similar manner. By a continuance of this method the trees, if healthy, can in course of time be refurnished with new spurs. Very old trees are not worth this trouble, and should be grubbed and new ones planted in their stead. In the case of younger trees, the wood laid in during the past summer should be shortened as far back as the circumstances demand, taking care that this is done at a point where there is a wood-bud on the upper side of the shoot near to the wall, and not where a bud looks outwards or at a right angle to the wall. The observance of this rule makes all the difference when the new growth has to be trained in, as well as to the future appearance of the trees.

Pears.—Whether the trees are trained in the form of a fan, diagonally, or as cordons, the pruning of spur-wood is the same—i.e., the wood should be cut back to four buds, and the spur-wood thinned out if at all crowded. This is really of greater importance in the case of Pears than with Plums, as fine, well-developed fruits may be looked for in vain if the spurs are allowed to become congested in the manner indicated. The reduction of the number of spurs on the branches to more reasonable limits when there is a super-abundance of them is also very essential, and should be attended to at the same time. With regard to young trees, the wood laid in to form future branches in fan-trained examples must be cut back to where it is firm and well ripened. In that of diagonal-trained trees it should be shortened in like manner and to an equal length on each tier of branches and the leader, so that when the three uppermost buds break and the growths extend the two lowermost will form a new tier of branches at the right distance apart from those beneath them. The leaders on cordons, if well ripened and space available, may be left nearly full length. With respect to newly-planted trees of the foregoing, the pruning and fastening of them back to the wall should be deferred till February next. Anything in the shape of nailing and tying done now should be of a provisional nature only. Where cordon Pears are made a speciality of, the alley should not be less than 3 feet

in width at the foot of the walls, the whole of it being devoted to the roots of the trees. By careful attention to feeding from the surface, and affording a top-dressing of new compost every two or three years, the roots are not only kept near the surface, but from encroaching on the border beyond to any great extent. Now is the time to top-dress where it is required, and for which the best materials obtainable should be employed. To prevent this from becoming trodden into a compact, impervious mass while pruning and nailing are going on boards should be employed to stand upon.

Training, etc.—With regard to this, the young wood and branches should be trained out as straight as possible whatever the form of training may be, and no more shreds and nails employed than are necessary to make them secure to the face of the wall. Tarré twine is the best material to use for the fastening back of the larger branches and soft twine or "fillis" for those of less dimensions when the walls are wired.

Selection of scions.—If the re-grafting of any trees with a particular variety or with several varieties is contemplated, the scions for so doing should, before pruning is begun, be selected, labelled, and heeled in under a north wall.

Jerusalem Artichokes.—The tops were cut down some time since, and the crop—a good one—is now being lifted. Medium-sized, well-shaped tubers will be picked out for next season's planting and put away in a cool place. The largest and best will then be stored for the winter, and the remainder boiled up for pigs. The ground which will be required for other purposes will be well manured and bastard trenched.

Gas-lime.—Where a dressing of this is needed for land infested with wireworm and other insects and on which Brassicas and Turnips are subject to clubbing and the "finger-and-toe" disease, the same should be applied and dug in at once. It is always safer to use this material in a not too fresh condition if the ground is required for cropping early in the season. A medium-sized 60-sized potful in a fine condition to each square yard will prove an ample dressing if it is applied at once. The lime should be mixed as intimately with the soil as possible.

Parsnips.—In case of a prolonged frost setting in, enough roots to keep up the supply for a few weeks to come should be lifted and stored.

Seakale and Asparagus.—A regular supply of both must be maintained by introducing a sufficient number of crowns of the former every week or ten days to the Mushroom-house, and in the second case by making up a fresh hotbed in time for the crowns to be planted in a frame placed thereon before the supply in that now being used becomes exhausted. A. W.

MIDLAND COUNTIES.

All Vines that have cast their leaves should now be pruned and the houses and rods cleaned. At least one month should elapse between the pruning of Vines and the time that they are started into growth. The houses should be kept as cool as possible without admitting frost, as they will then start more freely into growth when the time for forcing arrives.

Cucumbers require special care at this season. Avoid over-cropping, and do not allow any decayed leaves to remain upon them. Give careful attention to watering, and apply an occasional light top-dressing to the roots, maintaining an atmospheric temperature of from 65 degs. to 70 degs. A sowing will now be made to provide plants to replace the old ones now fruiting. The seeds are sown singly in thumb-pots filled with a compost of fine loam and leaf-mould in equal parts. The pots are plunged in a hot-bed where the temperature is about 80 degs., and a sheet of glass placed over the top. As soon as sufficient roots have formed the plants will be transferred to 3-inch pots, and remain on the hot-bed near the glass until ready for planting out. The earliest batch of

Begonia Gloire de Lorraine having passed out of bloom, the spikes have been cut away, and the plants will be afforded a short season of rest, after which the growths will be shortened to about 9 inches. Following this they will be placed in a house having a warm, moist atmosphere and be sprayed frequently to induce them to make growths for the supply of early cuttings. Later batches of this *Begonia* are still in full beauty. The earliest batch of

Primula sinensis is now developing the flower-spikes, and is afforded a light position in a house where an atmospheric temperature of 50 degs. to 55 degs. is maintained, ventilation being given when the temperature reaches the latter figure. If the plants are strong and healthy, occasional applications of liquid-manure or a little approved fertiliser will encourage the spikes to be thrown well above the foliage, thus enhancing their beauty to a great extent. It will also help to keep the foliage of a good colour and ensure a succession of bloom.

Hippeastrums (Amaryllis).—I have often heard complaints of these failing to flower. Keeping them too dry whilst at rest and allowing the bulbs to shrivel are often the cause of this, though during the autumn and winter months (after the growth has ripened) no more water than is necessary to keep the bulbs plump should be given. The stock of bulbs should now be overhauled, selecting from them any that are beginning to develop their flower-spikes, removing these to a temperature of 55 degs. to 60 degs. The dry soil about their roots should be well soaked with water, and the atmosphere of the house in which they are placed should be kept moist by syringing. Stimulants afforded carefully will promote a robust growth, but in no case apply it unless root action be free and healthy. Those bulbs that have been longest at rest will produce their flower-spikes the first, and it is wise to periodically inspect the stock.

Autumn-planted Cabbages have made very free growth, and in the event of very severe frost will be liable to suffer serious injury. All plants that were left in the seed bed have been pricked off on a south border, so that if required they will be available to make good the failures.

Seakale.—Where it is intended to force this on the ground where the plants have grown, it will be necessary to put Seakale pots or cradles over the crowns and place a good body of fermenting material round about them. As but a mild heat is required, this should be composed principally of tree leaves, employing only just enough stable-manure to slightly supplement the warmth generated by the leaves. The covering must be sufficient to exclude light and air from the crowns. The chief thing to guard against is too much heat. A steady heat of from 45 degs. to 50 degs. is the most suitable, any increase of this being detrimental, as it causes the growth to be weak and flavourless. Hotbeds for

Forcing Potatoes recently placed in slight warmth to sprout are being made as fast as labour will permit. It is a mild and lasting heat that is required, therefore a good quantity of tree leaves is used in the construction of the beds. The manure and leaves are mixed together and turned over a few times previous to making up the beds. These are made 5 feet high at the back and 4 feet in the front to admit of their subsiding a couple of feet during the next two months. During this time the linings will be frequently made up to the top of the frames, both to keep out the cold and maintain the heat of the beds. The soil, which will consist of old potting soil with a liberal admixture of loam and leaf-mould, is put on to the hotbed to a depth of 9 inches as soon as the frames are placed upon it. The Potatoes will not be planted until the soil is thoroughly warmed through.

Lettuce plants in pits and frames require very careful attention at this season—excessive damp is the chief thing to guard against during the winter. Air should be given freely on all favourable occasions, and during mild weather a little air should be left on all night. Stir the surface-soil frequently, and do all that is possible to keep the plants healthy. These remarks also apply to all young vegetable plants being wintered in cold-frames.

Celery.—The earthing-up of the latest plants is now completed. Long litter has been placed in readiness to protect the plants in the event of severe frost.

Parsley.—There is at present a plentiful supply of Parsley from plants in the open. All decaying leaves should be removed to allow plenty of light and air to reach the plants, and some covering material should be at hand to protect them in severe frost or snow. Where Parsley is planted in frames, the lights should be kept off till as late in the season as possible to enable the plants to withstand a few degrees of frost.

F. W. GALLOP.

SCOTLAND.

Pot plants.—There are some things which must not be kept at this time of the year in a too cool temperature, even when intended to bloom at a later date. Among these may be mentioned *Libouia floribunda*, for if it does not receive sufficient heat it will rapidly lose its foliage. *Coleuses*, too, must be given a moderate allowance of heat, never falling under 60 degs., if it is intended to keep them in good form during the winter. Many growers of the *Coleus* rely upon seedlings; but when a good selection has been made, the plants are worth retaining, and the numbers can readily be increased from cuttings in the spring. Some things can be propagated at any season of the year if the needful conveniences are at hand. Among these is *Saintpaulia ionantha*, a very useful little plant for the stove or warm greenhouse. During the week a good batch of leaf-cuttings was got in. These readily root, and form neat little plants which will ultimately be bloomed in 4-inch pots. *Begonia Rex*, too, may be easily increased at this time in a similar way. The stock plants of *B. Rex*, too, appreciate a little extra warmth at this time.

Stove.—*Gesneras* still keep up a very good display. They, too, can be propagated to any extent from leaf-cuttings put in round about this time. Of course, they are quite easily raised from seed; but time and trouble are saved when leaf-cuttings are used. The *Begonia* family still maintains its popularity for winter blooming. *B. Gloire de Lorraine* and its varieties are indispensable. For a time, *B. Gloire de Sceaux* was looked upon with favour; but it is coarse when contrasted with other winter-flowering *Begonias*, and is not now so much used. *B. corallina* and *B. socotrana*, as well as the old *B. Weltoniensis* are, likewise, to a great extent superseded, although they are useful in their way. *Hymenocallis* have now finished their season of blooming. These fine plants must not after flowering be permitted to feel the lack of moisture. The young foliage succeeds the flower-spike, so that plenty of water is necessary, and I like to assist the plants during the development of the fresh leaves with a little weak stimulant. *Cypripedium* will continue in bloom for some time longer. The brightly-coloured bracts of *Poinsettias* are admirable; many object, however, to their somewhat scraggy appearance. This is accentuated when (as often happens) the foliage drops or is destroyed by red-spider. The latter may be checked by vaporising. Rather ungainly, too, is *Euphorbia jacquiniæ-flora*. I think the best way to grow this is to insert five or six cuttings in a 6-inch pot and to allow them all to grow and flower in the pot into which they were put. To a certain extent this does away with the appearance of straggling habit which mars this brilliant plant. I used to like *Bilbergias* and *Francisces*—especially *F. confertiflora*—for winter; but they have had to make way for plants of a more "all-round" character. *Gardenias* are always useful, but *Stephanotis* has in many places been given up, chiefly, I fancy, from the extreme difficulty experienced in keeping it free from mealy-bug and of cleaning it when that pest gets established upon it. *Bougainvilleas*—both *B. glabra* and *B. Sanderiana*—are always useful.

The greenhouse.—*Chrysanthemums* are, and will be yet awhile, the chief feature. One of the curious facts connected with *Chrysanthemums* during the present season is the forwardness of the reputedly late-flowering varieties. For example, that fine old white Sou-

venir d'une Petite Amie, when grown in bush form, has usually been at its best after the New Year. It has, however, come along very rapidly, and was in bloom at the end of November, or more than a month earlier than usual. Similarly, the old yellow *W. H. Lincoln*—still one of the best for late work in a general way—has anticipated its time of blooming. To prolong the display, careful ventilation and a fair heat in the pipes are necessary. Damp is much more to be dreaded in the case of *Chrysanthemums* than a low temperature.

Chrysanthemum cuttings.—These are being freely produced, and, albeit earlier than is liked, they are being put in. Clean pots are essential, and a light sandy mixture passed through a sieve of $\frac{1}{2}$ -inch mesh gives good results. About $\frac{1}{4}$ inch of sand on the surface of each pot is advisable. A proportion of this falls into the hole made by the dibber and forms a suitable bed for the base of the cutting. Single cuttings in 3-inch pots are recommended should the plants be required for large or exhibition blooms, but for decoration quite good results can be obtained by putting the cuttings thickly into 5-inch pots. These, if potted before the roots get interlaced, do not seem to be at all affected by the disturbance. I have grown quite as good plants—bushes, that is—in this way as from the more orthodox single cutting in a 3-inch pot. Some insist that *Chrysanthemum* cuttings ought to be kept air-tight until roots are formed. It is merely a matter of opinion. In my own case the cutting pots are placed upon a stage covered with crushed grauite, in a moderately warm house, and the results are invariably quite gratifying. By moderately warm is meant a house in which the temperature at night never ranges beyond 55 degs.; in frosty weather a few degrees less. Water, of course, is but sparingly given until roots are emitted.

Hardy plants.—The further removal or division of these will now be delayed until February. Meantime, it is advisable to mark such plants as it is intended to divide or to move to a different place. Cutting over is being continued as time can be spared. No doubt, neatly-cut-over plants are desirable, but if a trifle unsightly, the stems may be of value in protecting the crowns of certain varieties from severe frosts. Reputedly tender subjects may be protected. Here there is seldom any real need to do so. Ashes, well weathered, are as satisfactory a substance as anything else. Let care be taken during the progress of cutting over that labels are not displaced or removed. Stakes should be sized, tied up, and stored as the work goes on.

Roots in store ought from time to time to be looked over. This precaution is doubly necessary during the present season, when Potatoes did not lift over and above well. Any decayed or decaying tubers will very quickly contaminate sound ones, so these should be periodically removed. It is not so needful to overhaul such things as Beet or Parsnips, yet it pays to give them a look through occasionally.

Hardy fruit on walls.—A few degrees of frost are now bringing down the foliage, and it will shortly be possible to make a start with the delayed work of pruning and training in the case of Apples and Pears. Unfortunately, the frost has not been sufficiently severe to dislodge the leaves of Plums, Peaches, and Nectarines. There is no doubt that a certain amount of growth is yet going on in the case of the two latter fruits. This is to be regretted, for it means that the period of rest will be curtailed, which will very probably react on the trees next season.

Outside work.—Time has been devoted to raking leaves and tidying up, work which it had been intended to reduce considerably, but which has, after all, been completed.

W. MCGUFFOG.

Balmac Gardens, Kirkcudbright.

"The English Flower Garden and Home Grounds."—New Edition, 12th, revised, with descriptions of all the best plants, trees, and shrubs, their culture and arrangement, illustrated on wood. Cloth, medium 8vo, 15s.; post free, 15s. 6d. Of all Booksellers or from the office of GARDENING ILLUSTRATED, 63, Lincoln's Inn Fields, London, W.C.

CORRESPONDENCE.

Questions.—*Queries and answers are inserted in GARDENING free of charge if correspondents follow these rules: All communications should be clearly written on one side of the paper only, and addressed to the EDITOR of GARDENING, 63, Lincoln's Inn Fields, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent each should be on a separate piece of paper, the name and address being added to each. As GARDENING has to be sent to press some days in advance of date, queries cannot always be replied to in the issue immediately following their receipt. We do not reply to queries by post.*

Naming plants.—*All who wish their plants to be rightly named should send fair examples of each—the stem, leaf, flower, or fruit. (Snippets of leaves and points of shoots are useless.) Not more than four plants should be sent in any one week by the same correspondent. Where more than one kind is sent they should be numbered. Of course the fruit should always be sent.*

Naming fruit.—*Several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruits for naming, these in many cases being unripe and otherwise poor. We can undertake to name only four varieties at a time.*

PLANTS AND FLOWERS.

Delphinium Belladonna (R.)—In this the individual flowers are large and of a lovely azure blue, producing in the case of well-developed specimens a most pleasing effect and affording a charming contrast to the deep rich shades of colour which distinguish so many varieties of this noble summer-flowering perennial. *Belladonna* may be termed a dwarf-growing kind, as it seldom attains a height of 3 feet. It also is valuable in that it flowers continuously throughout the summer, thus rendering it a desirable and useful subject for massing.

Primula floribunda (J. F.)—This is a very accommodating plant, and of easy growth. In a cold-house, where there is a fairly dry atmosphere, it blooms profusely nearly all the year round. Shift your plants from thumb-pots into large 60's, giving ample drainage and sandy soil. Do not pot deep, occasionally pick off decayed flower-stems, and look after mildew or damp, the chief trouble to all winter-blooming Primulas. As the plants increase in size you can shift them into 48 sized pots. If then also you cut off all the winter stems a fresh lot of flowers in the spring will spring up and be very useful.

Rust on Carnations (Salopian)—Your Carnations have been attacked by rust, which is due to cold and generally uncongenial surroundings. The fungus vegetates within the cuticle of the leaf, and, attaining maturity, bursts the membrane of the leaf and distributes its particles of brown dust in all directions. Seeing you have only a few plants affected, we should advise you to burn all these. The others you might spray with a sulphur solution, using soft water, first reducing the sulphur to a mustard-paste consistency. One ounce of liver of sulphur (sulphide of potassium) dissolved in a quart of water, then added to 2½ gallons of cold water and syringed on to the plants has been recommended as a cure. Bordeaux mixture has also been recommended.

FRUIT.

Planting Peach-trees (H. L.)—While it is best to plant Peach-trees in the autumn or early winter, they may be planted up to February. Early planting means early rooting, hence the trees are more capable of withstanding the demand made upon them in the matter of leaf and wood production than when planted late. As to county, Peach culture under glass may be carried on safely anywhere, especially where the soil is naturally of a fairly firm loam, which Peaches like. If to such a soil, first deeply broken up, be added

wood-ashes, old mortar-refuse, finely crushed bones, and nothing else, the very best results should follow. Coarse manures should always be avoided, as these help to generate coarse wood growth that is undesirable.

Crops under fruit-trees (M. P.)—The best of all crops to grow under fruit-trees, provided the tree heads are not too dense, are Gooseberries, Currants, Raspberries, and Strawberries. A great deal, however, depends on the nature of your overhead trees, because, if the heads be close together, shutting out light and air, really nothing of any value will grow, and you must be content with one crop. If, however, the trees be fairly wide apart, and the heads kept thinned to admit plenty of light and air to the ground below, then you cannot do better than plant the fruits we have named. Generally all these do very well with some shade, but they should not be planted too thickly, or too near the trees.

VEGETABLES.

Diseased Potatoes (L. R. T.)—Your Potatoes have been attacked by the common Potato disease. The best remedy is spraying with Bordeaux mixture, which should always be done as a preventive measure, commencing about the first or second week in July or a little earlier in forward seasons. Three sprayings are an advantage, but one often protects to a large extent. Gather up all the diseased tubers and the haulm, and burn them, so as to check further inroads of the fungus.

Forcing French Beans (A.)—The seeds should be sown in 6-inch pots, several seeds in a pot, which should be about three-quarters filled with soil. A good variety for the early winter is *Syon House*, a good one for late winter being *Ne Plus Ultra*. These may be grown in the same house with Cucumbers, but they must be near the glass. It would be useless to attempt to grow them in such large pots as you mention. A stage erected in the house to keep the plants near the light is best for the purpose. You should, having once made a sowing, continue to make others for a succession every fortnight.

Parsnips (Amateur)—We fear your Parsnips are suffering in appearance and quality because grown in such rich soil. It is a grave mistake to grow these roots so large, as the flesh is very soft and watery, and the roots usually have a hard, woody core that is uneatable. When Parsnips are so soft fleshed they often become subject to an attack of fungus, which eats into the flesh and causes the formation of dark spots about the shoulders. Roots from seed sown at the end of April, that make fairly quick growth, yet do not grow large or run deep, make the best edible material, especially when properly cooked. The soil should never be fresh-manured, but have been so for a previous crop. An occasional dressing of soot does great good.

Forked Carrots (Mrs. Alfred Hartley)—The forking of Carrots is, as a rule, due to the addition of fresh manure to the soil in which they are grown, but as you say your Carrots were grown "after a crop of Potatoes and without manure," the cause of the forked roots must be due to something else. We take it from what you say that the ground was manured for the Potatoes, and this ought to have suited the Carrots. You tell us nothing of the depth of the soil. To grow Carrots two things are most important—the non-addition of fresh manure to the soil in which the Carrots are to be grown and seeing to it that the ground has been deeply dug or trenched so as to allow the roots to go down freely. In your case we should say that the ground was not properly prepared previous to sowing the Carrots. A heavy or clayey soil is quite unsuitable. Such a soil requires the addition of some material to lighten it. Carrots like a sandy loam of good depth. The same care is necessary in the case of Parsnips, Beet, etc.

MISCELLANEOUS.

Fowl-manure (W. W.)—In a fresh state this is of a heating nature. If allowed to become dry before using and stored until needed, it is of great value. A dressing of 40 lb. to the square rod when dry means about a bushel. But whether you have it green or dry get it spread over such ground as you wish to manure at once, and let it be exposed to the

weather for a few weeks, digging it in some time before the ground is sown or planted. Really, it is then good for any crop. Vary the dressing from year to year, so that the ground dressed with fowl-manure this winter will get straw-manure the next. It is a good plan to mix fresh fowl-manure with double its bulk of soil, and let it lie in a heap till the winter.

Liming soil (E. M.)—Lime is, as a rule, less needed for light sandy soils than for close stiff ones. Still, an application of fine-slacked lime at this time of the year is helpful, as any astringent properties in the lime are eliminated before cropping begins. You will find that the best way to apply it on uncropped ground is to put it down, unslacked, in small heaps of half-a-bushel per rod, then throw soil over it, and very soon it will become slacked. Then, with the soil mixed with it, spread it evenly over the ground. If your soil be rich in humus or manures, you will not need to give any additional manure for Potatoes; but if it be poor it will be needful to add some half-decayed manure to help give a crop. Add that some time after forking in the lime.

SHORT REPLIES.

Robeston.—Bamboo Co., 164, Lever-street, City-road, E.C.—**C. Bateman.**—Unfortunately, the shoot of Black Currant you send has been attacked by the mite, but before destroying the trees we should go over the bushes and remove all the affected buds. This may probably check the attack. See also reply to "A. T.," in our issue of December 9th, page 641.

NAMES OF PLANTS AND FRUITS.

Names of plants.—**Rob Roy.**—1, *Ceanothus azureus pallidus*; 2, *Cotoneaster frigida*; 3, *Pleasant* in flower; 4, *Escallonia* sp.; 5, *Azara microphylla*. When sending plants for name, kindly read our rules as to the number we undertake to name in any one issue.

Names of fruits.—**E. K.**—Apples: 1, *Wellington*; 2, *Golden Noble*; 3, *Lane's Prince Albert*; 4, *Bramley's*.—**M. K.**—Pears: 1, *Marie Louise*; 2, *Catillac* (stewing). Apples: 3, *Rymer*; 4, *Winter Hawthornden*.—**K. L. M.**—Apples: 1, *Norfolk Beaufin*; 2, *Lady Henniker*; 3, *Sturmer*; 4, *Winter Greening* (syn. *French Crab*).—**C. R.**—Apples: 1, *Alfriston*; 2, *King of the Pippins*; 3, *Cox's Orange*; 4, *Golden Noble*.—**A. S.**—Apples: 1, *Crimson Queening*; 2, *Ribston*; 3, *Scarlet Nonpareil*. Pear: 4, *Beurré Diel*.

Royal Horticultural Society.—The Royal Horticultural Hall having been offered by the Council to the War Office for military purposes, and having been accepted for the use of the Australian Imperial Force, the Government, recognising the national importance of the work being done by the Society, has been pleased to place at its disposal the Drill Hall of the London Scottish for such period as the Vincent Square premises remain at the disposal of the War Office. The Drill Hall is in Buckingham Gate, Victoria-street, opposite the Army and Navy Stores. It will be remembered that the meetings of the Society were held there for a long number of years before the Society built its premises in Vincent Square. There will be no further meetings and exhibitions of the Royal Horticultural Society in 1916. The first meeting, etc., in the New Year is fixed for Tuesday, January 16th, and it and subsequent meetings will be held in the Drill Hall. The Society's offices and library remain at Vincent Square as heretofore.—**W. WILKS, Secretary.**

NOTES OF THE WEEK.

Skimmia japonica.—This is now covered with its bright crimson berries, which are very bright when the sun shines on them. Being of slow growth, it is quite suited to the rock garden. It does not seem to be fastidious about soil, though a little peat or leaf-mould is appreciated, but the position should be in semi-shade.—C. T., *Highgate*.

Cupressus Lawsoniana Pottensi.—Those who like shrubs of columnar habit should make a note of this, one of the most elegant forms of the Lawson's Cypress we have seen. Of the gracilis type, it may be likened to *C. L. erecta viridis* in form, much more refined and elegantly clothed, and with a density and softness to the touch which separates it from all else. Endowed with the hardiness and free growth of its tribe, and with a certain glaucous tone which renders it at once distinct, there is no doubt that we have here a good addition to a useful class. It was recently exhibited by Messrs. Fletcher Brothers, and gained an Award of Merit.—E. H. J.

The Altai Rose.—Allied to our native Burnet Rose (*Rosa spinosissima*) and accounted only a variety of that species, *R. spinosissima altaica* is often catalogued as *R. altaica*. It is a really handsome Rose, with large, single, creamy-white flowers, and one of the earliest to bloom, coming in considerably before the forms of the Burnet Rose. Even in 1916, not an early season, it flowered in May. It increases freely by suckers (too quickly, indeed, for some positions). It is of fairly rapid growth, although not rampant, and forms an erect bush which may be kept down if required. I have a plant which is some 9 feet high, but about 6 feet is its usual height.—SCORCH ROSE.

Landscape architects.—Referring to the so-called landscape gardeners, or architects, as some prefer to call themselves, there is now a veritable flood of these embryo landscape gardeners, female as well as male, being turned loose on suffering humanity. They are being turned out in such numbers that I wonder what must become of them all. I have noted that nearly all these youths, and their teachers, can talk on landscape designs, but that so far as practical gardening is concerned they know very little indeed. Yet these men are intruding themselves upon those who have forgotten more of horticulture than the newly-fledged landscape artists know, and in not a few cases are allowed to submit plans, make changes, and sug-

gest or even superintend plantings for which they are unfitted.—J. N. CRAIG in *Gardeners' Chronicle*, of America.

Primula florida.—This first flowered in this country last spring. It is to the Edinburgh Royal Botanic Gardens that the honour of first flowering it is due. I saw it in bloom there, and was quite enamoured with its beauty. It has rounded, prettily-toothed leaves with a longish stalk, and lying almost flat on the ground. From these rises a slender scape or stem, carrying several flowers in an umbel and on short stalks. The mealy calyx sets off the rather long-tubed flowers, which are of a fine purple-blue when they open, passing off to a lighter shade. It is doubtful if *Primula florida* will stand our winters, but it should make a good plant for pots in loam, leaf-soil, and a little sand. A collection of such new Primulas would be exquisite in a cold or cool house.—S. ARNOTT.

Campanula haylodgensis.—This Campanula was raised by the late Mr. Anderson-Henry, at Hay Lodge, Edinburgh, a number of years ago, and bears a close resemblance to that capital dwarf Bellflower called Profusion. It has yellowish foliage and a plentiful supply of light-blue flowers. It is understood to have been a hybrid between *Campanula garganica* and *C. carpatica*. Mr. Anderson-Henry was, I believe, not too careful in checking his crosses, but the characters of this hybrid would indicate the probability of this statement being correct. *C. haylodgensis* is an excellent plant for the rock garden or for stone edgings to herbaceous borders. I think it prefers a certain amount of shade, and it can be grown well in loam and leaf-soil, with a little sand and grit. Those who find it impossible to obtain *C. haylodgensis* may secure Profusion in its place, and may rest assured that either will please.—S. ARNOTT.

Cotoneaster frigida.—I quite agree with all that Mr. Jenkins says (page 616) in favour of this fine Rockspray. It seems strange that its merits are not more generally appreciated, for in early winter it is one of the most conspicuous and beautiful objects in garden, pleasure-grounds, or shrubbery. It is grown here extensively in many positions, and never fails to attract attention. I have never seen it as a standard, but I can readily believe it will be additionally striking in such a form, for the growth is (in its younger stages) rather ungainly in bush form. Even so, it is by no means to be despised, and by judicious cutting a better shape can be formed. Some pieces in a shrubbery are at least 20 feet high, and are very

effective. Birds, unfortunately, have developed a liking for the fruit during the present season—a fact which may be accounted for to some extent by the scarcity of berries on other shrubs. In the winter of 1915-16 these continued to hang in good order till quite the end of January.—W. McGRUGG, *Balmae, Kirkcudbright*.

Aster grandiflorus.—The specific name here employed when this Starwort was first introduced, nearly 200 years ago, might have been applicable enough, though to-day, in face of all that has been done by modern raisers of these flowers, it is in the nature of a misnomer. Climax and a variety of the Italian Starworts are ahead of it to-day as large-flowered varieties go; head and shoulders above it as all know from the reliability, decorative, and utility points of view. How many, I wonder, have this year seen *Aster grandiflorus* at its best? Or, again, how often in a decade do we see this November-flowering sort at its best? These things notwithstanding, I would still direct the attention of the modern hybridist to it, since there are a size and colour of flower and habit withal to be desired, and these, used in conjunction with, say, some of the best Italian Starworts, might give us improved early-flowering varieties of medium habit of growth and good colour of which we have not yet dared to dream.—E. H. JENKINS.

Erica gracilis.—The typical representative of this old favourite, known far and wide in market and trade circles as "autumn gracilis" is one of the most ornamental and popular of its race—second to none, indeed, unless it be *E. hyemalis*, which, in its flowering, is contemporary with it. Beautiful at any time when the flowers in their prime assume that rich purplish-red which appears to attract everybody, it is seen at its best, perhaps, under artificial light. Just now numbers of the plants are seen in the shops of florists everywhere, the elegant bushes of rather more than a foot high covered with countless blossoms of the colour indicated. As a bright and effective subject for the sitting-room at this season, it is one of the good things worth having, one, too, that will afford pleasure for many days to come. Like others of the Heath tribe having brightly-coloured flowers, the colour remains to some extent when the plant is beyond the gardener's skill, in this way giving a good return for its cost.—J. S.

Begonia Mrs. J. A. Petersen.—This, of American origin, was first seen here rather more than a year ago, when exhibited by Messrs. Stuart Low and Co.

This firm has also more recently exhibited it, though the best cultivated batch of it I have yet seen was from Woburn Place, Addlestone. Though it may be of hybrid origin or a sport, it is obviously of the Gloire de Lorraine set, so far as habit, size, and time of flowering are concerned. It differs from all others of that class, however, by reason of the intense rose-carmine colour of its flowers, though more particularly in the deep coppery-bronze of its leaves. In this latter respect it is unique among its fellows—as distinct as it is ornamental and desirable. There are the freedom and continuity of flowering so typical of the original, and, like it, blooming freely even in the early stages of growth, it is likely to be serviceable from many points of view. In some of the plants there is a tendency to revert to the green state. That this is so is in some measure a confirmation that the new-comer originated as a sport, though I have no definite information on the point.—S. V. S.

Sedum spectabile atropurpureum.—One of the peculiarities of vegetable life is that of "sportiveness" so-called, that change from the normal or typical state which is responsible for increased variety, though not entirely of colour. This may be superior to the original, or the reverse, or both. In the case of this *Sedum*, after having remained normal for many years, the sportive tendency became evident a few years ago, and in diverse places at once, as sports not infrequently do. All are not alike in colour, however, and all are not of equal merit. Among the best of them is that named above, for which Mr. Amos Perry was given an Award of Merit years ago. Its nearest approach in colour that I have seen was in a broad belt where the plant was used as a margin to a shrub bed. So far as I remember, the variation was in the nature of a "root sport"—i.e., the whole of one plant was affected, and not a single branch only. Among the usual run of herbaceous plants such sports are uncommon. Both forms occur, however, in the *Chrysanthemum*, which, of course, is also "herbaceous." The object of this note, however, is to call attention to the richly-coloured form named above as among the most desirable of early autumn flowers. In a bed alone it is most effective. Contrary to general belief, too, the plant is obviously most at home in stiffish loam, and, so far as my experience goes, attains a greater colour beauty in such than in much lighter soils. In a cool, moist loam the stems of established plants approximate to 3 feet in length. Given such development, it is goodly to look upon. It may be planted now or in spring.—E. H. JENKINS.

Box-edging.—If I had ever so big a garden I should have very little Box-edging. It looks very nice when doing well and is properly cared for, but the pleasure it affords is too dearly bought. Planting is a tedious process, there is nothing in gardening that requires to be more carefully done, and the man who has to trim it annually could easily find a better job. In course of time it becomes gross, robs the soil, and if ever so tiny a bit of Couch or Bindweed gets into it it cannot be got out, and all the ants in the neighbourhood find it a happy home. Some years ago I made an edging to two flower borders, and for a couple of years it looked very well, and then lost colour. I took away the gravel and gave it a heavy dressing of lime, which made a great improvement, but when it got bigger I lifted it, and instead of replanting I collected all the big stones I could find in the surrounding fields and made the edging of them, and they are there now. Box is all very well when small, but when it comes to a

certain size it robs the ground of moisture and nourishment, whereas stones, in a measure, protect the roots, and one can plant close to them—a great advantage in the case of very dwarf things either tender or hardy. The more irregular in form the stones are the better I think they look—much better, I consider, than the edging tiles in use nowadays, and which I do not admire. Box edging is troublesome to lay and expensive to keep in order; stones are easily put in place, and when the border has to be renovated can be lifted and put back again in a comparatively short time. Some of our walks are edged with bricks buried to half their depth, and with a couple of inches of ashes one gets a nice comfortable path through the winter. New bricks quickly become dull-coloured.—J. CORNHILL.

FRUIT.

APPLE ALLINGTON PIPPIN.

The choice of Apples is a matter of great importance, and one that should not lightly be undertaken. It is quite likely that "W." has known D'Arcy Spice for a greater number of years than myself, but I also can claim to have known Allington Pippin longer than he! "W." places flavour as the first duty of an Apple, and I place good cropping qualities before this. Now, it is quite obvious that in selecting fruits from a varied collection in a fruit-room, everyone will place flavour first; but it is quite a different matter when a general recommendation is given of the "best" Apples, without qualification as to locality or soil. Regular cropping is then of the first importance. An Apple a few degrees below the best in flavour which crops well and thrives on a large range of soils will be more valuable than the most delicious Apple which is irregular in crop and fastidious as to soil. "W." says D'Arcy does well in Essex. Precisely, but where else? I have never seen it thriving out of that county, nor have I yet found anyone else who could speak well of it away from its native bounds.

Mr. Farmer thinks Allington is only liked by those benighted folk who have never tasted anything better. In the selections of Apples to which I referred in which it was placed among the first half-dozen, the voters were experienced gardeners, who know and grow all the main sorts of dessert Apples. Really, it seems time to protest against the setting up of personal tastes as a standard for all men. Many people like an acid Apple, and among my friends who share this preference I do not note any alarming symptoms of degeneracy or disease as compared with those who prefer sweeter fruits. I have never yet met the Apples which are "like vinegar" and require an "equal weight" of sugar to render them edible, and should much like to add such a fruit to my collection of pomological curiosities. It is quite easy to run down "market fruits," but it must be remembered that they fulfil two very important functions—they are, firstly, varieties which pay to grow, and, secondly, varieties which the public likes. Regardless of Burke's dictum, Mr. Farmer sets out to indict a nation. If the market-grower can be shown fruits which crop as well and will be more popular with his purchasers he will not be long before he supplies the demand. Mr. Farmer's remarks as to "manufactured" sugar, I fail to understand. How, where, and from what is sugar "manufactured." An answer to this question should be of value in these days of advancing prices.

In estimating the value of any fruit, I always should place its merits in the following order—vigour, crop, flavour. Allington Pippin will score higher in the

first two points than any of "W.'s" best six, and it is for this reason that it has become in the short space of twenty years one of the leading dessert Apples for general use, and has, in my opinion, fully justified its introducer's opinion as an Apple of good flavour, free-bearing, and a wide range of adaptability.

E. A. BUNYARD.

[*Manufactured sugar all must know as distinct from the natural sugar found in a fruit or vegetable—quite different in its effect. It is made largely from Beetroot, and in that form said to be less wholesome than from the sugar-cane. Its use on sour Apples is frequent, and the result far from being so good as where an Apple finds its own natural sugar as the Blenheim does.—Ed.*]

—The remarks under this heading in your issue of the 16th inst. will, no doubt, have been read with considerable interest by your subscribers. There appears, however, to be some confusion as to the standard by which this Apple is judged. As a market Apple it appears to be a success, both on account of its high-cropping qualities and the fact that it sells well to the general public. With regard to the Allington Pippin, I think we shall find many amateurs will agree both with "W." and Mr. W. J. Farmer as to its quality, but there is a good market for it. With regard to the D'Arcy Apple, I do not think anyone would recommend this to market-growers, but to amateurs this Apple must appeal on account of its wonderful qualities; in fact, it is pretty well agreed that this is the finest English Apple known. I was very pleased to read Mr. W. J. Farmer's remarks with regard to many recent Apples so-called dessert, which are lacking in quality. Nevertheless, these have obtained Awards of Merit and First-class Certificates at the Royal Horticultural Society's shows. One wonders what is the standard by which they are judged. It would appear as if size and colour were the determining factors for the committee.

I think I am correct in stating that there is a growing feeling amongst amateur gardeners that there is room for a Pomological Society in Great Britain, which could be run on similar lines to the Société Pomologique in France. The Apple question wants seriously tackling by somebody—at present there seems to be a condition of chaos. Descriptions in catalogues are misleading to say the least of it, and owing probably to the numerous first-class certificates and awards which have been given in recent times to poor quality Apples, we have undoubtedly lost a good many good old standard sorts, as it does not pay the nurserymen to grow them because they are not prominently before the public, and consequently are not asked for. I believe that Mr. E. A. Bunyard has been for some time devoting himself to getting together all these old varieties which were considered first-class in bygone days, and which are so described in "Hogg's Manual" and other books.

Your paper appeals mainly to amateurs, and I think it would serve your readers better if the discussion could be confined to Apples suitable for the amateur gardeners, and not necessarily for the market. I venture to send with these remarks a list of the best varieties, most of which I have personal experience of. I do not claim that these are the only ones, or that they come before any particular varieties which others can name, but I do claim that these are all first-class Apples, and granted that they will grow in the particular soil and climate of any amateur's garden, I feel sure that they would produce general satisfaction. There is one other point in Mr. W. J. Farmer's letter which I should

like to refer to—that is, King's Acre Pippin. This is a most excellent Apple in February and March, and I can endorse fully his recommendation. With regard to its origin, I speak under correction, but I believe that it is not actually known what the exact cross was, and it is only assumed that Ribston was one of the parents—in other words, the Apple was found as a chance seedling.

SELECTION OF DESSERT APPLES FOR AMATEUR'S GARDEN.

Approximate order of ripening:—

1. August.
2. September—October.
3. October—November.
4. November—December.
5. December—January.
6. February—March.

they would no doubt impress him with some effects of shop sugar. Also a visit to a sugar factory would tell him of things not always pleasant. As to the D'Arcy Apple, Mr. Bunyard's idea that it will thrive in Essex and nowhere else is one that can be easily tested. Does the stock suit it? We have evidence in plenty that fruit-trees, like others, will not all thrive on the same stock. Some Pears, for example, will never thrive on the Quince; many do admirably. An Apple of the quality of the D'Arcy deserves to be tried on the best stocks to see how far this charge of want of vigour is justified or may be remedied. Praising an Apple because of its bearing is beside the question. Otherwise one might name the Cider Apple-trees, which break down with fruit most years. If it were a matter of fertility, one need not go beyond Bramley or Domino, or a score of others—not to name

carefully cut out any berries in which decay has set in. Keep the bottles filled with water to within an inch or so of their mouths. After the Grapes are taken away the Vines can be pruned, taking the precaution afterwards to dress the wounds with "knotting" to avoid the risk of bleeding. The Vines and structure can then be cleaned when opportunity occurs. —K. P.

NOTES AND REPLIES.

The D'Arcy Apple.—Mr. E. A. Bunyard, not knowing what "manufactured" sugar is, makes me wonder if my understanding is in its usual place. He is young and strong, and has no need for consultation with the learned men in Harley Street, or

the Worcester Pearmain, which the fool voter puts on the top of his list.—W.

Grape-room.—With so much damp and fog to contend with, late-keeping Grapes will be less troublesome off than on the Vines. Advantage should, therefore, be taken of a fine, dry morning to get the bunches cut and transferred to the Grape-room, where, if everything is in readiness, the bottling can be quickly done. As great a length of lateral as possible—i.e., between the rod and bunch—should be cut with each bunch, this being the portion to be inserted in the bottles. The portion above the bunches, if of inconvenient length, may be shortened. Care must be taken to see that the bottles are not so full of water that they run over when the stems or pieces of lateral are inserted, as the drier the atmosphere the better will the Grapes keep afterwards. When finished, exclude the light, and maintain an equable temperature of 55 degs. Examine the bunches closely every few days, and

of the plant we give to-day. The flowers are large, pure white, with crisped edges.

The Willow-leaved Magnolia (*Magnolia salicifolia*).—This is one of the newest and most distinct of the numerous Magnolias, and promises to become one of the most useful. A native of Japan, it was introduced to the British Isles ten years ago, and already good-sized examples are to be met with in several gardens. In Japan it forms a small tree 20 feet or so high. Here it will probably grow as tall. The glistening white flowers, each up to 4 inches in diameter and made up of six narrow petals, are borne freely in April, well in advance of the leaves. It should be planted in well-drained loamy soil containing peat or leaf-mould, and in such a position that protection will be afforded from cold winds in spring and shade from early morning sun will be provided, for after a frosty night the flowers

are less likely to suffer if thawing is gradual than if bright sun suddenly shines on the frozen blossoms. The flowers are rather like those of *M. stellata*, but are not semi-double as are the blooms in that species.—D.

Aucuba japonica.—The form of this which nurserymen and others call "vera" is among the most attractive of hardy shrubs at this time, when carrying its clusters of brilliant-scarlet fruits. Well-furnished bushes, 9 inches or a foot high, have often been exhibited, and few subjects are more serviceable on window-sills in town or suburban districts. Less well-known is *A. longifolia*, whose leaves are longer, narrower, and more tapering. In good fruit it is less frequently seen than the above. The oblong fruits are brilliant scarlet. Quite near to this last is *A. J. Fletcheri*, the dark green shining leaves somewhat broader. The fruits are also larger. In this, too, the young shoots and leaf-stalks are green, while quite dark in the other form.—E. H. J.

The Chinese Fringe-tree (*Chionanthus retusa*).—Although this is a small genus, it contains two very interesting and useful species—*C. retusa* and *C. virginica*, the former a Chinese shrub, and the latter a native of N. America. *C. retusa* forms a bush 8 feet to 12 feet high in this country, but it grows very much larger in China, sometimes, it is said, being as much as 40 feet high. It was introduced originally about the middle of last century, but was little grown until reintroduced thirty years later. The white flowers are borne in June and July in large, light inflorescences, terminating short shoots, the inflorescences resembling somewhat those of the Manna Ash. It requires a sunny position, and should be planted in well-drained, loamy soil.—D.

The Virginia Creepers—their waning popularity.—When in a young state the delicate tendrils of the Virginia Creepers are admired, and autumn sets the leaves aflame. We are loth to think that a day may come when we should regret their planting. It has to be said concerning these once very popular creepers that people are beginning to think, after all, other things less troublesome might have been planted. "Never again," I heard it remarked the other day, when long shoots were being extracted from inside a spout and from under tiles, and had caused an overflow of rain-water much to the detriment of the bedroom walls belonging to the owner.—TOWNSMAN.

A delusion—Mendelism.—Writing on the breeding of yellow-flowered Cattleys, Mr. Rolfe, in the *Orchid Review* for November, says that "Mendelism provides no means of controlling the elements that it has to work with. If it were able to eliminate undesirable qualities there would be something hopeful about it, and even if it could foretell exactly what would happen in any given experiment the knowledge would be useful and prevent many disappointments, but it can do neither the one nor the other. It tabulates the results of hybridisation, from which it assumes the existence of characters that are indestructible, and that can only be reshuffled according to the law of chance, and it proclaims the existence of laws that it is unable to define. Mendelism is, in short, a species of symbolism, representing nothing more concrete than its own supposedly indestructible units, which can be sub-divided and recombined according to circumstances, and which are as shifting as the sand on the sea-shore." This is precisely what experienced plant breeders say with respect to Mendelism. It does not help the breeder in mating for characters that have not already been obtained, and he must take the knowledge that comes from experience as his best guide. Then Mendelism may step in and account for his results, but that is only a kind of counting and sorting the chickens after the eggs have been hatched.

PLANTS AND FLOWERS.

FERNS.

BRITISH FERNS.

ALTHOUGH the species of British Ferns, which are popularly known and grown in thousands of gardens, may be numbered on the fingers, and, indeed, in the vast majority of cases, consist but of four or five kinds, viz., the Common Male Fern, the Lady Fern, the Broad Buckler Fern, the Shield Fern, and the Harts-tongue, there are really no less than forty-four species, representing fifteen genera, indigenous to the British Isles. A certain number of these, it is true, hardly lend themselves to general garden use as decorative plants, presumably owing to their small size and the difficulty of imitating those natural conditions under which they thrive in their native habitats. Thus the Sea Spleenwort (*Asplenium marinum*), which lines the caves and dots the cliffs with its bright green foliage on many of our rocky coasts, especially in the west, will not stand inland outdoor culture. Deprived of salt-laden air it languishes, and despite its tough, leathery foliage, a very few degrees of frost suffice to kill it. It is, in point of fact, better adapted to sub-tropical conditions, and when grown in a warm greenhouse assumes a size and luxuriance of growth such as it never attains here under natural conditions, the fronds reaching a height of 2 feet and the plant forming a stout bush as much through. The delicate Maidenhair Fern (*Adiantum capillus Veneris*) is also a coastal Fern, but of more limited extension; this, too, is tender, and is confined to our warm western counties. A few of the other Spleenworts (*Asplenium*), *A. fontanum*, *A. septentrionale*, *A. germanicum*, and *A. viride*, may, under very favourable conditions of climate, be induced to survive in rocky chinks and crevices, but cannot be recommended as popular plants. The Adder's Tongue (*Ophioglossum vulgatum*) and the Moonwort (*Botrychium Lunaria*) belong to the same category requiring special conditions, while in no way appealing to taste as regards their beauty.

Outside these exceptions, however, there are many of the remaining species which are popularly ignored, but which are well worthy of a place in those rockeries which are devoted to the hardy Ferns already cited. The Buckler Fern or *Lastrea* group, for instance, popularly represented by the Male Fern (*Lastrea filix-mas*), and the Broad Buckler Fern (*L. dilatata*) embraces two other species of quite equal or greater merit, viz., the Lemon-scented Fern (*L. montana* or *Oreopteris*), and the Hay-scented Fern (*L. amula*). The former is an erect-growing Fern, with pale green fronds arranged shuttlecock fashion around a central caudex. These fronds are covered with glands, and when gently drawn through the hands an agreeable Lemon-like odour is perceived, whence its name. In habit and make it somewhat resembles the Male Fern, but is distinguished by the side divisions continuing right down to the base, where they taper into rounded lobes, while the Male Fern has a naked stalk of several inches, the side divisions then commencing are fairly long ones. *L. amula* is a little on the lines of the Broad Buckler Fern, but smaller, and with its fronds beautifully crisped and crinkled rendering it far prettier. *L. Thelypteris*, the Marsh Fern, resembles an attenuated *L. montana*, but has a creeping root, and only thrives in bogs. It is not to be recommended for garden culture. The

SHIELD FERNS consist of three members, viz., the Holly Fern (*Polystichum Lonchitis*), the Soft Shield Fern (*P. angulare*), and the Hard Shield Fern (*P. aculeatum*). The first is a true mountain Fern, rarely found below 2,000 feet. Its hard, lucent, green fronds are once divided, the midrib bearing two rows of acutely-pointed divisions, somewhat like Holly leaves, whence its name. Given a northern aspect, with its crown well sheltered by an overhanging rock or Brier, it will grow in the garden, but is rather apt to perish, unless the air be very pure. *P. angulare*, the Soft Shield Fern, grows much larger and has long, lax fronds twice divided, the segments resembling those of the Holly Fern in shape, but being much softer in texture, whence the name. The Hard Shield Fern (*P. aculeatum*) is stiffer in growth and tougher in make, but otherwise not very dissimilar. The

POLYPODY FAMILY, represented by the Common Polypody (*Polypodium vulgare*), the Oak Fern (*P. Dryopteris*), the Beech Fern (*P. Phegopteris*), and the Limestone Polypody (*P. calcareum*), are all available for rockeries in sheltered situations. The first-named is a very common Fern in many parts of the country, topping old walls and fringing the hedgerows and stone dykes with its pendulous, once-divided fronds. All four species have rambling, creeping root-stocks, but those of *P. vulgare* are thick and fleshy, those of the others are very slender and stringy, in a sort of mat whence the fronds spring, forming a dense clump. *P. vulgare* is quite evergreen, while the others die down in the autumn. As a result of this habit of growth a loose, open, leafy soil is essential. The

BLADDER FERN (*Cystopteris*) is not to be recommended for general culture, not being particularly beautiful, while the fronds have a habit of becoming brown very early in the season. Recurring to the Spleenworts, of which we have mentioned a few of the ineligible, the Maidenhair Spleenwort (*A. Trichomanes*) is a pretty little rosette-forming Fern which does well in chinks of rocks, and the Black Maidenhair Spleenwort (*A. Adiantum nigrum*) of very different habit, with upright, twice-divided fronds, is also a rock lover and forms a pretty relief among the robuster growers. The other Spleenworts (*Ceterach officinarum*) may do well in the chinks of a wall with sunny aspect. The Royal Fern (*Osmunda regalis*) is extremely handsome when well grown, but it is a moisture-loving species requiring plenty of water, and is most at home when its roots are in boggy soil. To plant it high up on rockwork is, therefore, to court failure. The Hard Fern (*Blechnum Spicant*) merits far more attention than it gets. It is a very pretty Fern, with dark green-shining, once-divided fronds of two kinds, leafy, barren ones, which form a spreading rosette, and thinner, erect, fertile ones, consisting of little more than midribs bearing the spores. It is quite evergreen and thrives in good leafy soil, provided it does not suffer from drought. The Parsley Fern (*Allosorus crispus*) is a pretty small-growing species, usually supposed to be difficult of culture, but really of the easiest if properly planted. Its normal habitat is on the sloping débris of mountain sides, where it is constantly liable to be buried by slips and slides of the loose material. The way to plant it, therefore, is to dig a hole with a northern aspect, half fill it with loose rubbly Fern-mould, lay the plant on that with the crown towards the north, and then bury it entirely with a shovelful of gravel; this done, drop a large cairn on the south side,

leaving room on the north for the new fronds to push through the gravel, as they will do. This done, leave it alone and it will thrive for years. The Lady Fern and the Harts-tongue practically remain to complete the list of available species, and both of these are too familiar to require description or cultural suggestion.

Given suitable positions and a little care these common forms are very pretty, but as we have seen it is only a few of these that are utilised, so that a popular British fernery is ordinarily, as we have said, a monotonous grouping of a few species only. What, then, will be thought when we assert that a fully representative collection of British Ferns would embrace many hundreds of distinct forms, very many of which far and away eclipse the common ones in delicacy and beauty? Yet that this is so is evidenced by the magnificent collection in Kew Gardens, where some thousands of British Ferns and some hundreds of distinct varieties exemplify that remarkable faculty which our native Ferns possess of spontaneously sporting into

the Buckler Ferns (six species), 259, and the Common Polypody seventy-five. A large number of these consists of beautifully-tasselled forms, others are delicately dissected and feathery, others are prettily dwarfed and congested, and others are varied on quaint and eccentric lines. There are, therefore, forms adapted to meet all tastes, all are hardy save these species already mentioned, and in short, given sheltered conditions from hot sun and destructive wind, there is no family of truly British plants which remotely approaches that of the Ferns in varietal interest and amenability to culture.—CHAS. T. DRURY, in the *British Fern Gazette*.

INDOOR PLANTS.

THE CULTURE OF THE VIOLET.

The cultivation of the Violet fascinates as much as the bloom itself. Although for years past Violets have been grown for the market, it has only been of recent years that the industry has taken a really serious

grower rents the holding, from £400 to £500 of capital would not be too much, although many have started with a smaller sum, and have been very successful. But with a nest-egg of from four to five hundred the novice should win through without having 'to cut and contrive' to any irksome extent." The

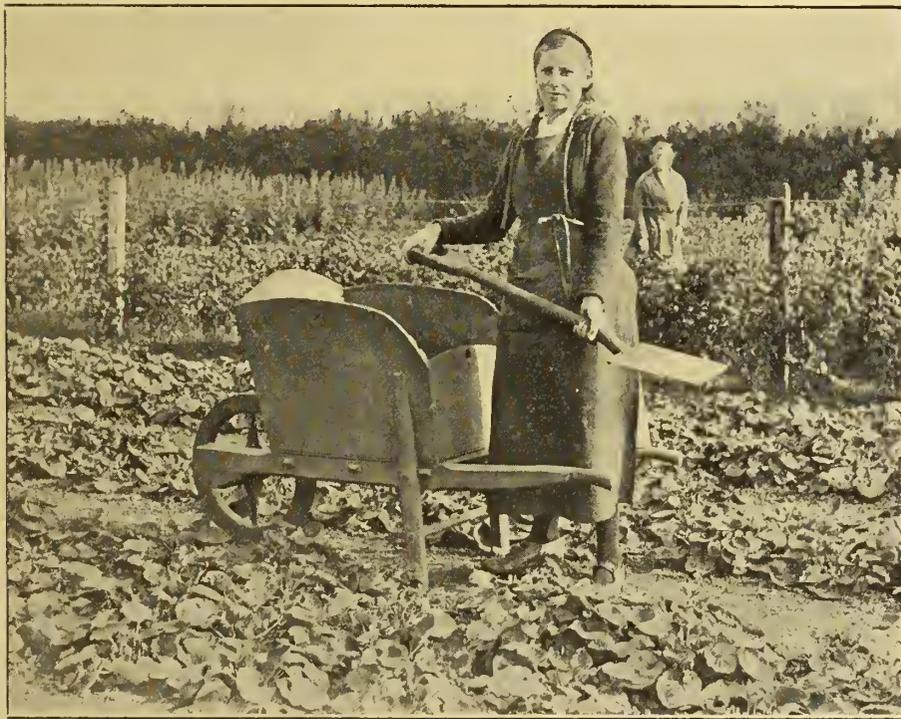

CHOICE OF A SUITABLE HOLDING is of vital importance. Violets will not flourish on either a too heavy or too light soil. They require a good medium soil. "The holding selected," Mrs. Coleman went on, "and the greenhouse or frames set up, next comes the choosing of the plants. There are many varieties, but I have yet to discover that one variety is better than another. I may say, however, that single are bought more readily than double Violets, although the latter have the sweetest scent. The single bloom, moreover, is the more profitable, in that it is much the larger and thus not so many Violets are required to make a bunch. Indeed, some growers produce a single Violet almost as large as a pansy, but in the production of this abnormal size practically all scent is sacrificed, and what is a Violet without scent?" The plants may be set in the greenhouse in the latter half of September, and if properly attended to will begin to bloom early in October, and continue to flower till April.

In this month, after suitable cuttings and runners have been taken from them for next season's use and planted in the garden, they may be thrown or given away. For each season young plants alone must be cultivated. Very little manure should be dug into the soil in the greenhouse, and in watering, great care must be taken not to pour any of the water on the plants themselves. Water from the tanks in the greenhouses must be used, as it is of the same temperature as the air in the building, hence its value. It is impossible to advise how often water should be given, this depending on the state of the weather. On mild, sunny days the soil beneath glass quickly becomes parched and the watering-can has to be used frequently, whilst on sunless, cloudy, moist days the soil remains damp and little watering is necessary. The plants must be carefully looked over from time to time, and all dead leaves pinched off, for, as with everything, one bad leaf, if allowed to remain, will invariably pollute the whole.

Eighteen double and from nine to a dozen single Violets to the bunch are the numbers required by the retailer, and with each bunch some foliage has to be given, and the whole should be bound together with bast, or in the case of those intended for private customers, fine wire or black thread. The retailer pays from 2s. to 3s. for a dozen bunches; private customers may be charged as much as sixpence a bunch when the flowers are scarce. In an average season a thousand Violet plants will yield about £25 worth of flowers. A point in favour of the Violet is that the plants require no extra heat, beyond that which the glass attracts, except when very severe frosts prevail. There is no such thing as forcing Violets. Begin to heat your houses artificially, and thus try to force the flowers, and most of the plants will rebel against the treatment, will cease to flower, and finally "damp off."

Mrs. Coleman does not depend on Violets alone for a living. Even in the winter she grows several other varieties of flowers. But Violets are her sheet anchor. She expressed the opinion that professional flower growing was an ideal occupation for the middle-class girl.

"It rarely yields a large income," she said, "but it does yield a comfortable living. What is more, all the work can be

Among the Violets.

types very different from the common ones. No man knows how or why it happens, but here and there among the normal species there is occasionally found a "sport," that is, a Fern of the same species as its neighbours and undoubted parents, but shaped and fashioned in quite different lines. Such a plant moreover, when removed and cultivated, not only retains its new form unaltered, but when propagated by its spores its progeny will be fairly true to the new type, or better still, may vary still more on like lines, so that greatly improved types are eventually obtained. Thus a Fern with once-divided fronds may sport into one with twice-divided fronds of much more feathery nature, and this may go on until in a few generations, or even it may be in one, we arrive at fronds so dense and so Moss-like in appearance, that only an expert could determine its species. Nearly every one of the British species has yielded "sports" of this description. According to the most recent descriptive catalogue the Harts-tongue boasts no less than 450 varieties, the Shield Ferns 384, the Lady Fern 313,

turn. The culture of Violets appeals strongly to the fair sex, because, unlike most other branches of outdoor work, it need not be pursued at the expense of dishevelled hair, heavy boots, and a general rough appearance. The Violet is not difficult to grow, and, provided you grow a sufficient number of plants, a living for from five to six months of the year can be had. A few days ago I met a very interesting woman, who has been a Violet grower for the greater part of her life. This was Mrs. Coleman, of Henfield, Sussex. She is a freeholder, owning a small house, about three-quarters of an acre of ground, and three greenhouses—two 100 feet in length and one slightly smaller. In speaking of the capital required to start a Violet farm of an acre in extent:—"It's the glass," said Mrs. Coleman, "that runs away with the money; and glass, either greenhouses or frames, but for preference the former, is the first essential. Without glass you can have Violets only in March and April, when they are plentiful, cheap, and unprofitable. "Presuming," she continued, "that the

done by the woman of average strength, except, perhaps, an occasional bit of heavy digging. As for Violets," she concluded, "they are the most profitable flower as far as I am concerned, and, strange to say, since the war I have sold more than ever."

J. C. BRISTOW-NOBLE.

Aldingbourne, Chichester, Sussex.

The Australian Fuchsia (*Correa cardinalis*).—When hard-wooded plants were extensively grown this was very generally met with. Like most of its class, it has, however, gone out of fashion. Though spring is given as its season of blooming, the flowers are often borne in the depth of winter, and are at this season much appreciated in the greenhouse. There are several species and garden varieties, but few of them can now be obtained from the ordinary trade sources. That under notice—*C. cardinalis*—forms a slender, spare-growing shrub, the drooping tubular flowers being bright scarlet tipped with green. Like all the members of the genus, it requires much the same treatment as the Cape Heaths—that is to say, it should be potted in a mixture of good peat and sand, taking care that the pots are clean and well drained. In potting, the soil should be rammed down very firmly. It is most essential that the ball of earth is not buried any deeper than it was before, as, if this precaution is not taken, the plant is very likely to fall into ill-health. Watering, too, must be carefully done at all seasons.—W. T.

GARDEN FOOD.

OATMEAL AND ITS RIGHT USE.

This is now in use from this year's crop. It is the best food grown in Britain, often misused by the ignorance of cooks, and served up in such a way as to resemble the paste of the bill-sticker. There are many people who have never tasted it in its right state. The other week I saw a lady at breakfast, who told me she could not bear even the sight of it. Of course, she had never seen the real thing. I get my Oatmeal from Scotland—usually in the form of groats from Annan, or pinhead meal from Dundee. Properly cooked and served it is the best food—quite unlike the pappy dish we see as porridge in English houses. Quaker Oats and other precooked cereals are good, but not quite so good as fresh, stone-ground Oatmeal. But you must have the best Oatmeal from Scotland or Ireland. Foolish people, in eating, put cream or sugar upon it. A little buttermilk or milk is far better. I prefer to eat it without milk or sugar, but with a little Clover honey scattered over it, a good way of eating Groats or Oatmeal after being well cooked.

Another important matter arises out of the use of this larger and cleaner form of the Oats, such as Groats. In using this, one gets away from the ground dust of the shop and has an article akin to Rice, in that it can be used for cooking like Rice. This also does away with the need of milk, to which many people object. Groats can also be separately cooked and served with vegetables, in the absence of meat, and in vegetable soups, thereby making a better-balanced dish.

The ways of eating this good food are worthy of notice. In England people seem not to have the least idea that they can eat it in some simple way with milk only, or buttermilk. A man I knew, who was very fond of it, used to put a quarter of an inch of manufactured sugar on the sloppy porridge and on top of that a bed of an inch of cream. Is it any wonder that he was gathered to his fathers before his day?

W. R.

YORKSHIRE PUDDINGS.

FARINACEOUS food can be counted on to supply four-fifths of the whole of the average diet. In spite of increased prices this form of food remains in most cases, comparatively speaking, the cheapest as well as the most economical form of nourishment. It supplies energy to the young, and this is essential to their welfare, for they require a good deal more of this kind of fare than do grown-up people.

Yorkshire pudding, Norfolk dumplings, suet puddings of various kinds, milk puddings, buns, scones, oat cakes, porridge, and other items that are easily made ought to be represented on the table at one meal every day. Yorkshire pudding is too often served as a heavy, greasy mass, when to be really appetising it ought to be light and most attractive in appearance. Old-fashioned English housewives know how to make this dish to perfection, and it is a pity that the recipe of days gone by seems to have been lost.

YORKSHIRE PUDDING.—The following recipe is good, and, if carefully followed, will result in a most satisfactory dish. Instead of allowing one egg to 1 oz. of flour in the usual way, 4 oz. of flour are counted to one egg. No more should be used unless baking powder is put in to lighten the dough. The batter should be kept fairly thick, $1\frac{1}{2}$ gill of milk to 4 oz. of flour and one egg being the right proportion. The batter should be allowed to rest before baking, and if baking powder is added it must be stirred into the mixture and well worked into it just before the batter is put into the oven to bake. The tin should be heated and lined with dripping, which is best done by placing it under the joint. When hot and sufficient dripping is in the pan, add the batter to about $\frac{3}{4}$ inch in thickness. Raise the tin very near the joint level with the fire, and turn the tin so as to give the heat to all parts of the pudding. When brown and done serve quickly. A Yorkshire pudding does not improve by keeping. If baked in an oven, the tin with dripping should be heated and placed over a covered fire. Then the batter is put in and allowed to start to bake before placing it in the oven, so that the pudding will bake equally in the centre and at the sides. This will not take place if the pudding is put directly into the oven. The sides will work up, driving all the fat to the centre, and preventing the pudding from rising, leaving it with a greasy, doughy centre.—*Daily Telegraph.*

FOOD VALUES.

WHEN Brillat-Savarin wrote "Animals feed, men eat, but only intelligent men know what to eat," he little thought how aptly his famous words would apply to the food question during the great war. It is the intelligent man or woman who has to think of the nature of the food that should be eaten to-day, not only in the matter of personal expenditure, but as a duty to the country. Meat is becoming scarcer and dearer, and it is necessary to seek substitutes—substitutes so well known in other countries. There are foods in France, in Italy, in Spain that are either ignored or under-estimated by the British public.

VALUE OF VEGETABLES.—It is to be regretted that the nutritive properties of Carrots, Turnips, Parsnips, Onions, Leeks, and Celery are not appreciated at their true value in this country, and it is not generally known that a combination of these vegetables, cooked for three or four hours, is a most nourishing food. In cases of serious illness a "bouillon de legume," or vegetable soup, is given in France to young and old; children thrive on it when they cannot digest anything else. For the normal person soups are made of these ingredients cut into small pieces, boiled in a saucepan full of salted water for three hours, with a tablespoonful of Barley per person added, and, before serving, a lump

of butter melted in the hot liquid. And of vegetable soups there is infinite variety. Sufficient is made at the time for two days' supply, which economises both labour and fuel. A French family will dine off a soup of this description, followed by a palatable dish of macaroni, Rice, or "pommes de terre au lard" (Potatoes cooked with cubes of bacon), a green salad or cooked fruit, and prefer this menu to a late meat meal.

AN EXCELLENT FOOD.—What does the general public know of macaroni in any form, whether spaghetti or macaroni proper? "An Italian compound—nothing in it," I have repeatedly heard it called. It is Italian assuredly, but how large a portion of the southern populations live almost exclusively on it is probably ignored. And how simple is the preparation of this excellent food! A pound of macaroni of a clean yellow colour broken in pieces and thrown into boiling salted water, cooked for twenty minutes, then strained and placed upon a hot dish with small pieces of butter and grated cheese—Cheddar, Cheshire, or Gruyere—inserted in the quivering mass deftly mixed with fork and spoon, is a dish for an epicure, and a hungry man. And with a good Tomato sauce as a variant, can a man or woman require anything more satisfying by way of a change from the heavy meat diet that brings so many ills in its train? Macaroni seasoned with a sauce of a stew, one of those juicy meat stews "in their own gravy" that the French know so well how to prepare, is another treatment for this "Italian compound." Do we recognise that there are other ways of preparing Rice than as milk pudding or boiled with curry? Rice treated like macaroni and flavoured with butter, cheese, and Tomato, or cooked in the water in which fowl has boiled, is not to be equalled. Here, again, do we realise how many people, Indian, Chinese, Japanese, live on rice alone? And we British, when we can so easily and cheaply obtain it, give it the insignificant place of a child's pudding!—F. KEYZER in *Daily Chronicle.*

NOTES AND REPLIES.

Value of Rice.—In view of the high price of Potatoes it is well to consider the comparative value of Rice as a food. Rice has over four times the heat and fat-forming principle compared with Potatoes, and its tissue-forming protein is some two and a half times greater, while its mineral salts are rather less than in Potatoes. The relative cost of Rice and its greater relative food value compared with Potatoes should be a matter of importance to the nation at this time. Rice well deserves to be far more freely used by the masses of our land and made to take the place of Potatoes at all times. As an article of diet it is easy of digestion and assimilation—much more so than Potatoes. It lends itself to various modes of preparation, savoury and sweet, readily blending with other nutritious articles of food; but plain boiled Rice should regularly take the place of Potatoes in our meals as a matter of real economy.—W. NARRAMORE in *Daily Mail.*

The Parsley-leaved Bramble.— "S. A. M. D." is right. I have tried the American Blackberries and found none nearly so good for our country as the above. It is a very free-bearing Bramble, handsome, useful, and I think a better thing than the Loganberry. Against a wire or other open fence it does well. I wonder, has Mr. Lynch, with his fine sorts of Blackberries, ever hunted out the best fruits in that good collection of our native Blackberries.—W.

OUTDOOR PLANTS.

A FLOWER BORDER ON A HAMPSHIRE HEATH.

We so long after rich loam and deep digging for our mixed borders that I was surprised to see how well one could do without all that on a sandy heath in Hampshire. The soil is a good, free, open sort, on which everything seems to do well, and the effect is excellent. The edgings are made of the very useful blocks of ironstone which are found on the heath. Good in shape and colour, they make the best edgings one could desire for fruit, flower, or kitchen gardens. For us stuck in

though one more free-flowering and of like size and colour would find a ready welcome.

PLANTING THE ADONIS.

Mr. Annett, page 637, speaks of "autumn as the best time for planting" these, and if the work is done fairly early—say, September-October—there is much to be said in its favour, so far as established plants are concerned. The Adonis has a root-system not widely removed from the Christmas Rose, in that both send down their main roots unbranched very deeply—2 feet or even much more—into the soil. In the ease of the Adonis, these main roots are produced over a more extended period

of heeling them into boxes containing weathered coal-ashes and Coconut-fibre in about equal parts, the warmer soil conditions so obtained being so congenial that even the smallest plants survived, rooting well into the mixture. Indeed, it answered so well that I subsequently employed it for many collected plants, Christmas Roses, hardy *Cypripediums* (save *C. spectabile*), the alpine *Anemone*, Pasque-flower, and others, which, coming to hand with the merest stumps of roots, had perished wholesale when put out into the soil even quite early in autumn, notwithstanding the soil was light, warm, and well drained. It may have been that sweating during transit had to some ex-

Flower border on a Hampshire Heath.

Kentish and Sussex Weald, how nice it would be to have one of these sandy Heaths near to draw upon to soften our asperities in our struggles with the soil.

W.

Violet Governor Herrick.—This new single-flowered sort, recently exhibited by Messrs. Blackmore and Langdon, appears, so far as size is concerned, to come into competition with *La France* and *Princess of Wales*, though distinct from either in colour—a rich reddish-purple, and rendered all the more conspicuous by a large white eye. Arranged with the two others named, the colour did not harmonise well, though alone it was distinct. In its way, it is difficult to conceive anything finer than *La France* as a winter-flowering sort,

than in the other plant named, hence the planting season may be extended also with impunity. I think it were better, however, to get the transplanting done early, and so give to the coming plant the maximum benefit to be derived therefrom. The main roots of both groups named— which belong to the *Ranunculus* order— have this in common—that once cut or broken they rarely, if ever, lengthen again, and frequently die back to the root-stock. Where this is so, recovery takes a longer time. Where the roots live, they presently send out fibres laterally, which tide the plants over a difficult period.

Years ago, when receiving big consignments of collected plants of *A. vernalis* chiefly, I found that autumn-planting was so fatal to them that I hit upon the plan

tent ensued, though this could not be wholly accountable for the loss. Indeed, there was this conflicting evidence—viz., while the largest of the batch perished when put into the ground, the smallest—the fragments quite unfit for sale—put into the ashes and fibre mixture for convenience at the moment invariably pulled through. One year I had an undue proportion of small fry—probably some two or three hundreds—and it was the discovery in spring that they were rooting through the boxes that afforded me a most valuable lesson. Planted and established, they were seen the following year by the late Robert Parker, of Tooting fame, who pronounced it "the finest bed of Adonis he had ever seen." The soil was light, very dry in summer, hence it was generously

treated with old cow-manure. How many hundreds of plants this accidentally-obtained lesson saved me in subsequent years I do not know. The broad facts are, however, recorded for what they are worth in the hope that those who have not experienced great success with a beautiful spring-flowering plant may be encouraged to further efforts.

Given the above treatment, I have not found division inadvisable, though I am at one with Mr. Arnott in his recommendation of increase by means of freshly ripened seed. E. H. JENKINS.

PIMPERNELS FOR THE GARDEN.

OUR NATIVE BOG PIMPERNEL (*Anagallis tenella*) is a gem for the bog garden and one of the most charming of the genus to which it belongs. It is not, however, one which can be accommodated in the ordinary garden, and those who have only beds and borders of common soil or a rock garden must grow some of the exotic species, which are best treated as annuals. In their own land they are generally perennial, but they cannot stand our winters without protection, and it is hardly worth while preserving them during winter in frames or greenhouses, seeing that they can be cheaply and easily grown from seeds sown in spring. These Pimpernels are best sown in the same manner as half-hardy annuals. They can also be sown outside at the end of April or in May. They must have a sunny position, so that their full effect may be obtained. With plenty of sun these beautiful little flowers will display themselves to advantage. Any common soil, not of a heavy character, is suitable. A pretty little trailing plant is

ANAGALLIS INDICA, known as the Indian Pimpernel, which is of trailing habit, and gives an abundance of small, bright-blue flowers. It is, however, eclipsed in public favour and in beauty by the Italian Pimpernel,

ANAGALLIS LINIFOLIA, more frequently called *A. Monelli*, a most variable plant in cultivation, so far as regards its colouring, varying from blue through purple, ruby, scarlet, rose, and lilac. It is of more erect habit than the others named, and produces an abundance of flowers on neat plants with narrow foliage, and from 9 inches to 12 inches in height. A variety called *Parksii* has bright red flowers, and one named *Phillipsii* has these of a deep blue. Mixed varieties are also obtainable, and are very beautiful in beds, in clumps, in borders, or in the rock garden. S. A.

GROWING THE KAFFIR LILY

(*SCHIZOSTYLIS COCCINEA*).

I FIRST saw this some fourteen or fifteen years ago in Messrs. Backhouse's nursery at York. The plants had a splendid bed of rich light loam on the north side of a fairly high hedge, and in this position the flowers always developed well until very late in the year. Again, I found the plant in Yorkshire, four years ago, in a garden high up above Ilkley, on the edge of the moors, and here again it was in a very shady position, and was flowering gloriously quite late in November. My own plants here at Stevenage are in a very shady place under an old Plum-tree. I put them there because they had not done so well as I expected in a sunny situation. In spite of frost and every sort of poisonous weather, I have been picking *Schizostylis* for the house and to give away until about a week ago. Then I lifted a few dozen half-developed spikes, together with a number of even more backward plants, and potted them up in a very large pan and brought them into a cool greenhouse. They have not resented the disturbance in the least, and already those spikes which were at a half-developed

standstill a week ago are opening brilliantly and well, and the pan gives promise of a succession which should last until Christmas or later. This, although it is answering well, is rather rough-and-ready treatment, and the better way to secure late flowering under glass would no doubt be to pot up strong roots earlier in the year, keep them back by standing or plunging the pots in a northern exposure until late in the autumn, and then bring them under glass to flower.—CLARENCE ELLIOTT, in *The Garden*.

MULLEINS FOR GARDEN AND WOODLAND.

SOME of the *Verbascums* are natives, but only three—the Moth Mullein (*V. Platytaria*), the Dark Mullein (*V. nigrum*) and *V. Thapsus*—are sufficiently beautiful to claim a place in our gardens. Of these three, *V. Thapsus* is perhaps the most striking, its branching spikes of yellow flowers forming a pleasing feature on hedge banks, by roadsides, and on other waste ground in the summer months. The

Verbascum phlomoides.

basal rosettes of leaves closely resemble those of the Foxglove, except that they are of rather more woolly texture, and on more than one occasion we have known the Mullein to be culled from the hedgerow and planted in the garden in mistake for the Foxglove. Mulleins usually occur wild where the soil is gravel, sand, or chalky. Most of the wild and cultivated Mulleins are of biennial duration and should be raised from seed sown in the open in early autumn or in frames in early spring. There are no difficulties attending cultivation, the chief aim being to get them into their permanent quarters as early as possible.

Far grander, from a garden point of view, are such species as *V. olympicum*, a giant of its race from Bithynia; *V. phlomoides*, the Woolly Mullein; the perennial *V. phœniceum*, with violet flowers; and the Nettle-leaved Mullein (*V. Chaixii*), all natives of Southern Europe. Most of the *Verbascums* are old-fashioned flowers that seem quite as much in place in a cottage garden as in the extensive grounds of a manor house. It is grand to see them massed with other old-world plants near

to the house, with Thyme, Thrift, and low-growing Bellflowers in the foreground. The cool, grey foliage and stately flowering spikes of *V. phlomoides* associate remarkably well with Campanulas, Evening Primroses, Foxgloves, Columbines, Hollyhocks, and Monkshood as border flowers. The smaller Mulleins are pleasing when seen growing on old stone walls; indeed, they are such handsome plants that they look well in almost any situation. We have seen them on old stone walls in company with Snapdragons, Corydalis, Dianthus, Geraniums of the dwarfier species, like cinereum, Endressi, and ibericum, the Violet Cress (*Ionopsidium acule*), a little annual less than 2 inches high, with pale violet flowers open at all times of the year, Wallflowers, and Arabis.

V. OLYMPICUM is one of the giant species of this genus. It grows to a height of anything up to 10 feet, sending up enormous candelabrum-like branching spikes of sulphur-coloured flowers well above its handsome silvery woolly foliage. It is almost invariably referred to as a biennial, though it will live for at least four years. *V. phœniceum* has violet or red flowers, and as most of the *Verbascums* hybridise very freely, this species is no doubt responsible for the remarkably rich colours seen in some of the newer hybrid *Verbascums*. From a packet of hybrid seeds the colours may embrace rose, rosy-buff, lilac, purple, crimson, crushed strawberry, and tones of coppery-red; and by judicious selection from these hybrids, pleasing and at the same time uncommon effects may be obtained.—*Country Life*.

UNSUITABLE PLANTS IN THE FLOWER GARDEN.

THE illustration of *Solanum jasminoides* on a Sussex house in a recent issue shows what the plant is capable of doing under such conditions, and is a sharp contrast to the specimens often seen in flower beds in the open air. In common with several other plants of a somewhat similar habit of growth and requiring about the same atmospheric conditions to grow it well, it has been used in large beds for summer work occasionally fairly satisfactorily, but often very much the reverse. Plants of a similar character I have in mind are *Plumbago capensis*, *Bougainvillea glabra*, and *Streptosolen* or *Browallia Jamesoni*, and of all it may be said that they look quite out of character, and certainly no plant lover can appreciate them when grown under such conditions. If large plants of a tender nature are required in the flower garden they can be found in things like the best of the *Marguerites*, *Salvia Glory of Zurich*, *Bouvardia corymbiflora*, also extra sized *Pelargoniums* (both Zonal and Ivy-leaved), and *Fuchsias*. It is to be hoped that when our gardens return to their normal character we shall see little more in our flower beds of those plants that are only at their best when allowed to develop at will their trailing or climbing habits, still less many other things that have been pulled and trained into shapes quite at variance with their true character. Many growers regard a certain number of tender plants as quite indispensable in the flower garden through the summer, but where they are used it is certainly advisable to have them as far as possible in their true character. With the wealth of *Roses* now at our disposal plenty of material is available to plant many beds, a favourite plan now being to utilise some good continuous-flowering variety in the Hybrid Tea, Perpetual, or dwarf Polyantha sections, and plant thinly on a carpet of some dwarf plant like *Nemesias*, *Petunias*, *Linaria*, or Tufted Pansies of the *Violetta* section. E. B. S.

Hardwick.

CHRYSANTHEMUMS.

NOTES AND REPLIES.

Ball-shaped Chrysanthemums.—I should feel much obliged if any of your readers would kindly give me the names of any Pompon Chrysanthemums that have ball-shaped flowers, not flat.—J. HANCE.

[The only true ball-shaped Pompon Chrysanthemum is the variety *Mdlle. Elise Dordan*, a beautiful pale silvery-pink flower of exquisite form. A few sorts that under good culture develop blooms that are almost circular or ball-shaped, as you express, are the following: *Kate Mannings*, sometimes given as *Katie Mannings*, a rosy-bronze sport from an old variety named *Model of Perfection*. The latter may still be obtained, and the colour is rose-lilac. This variety is synonymous with a variety named *Ada Vincent*. *Snow-drop* (white) and *Primrose League* (primrose) are two refined and beautiful sorts, rather smaller than most other Pompons, and extremely dainty when partially disbudded. A pink-tinted sport of the same family is named *Gertie Waterer*, which can even now be procured. Two very minute Pompons of circular form are *Baby* (deep yellow) and *White Baby*, both very tiny flowers. *Florence Carr* (deep bronze) is another little-known Pompon, which has flowers of rather ball-shaped form; and two of the oldest Pompons, *Mdlle. Marthé* (pure white) and *Golden Mdlle. Marthé* (a yellow sport from the last-named), are both excellent Pompons. However, they and most of the better Pompons must be disbudded to get round flowers of the kind you desire.]

Chrysanthemum La Triomphant.—Some varieties of Chrysanthemums are more addicted to sporting than others, and the above-named is one of them. Although an old variety, as Chrysanthemums go, *La Triomphant* is yet very useful for early flowers, and can be grown with but little trouble to produce large and massive blooms, or, what is more useful, as a bush plant which will provide plenty of material for cutting. The colour is of a pinkish shade, turning paler with age. Of late years a useful white sport has arisen. In addition we have now a yellow form of *La Triomphant*, all three, naturally, flowering simultaneously. As indicating the sportive character of the variety it may be said that plants in bloom here show variations in the flowers of individual plants, pieces of *La Triomphant*, the type, having pure white flowers, while there are similar changes in the case of white *La Triomphant*, which is carrying blooms both white and pink, while others have a mixture of both colours in the petals. All the forms have a tendency to mildew which seems to be inherent in the variety, but, curiously enough, it does not affect other Chrysanthemums in their neighbourhood, and is probably induced by a certain weakness of constitution.—W. MCG., *Balmac*.

Single Chrysanthemum Miss Rose.—This old variety still holds its own in the estimation of many growers. It lends itself admirably to bush cultivation, and some very fine specimen plants have been exhibited in past years. It is largely used for conservatory decoration, and is one of the most useful in the winter garden at *Tollerross, Glasgow*.—SCOTSMAN.

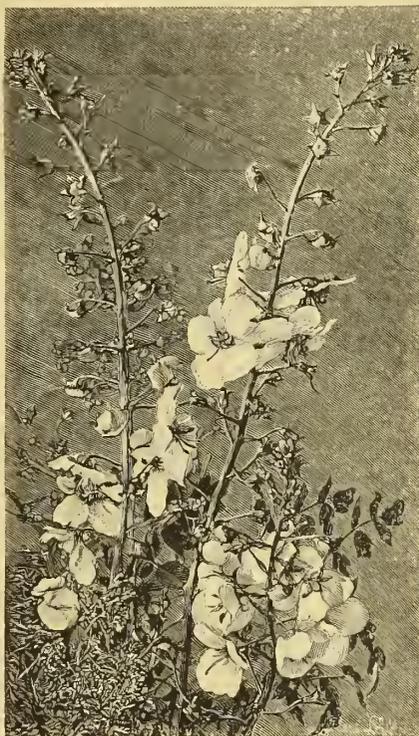

Single Chrysanthemum Miss A. Holden.—Those of us who remember the advent of such single Chrysanthemums as *Miss Mary Anderson*, and who have grown it for years, appreciate the variety called *Miss A. Holden*. It is a sport from *Miss Mary Anderson*, and has been in cultivation for some years. It is a counterpart of *Miss Mary Anderson*, but has flowers of a good yellow.—SCOTSMAN.

VEGETABLES.

POTATOES NEXT YEAR.

[To the Editor of GARDENING ILLUSTRATED.]

SIR.—I have read "Byfleet's" remarks on "Potatoes in 1916," in the issue of November 18th, page 576, and am sending you this letter on "Potatoes Next Year"

Verbascum phoeniceum. (See p. 672.)

because I think the subject is one of vast importance to all gardeners and farmers. Most of the gardeners of my acquaintance take little interest in the cultivation of the Potato. Up to the present there is "no halo of glory" attached to getting a record Potato crop; men are not encouraged to do their best, for Potato culture is, up to the present, considered a very dull job. "Just dig or plough up a plot of land, stick a few tubers in," and, except for moulding them up, the rest is left to Nature. The man who takes a real interest in the cultivation of the plant is scorned by his fellows, and gets none of the recognition he deserves for the good work he is doing. After two years of war we are beginning to realise how much the Potato is to us, and there are many who wish they had paid attention to the better growing of it. I spoke to an allotment holder a couple of days ago, and he told me that he had, without purchasing costly artificial fertilisers, got 56 lb. of tubers from a single pound of seed tubers. Of course, this record has been largely exceeded in some parts of the country. "Byfleet" says that "Yorkshire is a bright spot in a dismal record," but, as I live in this country, I may say that the prospects are none too rosy. We, too, have had short crops. On one piece of very rough land taken over to be worked along with my garden and planted very late with Potatoes, I only got eight times the weight of seed put in, which was poor in the extreme. Doubtless, I shall do better next year, for I shall have time to get the land ready. Owing to the wetness of the season, many Potatoes in the district produced masses of haulm at the expense of tubers. *King Edward VII.*, a variety in which I have great confidence, producing haulm between 4 feet and 5 feet

in length! Next year we shall have to cultivate as many Potatoes as we can because of their value as food. With good cultivation I believe it is possible to quadruple the crops we got this season. Gardeners and farmers cannot do all this alone. It must be made worth their while, for what is the good of doing one's utmost to get a huge crop of Potatoes if there is no market where they can be sold at over cost price? Farmers, however, will no doubt realise there is likely to be no lack of profitable markets next season judging by the present scarcity and great demand for Potatoes. As to inducing farmers and gardeners to do their best to grow the big crops one hears about, this must be the duty of the agricultural and horticultural societies, of which there are so many hundreds in this country at the present time. Prizes for the best crops of Potatoes ought to be a special feature.

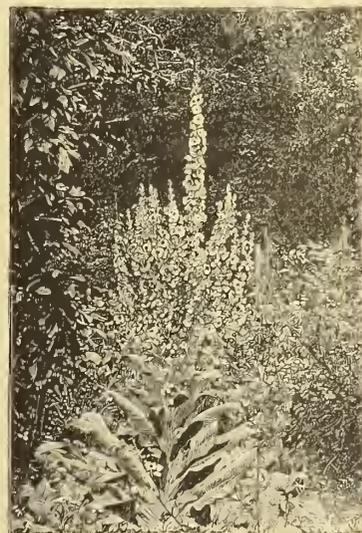

E. T. ELLIS.

Weetwood, Ecclesall, Sheffield.

GROWING MUSHROOMS.

(REPLY TO "F. R. S.")

THE proper way to prepare the manure is as follows:—It should be collected daily or as frequently as possible, and not allowed to remain in a heap, where it is liable to be much injured, or perhaps spoilt, in a very short time from overheating. It should be stored rather thinly in an open shed, and when sufficient is collected to form a bed it should be all thrown into a heap. Directly it is found to be very hot, and before the centre has heated dry, the heap should be turned inside out. This should be repeated three or four times, and in this manner the whole will be sweetened and yet be fairly moist. Thus prepared, the beds, when well rammed down, need not be more than 9 inches deep in front and 12 inches at the back; but with inferior or dry and partially exhausted manure, which some growers have unavoidably to deal with, increase the depth of the beds by at least another 3 inches. The aim should be to secure a good, lasting, but not violent heat, without which the crop will either be a failure

Verbascum olympicum. (See p. 672.)

or a very thin one. Where inferior or badly-prepared materials are used the heat of the bed is apt to decline to below 60 degs. before the mycelium has taken possession of the beds. Spawn the beds directly the heat has declined to about 80 degs. The longer the beds retain their heat, provided they do not become too dry, the better will be the crop and quality of

the Mushrooms. When the beds are formed before the manure has been properly prepared, or when it is prepared in the open and unavoidably becomes wet and cold, there is sure to be much steam generated directly fermentation commences, and in this case unless great care is taken the spawn may easily be spoilt.

SPAWNING AND SOILING the beds materially affect the value of the crop. Make shallow holes either with the hand or with a trowel, and use lumps of spawn about 2 inches square, disposing them about 5 inches apart each way. Soil the beds directly after spawning, and thus avoid any disturbance to the bed and the interruption of the spread of the spawn. It should be borne in mind that the spawn takes possession of the soil, and a good thickness of it, being less liable to become too dry, also ensures the production of larger Mushrooms. Much depends upon the nature of the soil used for surfacing the beds. Where possible, it should be procured from high and naturally-drained pasture-land, and be taken either from below the thinly-pared-off turf and used at once, or the turf itself may be cut and stacked for several mouths in common with the potting-soil. When used it should be broken up finely, be kept fairly dry, and placed in the Mushroom-house if very cold in order to warm it somewhat. Use a good thickness of it, or not less than 2 inches when beaten down, and never water the surface as it is beaten in order to make it run together.

NOTES AND REPLIES.

Soil covered with ashes.—I have a piece of land on which town ashes have been deposited 12 inches to 18 inches deep. The soil is very thin, on heavy clay subsoil. I am trenching this and mixing with the ashes after sifting. The old tins have mostly decayed, and the drainage water is red. Is this oxide detrimental or otherwise to plants.—**CRITIC.**

[Seeing that the soil has such a large quantity of ashes mixed with it, we are afraid you will fail to get anything to succeed, or but indifferently, unless you can counteract the harmful effect of the ashes by adding more soil of some description to the plot. If you have a good-sized heap of garden refuse in an advanced stage of decomposition you could, after freeing it of the rougher particles, employ this with good effect. The cleanings of ditches when undergoing their annual turning up could also be used with advantage, and the same with regard to the sidings of roads, provided the latter are not of the tarred macadam type. This kind of material can generally be had for the trouble of carting. You may also be able to find, on inquiry, that soil of a better or similar description can be had in your locality. Unless you can add to the plot in the manner indicated, so that it will contain soil in the proportion of at least three-fourths of the whole, we can hold out no hope of your being able to obtain any good results. The oxide would then do no harm.]

Autumn Broccoli.—Up to the time of writing, these have given a regular succession since the Cauliflower season closed. The now well-known Self-Protecting Broccoli has been an early winter treasure for some years past, and the pioneer, no doubt, of other good stocks of these early-maturing Broccolis. I have been cutting capital heads for some time from such sorts as Michaelmas White, Autumn Protecting, and Self-Protecting, successive sowings of which often maintain a supply until Christmas, or later. Winter Mammoth, First of All, and Early Penzance are others that give a good succession. I have not always been for-

tunate in getting a good stock of the Penzance Broccoli. Winter Mammoth I regard as indispensable. It is quite true this will not stand real wintry weather, but as one cannot forecast such events we cannot afford to neglect these early, though tender, Broccolis, as, should the weather be favourable, they yield one of the most desirable of our winter vegetables. It is only by frequent sowings one can keep up a succession of these several stocks, especially the early autumn and winter varieties, such as these named, which, given favourable weather and good cultivation, will give a supply extending over, at least, four months.—**W. S.**

Seaweed.—A note on this by "G. G. B.," at page 571, should interest those who live near the sea. I mix farmyard manure with Seaweed in equal proportions. If turned several times, the resulting mixture makes a fine and easily-handled compound, the value of which, especially for Brassicas during a dry summer, cannot be over-estimated. "G. G. B." will find, too, that it can be safely dug or ploughed in when fresh. One of the heaviest crops of Onions I ever saw was in the neighbouring shire of Wigtown. This crop was grown upon soil manured solely with freshly-gathered "wrack." The bulbs were large, not by any means show-bench specimens; but, as they were marketed in Glasgow in an undried state, a little coarseness was not objectionable—at any rate, the bulbs paid their grower—a small farmer—a very handsome return. The best Seaweeds for manure are *Fucus digitata* and *F. serrata*, in the order named, and a novice in a single lesson may be taught to distinguish between them.—**W. McGUIFFOG, Balmac, Kirkcudbright.**

The Carrot bed.—Carrots delight in a light, yet deep and friable, soil, whilst deep, retentive soil is generally looked upon as totally unfit. Even such a soil may be brought to a state as will grow good crops of Carrots. Too many, I fear, lose sight of that most important factor, not only in the cultivation of Carrots, but of other vegetables, viz., the winter preparation of the ground. We do not all possess land that is light and friable, as many of us have to do with stiff loam, bordering on clay, that, if not worked, becomes hard, and in a wet season sodden and unfitted for some crops. As Carrots are deep-rooting we must, in the winter, dig deeply, throwing the soil well up for frost to have a chance of lightening it, first incorporating with it road scrapings or any similar gritty material. The recommendation to sow Carrots on ground that has been well manured for a previous crop is practical, for it is well known that ground freshly manured is often the cause of "forking." The site for the bed should, therefore, be decided upon at once, and the work taken in hand, so that when it is time to sow, the soil will be in a light, mellow state.—**DERBY.**

Savoy Cabbage Sutton's Sugar Loaf.—I have grown this for the first time this year. It is claimed that the small types of Savoys possess the finest flavour, which may or may not be true, as the very best vegetables may be spoiled in the cooking. I believe that the larger-headed Savoys are objected to more from being badly cooked than from any lack of quality. Savoys when over-grown have bleached leaves that cannot be changed to green by the process of cooking, and it may be that that gives rise to complaints in the matter of flavour when compared to the smaller head that has a correspondingly greater proportion of outer green leaves. Certainly, the sallow leaf of an overgrown Savoy appeals neither to the eye nor the palate. This Sugar Loaf Savoy, if cut as soon as matured and well cooked, would afford no occasion for complaint.—**WILTS.**

THE WEEK'S WORK.

OPEN-AIR GARDENING.

IN BLOOM DECEMBER 18TH.—*Correa magnifica* (slightly protected from frost), *Escallonia montevidensis*, *Laurustinus*, *Jasminum nudiflorum*, *Daphne Mezereum*, *Andromeda floribunda*, *Osmanthus ilicifolius*, *Veronicas*, *Christmas Roses* (*Helleborus niger*), *Erica mediterranea hybrida*, *Erica carnea*, *Sternbergia lutea*, *Iris stylosa*.

THE WEEK'S WORK.—Work continues to be chiefly of a routine nature. The rock garden needs frequent attention, as leaves collect in nooks and crannies where their presence may soon destroy some tiny gem which withstands the severest of frosts or heavy falls of snow, but which resents a covering of decayed vegetation. After hard frosts, too, some shallow rooting subjects may be found partially raised from their bed. These require to be carefully replaced and made firm before another spell of frost is experienced. Plants like *Androsace Chumbyi*, *A. lanuginosa*, *A. sarmentosa*, and many others now require the protection of a piece of glass fastened in such a way as to allow the plants to have plenty of light and air, but to protect them from excessive rains. Other tender plants, like the beautiful *Gerbera Jamesoni*, are also better for slight protection. When severe frost is expected a covering of Spruce or Silver Fir branches laid over them in the manner of roofing tiles will carry off excessive moisture without altogether stopping ventilation. In this locality dampness is our greatest enemy. Preparations for planting the stocks of alpine plants—raised from cuttings and seed and now being wintered in cold frames—are carried out as opportunity occurs. The positions chosen for the various plants are marked with labels, and the allotted spaces filled with suitable soil, so that when planting time arrives all will be in readiness to receive the plants. Advantage is taken of dry, frosty weather to wheel out manure and soil wherever required. On wet days plenty of work can always be found under cover, such as making labels, pegs of various sizes, sharpening stakes, etc. Any trees or shrubs requiring stakes should be given timely attention. Examine all old ties, and see that they are not cutting into and injuring the swelling growths. Numbers of valuable trees are annually spoiled by non-attention to this. Up to the time of writing we have had very little snow in this locality, but the weather is very wintry, and any time now we may experience a heavy fall of snow. Much damage to valuable trees and shrubs may be avoided by shaking the snow off the branches. Good, long, light props should always be kept in readiness for this purpose wherever a choice collection is grown, and care be taken not to injure the young growths.

Lilford Hall Gardens, Oundle, Northants.

SOUTHERN COUNTIES.

Shrubs for forcing.—These are fairly numerous, the chief being Lilacs, Guelder Roses, *Azalea mollis*, Ghent *Azaleas*, *Deutzia gracilis*, *Andromeda floribunda*, *Rhododendrons* of the early-flowering types, *Staphylea colchica*, *Prunus sinensis* fr.-pl., and *Wistarias*. Some of these have to be purchased, while others which can be grown at home have only to be lifted and potted. Where from any cause this matter has not yet had attention, no further delay should be allowed, and the sooner the plants are acquired or lifted, as the case may be, and potted, the more satisfactory the after results. It does not follow that forcing should be commenced at once, unless necessary to do so, but if they are got into the pots and placed outdoors in full exposure they will respond all the more readily when placed in suitable temperatures. Lilacs, *Deutzias*, Ghent and *mollis* *Azaleas* require more warmth to force them into bloom than the other subjects named. With regard to these, a mild, genial warmth suffices to produce the desired effect. As a protection against frost the pots should be surrounded with short litter, well covering the surface of the soil at the same time, or they may be plunged in ashes with a covering of litter on

top to prevent the balls becoming frozen. The heads of the plants should be left quite exposed. So treated, the stock can be drawn upon as required.

Solomon's Seal.—This is quite easily forced, and in lieu of a forcing-house can be brought gently along in a Mushroom-house. When growth is partly developed the plants should be moved out into a warm greenhouse and shaded for a few days or until the growth becomes inured to the light. Only the best of the crowns or rhizomes should be used. The smaller-sized ones can be placed on one side for replanting.

Genista racemosa.—Well-grown plants of this useful subject are always held when in flower in high esteem, and their bright yellow flowers also serve to render the conservatory and greenhouse attractive during the early months of the year. A warm greenhouse temperature usually suffices to bring them into bloom, half-a-dozen plants being a sufficient number to introduce at a time into warmth.

Callas.—Those now pushing up their spathes require a stimulant, nothing being better, when it can be had, than liquid-manure. This, if given in mild doses, can be applied each time water is required, of which a plentiful supply in a tepid state is needed now the plants are in full growth. A sharp look out for fly must be kept and the house vaporised at once should any insects be found present. The latest batch of plants intended for flowering at Easter must be kept quite cool.

Espalier fruit-trees.—These, which usually consist of Apples and Pears, and in less degree Plums and Cherries, should now be pruned so that the borders in which they are grown may, when filled with bulbs—Lily of the Valley, and so forth—not be trampled upon as the new growth begins to push through the soil, as will shortly be the case. This is a very economical way of growing fruit-trees where the garden is of limited extent, and when established they bear heavy crops of fine fruit. The trees may be trained to good stout stakes driven 3 feet apart, but the best and most durable method is to have a post and wire trellis. If the wires are well painted no harm to the branches will ensue. The trees should stand from 12 feet to 15 feet apart, the latter distance being advisable for strong-growing varieties. The actual pruning consists in shortening the spur wood and thinning it out where necessary, as with wall-trained trees, and in confining the spurs to the branches alone. It is a mistake to allow spurs to form on the stems. Young trees should be treated in precisely the same manner as recommended for diagonal-trained trees in a previous note until the full complement of branches has been obtained. If the borders are vacant it is a good plan to give them a good dressing of well-rotted manure after the pruning and the requisite amount of tying are completed.

Cordons.—This is a good method of growing choice Apples and Pears in the open; using a wire trellis for their support, the same as espaliers. The pruning in their case is the same as for wall-trained examples. These also pay for good cultivation. In some instances they are employed to form a covered way in the kitchen garden, the trees being trained to stout wires let into the ground at either end and bent in the form of an arch. Highly-coloured fruits are obtained in this way, and the effect when the trees meet or when the whole of the wires are covered is good.

Rhubarb.—When necessary for any reason to form a new Rhubarb bed in another part of the garden the present is a good time to do so. The new site should be dug at the least two spits deep and plenty of manure incorporated with both layers of soil. When the soil has settled into place the corms may be lifted, divided, and replanted, using the best portions only for this purpose. The rows should stand 4 feet apart, allowing the same distance between the stools. As these should not be pulled from next year, a sufficient number of old stools should be left to keep up the supply in the old bed for another season.

Flower garden.—Where forest trees are numerous on the confines of the grounds, the latter, except where labour is plentiful, get to look untidy from the time the leaves begin

to fall until all are down. A general clean-up has then to take place, which, if thoroughly done, will render the grounds clean and tidy for some time to come. When leaves are very abundant or there are more than are required for hotbed making, the filling of beds in Cucumber and forcing houses, and the forming of a good heap to rot down for supplying leaf-mould for potting and other purposes, they may be employed when manure is scarce for digging in when the soil is heavy or of a clayey nature. In this case they may be used on a very liberal scale. A bed of good length and width may also be formed with them in some inconspicuous spot, which later on can be utilised for the growing of a crop of Potatoes for digging in advance of those grown in the kitchen garden. A. W.

MIDLAND COUNTIES.

The fruit crops were generally satisfactory, with the exception of Apples and Apricots, which were by far the worst crops of the season. Plums were slightly below the average. Pears were plentiful and of good quality. Peaches and Nectarines were an exceptionally good crop, and the fruits were of first-rate quality. All bush fruits were above the average, also Raspberries. Strawberries were a very heavy crop, and good both in size and flavour. The following varieties were exceptionally good:—King George V., Royal Sovereign, Fillbasket, Laxton's Leader, Laxton's Maincrop, Givon's Late Prolific, and Laxton's Latest. Fruit-trees in general promise a good show of blossom buds, especially Apples.

Plant-houses.—Perpetual-flowering Carnations: At this time of year there is no flower to equal these for cutting. Among all the newer varieties that are being continually introduced none is better than the forms of Enchantress, the pink, white, and rose-pink. These are most reliable and at the present time are producing blooms of lovely shades. May Day is also very fine at the present time, its colour, deep satin-pink, remaining good under all conditions. The stems are good and the habit perfect. Other good varieties that are now in full bloom are Empire Day (pale salmon-pink), Baroness de Brien (salmon-pink, strong grower), R. F. Felton (rose-pink), Lucy (salmon-pink), Lady Alington (rich rose-salmon), Beacon (orange-scarlet), Mary Allwood (cardinal pink), Triumph (rich bright crimson), Mikado (glistening heliotrope), and White Wonder (the most perfect white variety yet in commerce). For the next six weeks, the most trying time in Carnation culture, manure, if applied at all, must be meted out with great judgment. Nitrogenous manures, especially, should not be used, a flaccid condition of the flower, accompanied by a weak calyx that more often than not splits, being results which follow their use. Another cause of weakness in some varieties is the production of too many growths, which, if left without reduction, either do not flower or only yield small, worthless blooms. Lady Alington, Empire Day, Mikado, Baroness de Brien are varieties which I have found require attention in this direction. These should be examined and thinned two or three times in the period from October to May. Those left in a very short time increase in vigour. An atmospheric temperature of 50 degs. should be maintained when the weather is mild, but rather than resort to too much fire-heat lower the temperature to 45 degs. Ventilate the house freely on all favourable occasions.

French Beans are much appreciated during the winter, and sowings will now be made once a fortnight to keep up a continuous supply. Seven-inch pots are used for the earliest batches, and 9-inch later. The pots must be well drained and rather more than half filled with a compost of three parts fibrous loam and one part spent Mushroom-manure or well-prepared horse-manure, which should be made moderately firm. From seven to nine seeds should be sown in each, reducing the plants to five in each pot when they have germinated. Until germination has taken place the pots can be stood closely together in almost any position near the hot-water pipes, but afterwards a light position near the glass must be afforded them. As soon as they have made the first pair of leaves, fill the pots

to within $\frac{1}{2}$ inch of the rims with the same kind of compost, after it has been placed in the house to get warmed through. Endeavour to keep the temperature of the house at about 55 degs., allowing the maximum to be 60 degs., and the minimum 50 degs., according to the outdoor temperature. Extreme temperatures either way must be guarded against. Too much fire-heat is worse than allowing the temperature to get somewhat low, as the plants become weakened, and red-spider is almost certain to make its appearance. The atmosphere of the house must be kept moist, and the plants thoroughly syringed with tepid water between 9 a.m. and 10 a.m. on fine days. Pieces of old Birch brooms placed round the edges of the pots with a spray or two in the centre form suitable supports. After the plants have flowered and the blooms set, weak manure-water will assist the quick development of good-sized tender pods, and will also prolong the season of bearing. The pods should be picked immediately they are of sufficient size for use. If not all required for present use, they can be kept for several days by placing the ends in a little water, keeping the vessel in the same temperature as that in which the Beans are growing, and changing the water every day.

The past season has been a good one for most vegetables in this locality, though many crops were somewhat late owing to the heavy falls of snow and rain in March and April, which made it impossible to get in the crops at the usual time. Peas, Beans, Cauliflowers, and other Brassicas gave exceptionally good results, whilst Carrots, Beetroot, Turnips, and Celery have seldom been better. I gathered the first dish of Peas on June 20th from plants raised in pots and planted out on a warm border in April. From that date until the middle of September I was able to keep up good supplies daily, and the last dish was gathered on October 10th. Early varieties of Potatoes, though much later than usual, gave good returns. Maincrop and late varieties were a moderate crop and became badly diseased during September and October. Royal Kidney and King Edward (varieties largely grown in this locality) were the least affected. Tomatoes (out-of-doors) failed to ripen, except in very favoured positions. The condition of all the winter vegetables is perfect, and unless very severe weather prevails there should be an abundance of all kinds. The rainfall for the year to December 13th inclusive was 26.84 inches, which fell on 158 days.

F. W. GALLOP.

SCOTLAND.

Zonal Pelargoniums.—These are never more useful than during the winter and spring. At the present season their requirements are few. Let them be kept in a moderately warm atmosphere, free from damp, and but sparingly supplied with water, and results will be satisfactory. I think in the case of Zonals that it is much better to concentrate on a few varieties with flowers of good colour, and grow serviceable batches of each, than to strive after a "collection," an idea which is in no case satisfactory, let the plant be what it may. For winter blooming Paul Crampel is of a good rich colour, Raspail Improved has much to recommend it, while Rada is of a good shade of cerise, and the old Olive Carr (pink with white eye), is valuable for winter blooming. Among whites there is a good choice—I like Eureka. The older varieties seem to possess a more robust character than do those of more recent origin. With the turn of the year and the increasing root-action, more moisture will be required, with occasionally weak doses of stimulants.

Calceolarias.—At this season, no matter how coolly herbaceous Calceolarias are grown, there will always be a few plants which will throw up flower-stems. Such plants may as well be got rid of without delay. If permitted to develop, the blooms are out of season and almost invariably of poor quality; while if the stems are pinched out, the chances are that the plant, if it does not collapse, will never be satisfactory. A close watch ought to be kept for incipient outbreaks of aphid, at all times inclined to infest Calceolarias. Vaporising at intervals will keep this pest at bay. The present-day plantsman has much to

be grateful for in this handy and effectual method of dealing with this and similar insects—the disagreeable fumigations with Tobacco paper, common a quarter of a century ago, being now entirely obsolete.

Early Vines.—The increasing price of fuel, and in some districts the difficulty of obtaining it, will interfere with very early starting of Vines in many instances. It is usual to make a beginning with Black Hamburgh, Foster's Seedling, Buckland Sweetwater, and similar varieties at this time. When the house is closed let the temperature be maintained at as steady a figure as possible. The right temperature at first may be about 50 degs., rising gradually to 55 degs., with the thermometer at 60 degs. when the buds expand. To ensure the buds breaking regularly the Vines may be slung in an almost horizontal position until growth begins, and if they are slow in starting if the position of the rods can be reversed it will be found beneficial. In the case of very sluggish canes, I have noticed good results from the following treatment: Take the point of the rod in the hand and twist it spirally until the pressure extends to the roots. It always seems to me that after this twisting the sap flows much more freely. At any rate, I am quite convinced that such is the case with pot Vines, which respond to this treatment, in the case of sluggards, in quite a remarkable way.

Peach-houses.—If it is intended to replace any of the existing trees, no time should now be permitted to elapse until the renewing takes place. Naturally, the border in the immediate neighbourhood of the new tree or trees must be renewed, and a good allowance of lime or of lime-rubble ought not to be forgotten. It is always a good plan to have coming on out-of-doors, on a south wall, a few young trees, which can be lifted and planted indoors. This permits of a crop being taken during the first season after planting. For early work, Amsden June and Hale's Early are good sorts. These can be followed by Dymond and Royal George. Stirling Castle is a reliable and favourite Peach for indoor work, and although practically colourless Alexandra Noblesse is rather a taking fruit. Among Nectarines, Early Rivers and Cardinal are useful for first crops, Stanwick Elruge, Pineapple, or Humboldt making a good succession. Goldoni may be planted with confidence. Lord Napier has in some places a habit of cracking as ripening time approaches, which makes one chary of recommending it—good Nectarine though it be. Every grower, however, has, as is quite natural, his own favourites.

Hardy fruit.—Those who may be planting Apples at the present time would do well to notice the varieties which succeed in their own immediate neighbourhood. Apples which succeed in one district will fail in another, and disappointment follows. Bismarck is a good bearer, and produces fruit of a useful type, but it is rather capricious in some districts, and has had to be discarded here. Lane's Prince Albert and Frogmore Prolific are free croppers, and keep well. Alfriston, Wellington, and Bramley's Seedling are alike prolific and long-keeping varieties. Those who have to deal with an exposed situation might profitably plant the Galloway Pippin—a good keeper, and while, strictly speaking, a kitchen variety, not to be despised for the dessert. The Apples referred to have been named for their useful cooking qualities. Dessert Apples are a class by themselves, and, in planting, the taste of the consumer must be consulted; Apples which are considered excellent by one not being appreciated by another. One thing is certain. It is almost impossible for a beginner to make a satisfactory selection from a nurseryman's catalogue. There are far too many varieties, the would-be grower becomes confused, and disappointment follows.

Raspberry canes.—The foliage having fallen, the final thinning and training have been accomplished. I yet adhere to the old practice of "bowering" the canes. For those who are not acquainted with this method it may be briefly described. The canes are planted in clumps—from five to seven canes being allowed to each clump—at intervals of 5 feet. Midway between each clump a stout post, 4½ feet high, is driven in, and the canes on either side are "bowered" over and secured to the post by means of tarred twine. As the crops of fruit

obtained from canes so treated are annually very heavy, I have never considered it needful to change the system. One thing is very certain: A large plantation can be very quickly got over—much more quickly than is the case when individual canes are closely planted and secured separately to wire supports—a fact not to be lost sight of at present. No matter how good a given variety may be, close observation will show that certain canes are much superior to others, alike in respect of productiveness and of robustness. If such canes be marked, and suckers propagated from them, it becomes possible to build up an improved type of the variety in the course of a few years. By rigid selection and regular propagation there has been built up in these gardens a much superior type of Superlative, the fruit of which in point of size almost equals that of the Loganberry, and the canes of which are massive and prolific. Superlative, Baumforth's Seedling, and Füllbasket can be confidently recommended to intending planters.

Wall trees.—Recent frosts having now, in the case of all trees except Peaches and Nectarines, cleared off the foliage, a beginning has at length been made with the pruning and nailing. As the wall trees are well dealt with at the time of the summer pruning, the work now is reduced to a minimum. In the case of trees which have filled their allotted space, the shortening or clearing out of spurs, as is necessary, together with the regulation or renewal of the ties is all that is required. So far, and until the work was interrupted by rain, considerable progress has been made with Apples and Pears; and it is hoped to continue, and, if possible, finish the wall trees during the ensuing week.

Plant-houses.—Chrysanthemums last well, the mid-season varieties now taking the place of the earlier types and of the singles—the latter of which, with a few exceptions, are now past their best. W. McGURIOG.

Balmæ Gardens, Kirkcudbright.

LAW AND CUSTOM.

COMPENSATION FOR MARKET GARDENERS.

A good many market gardeners are still in doubt as to what precisely are their rights of compensation on quitting their holdings, and it may be useful to set out here the true legal position of the market gardener as it was after the passing of the Agricultural Holdings Act, 1908, which was what is known as a Consolidating Act, and in which there was embodied a good deal of the existing law touching the right of market gardeners to compensation.

The position of the market gardener can therefore be best explained by giving a short epitome of the provisions of Section 42 of the Act of 1908. That section requires first of all that there shall be a written agreement between landlord and tenant that the holding is to be let or treated as a market garden. Then the fact of such written agreement being in existence automatically adds certain things to the list of improvements an ordinary farming tenant may carry out without consulting his landlord and receive compensation for. These "extras," in respect of which market gardeners (and they only) can claim are:—(1) planting of standard or other fruit-trees permanently set out; (2) planting of fruit bushes permanently set out; (3) planting of Strawberries; (4) planting of Asparagus, Rhubarb, and other vegetable crops which continue productive for two or more years; (5) erection or enlargement of buildings for the purposes of the trade or business of a market gardener; provided, too, that the right of an incoming tenant to claim compensation in respect of the whole or part of an improvement which he has purchased may be exercised, although his landlord has not consented in writing to such purchase.

With regard to new buildings and fixtures which have been added by the tenant we must look first of all at what the Act provides in regard to ordinary farmers, because the market gardener is entitled to the full benefits in the first place that any farmer can secure. The Act not only provides that compensation shall be paid to a farmer for the erection, enlargement, or alteration of buildings to which the consent of the landlord has been given, but it also provides for compensation being paid in respect of repairs to buildings, being buildings necessary for the proper cultivation or working of the holding, other than repairs which the tenant himself is under an obligation to execute: provided that the tenant before beginning to execute such repairs shall give to the landlord notice of his intention in writing together with particulars of such repairs, and shall not execute the repairs unless the landlord fails to execute them within a reasonable time after receiving such notice. The market gardener has the value of these provisions together with an additional benefit for himself provided in the third schedule, which requires the landlord, among other things, to pay compensation to a tenant who has erected or enlarged buildings for the purpose of his trade or business as a market gardener. As regards fixtures and buildings added by the tenant, the Act provides that its benefits are to be extended to every fixture and building added by the tenant to the holding, or acquired by him since December 31st, 1900, for the purpose of his business as a market gardener.

A few words now as to the right of the market-gardening tenant to remove any portion of what he has planted. Some tenants naturally want to be able to remove as much as possible to a new holding. With regard to that it is lawful for the tenant of a market garden to remove all fruit trees and fruit bushes planted by him on the holding and not permanently set out; but if the tenant does not remove such fruit trees and fruit bushes before the determination of his tenancy they will remain the property of the landlord, and the tenant will not be entitled to any compensation in respect of them.

This article would not be complete without some reference to the general compensation which a market gardener, in common with every other agriculturist, is entitled to in respect of improvements set out in the third schedule to the Act—e.g., manuring, compensation for feeding-stuffs used, laying down of Grass and other seeds, and repairs to buildings. The position of the market gardener here is quite a favourable one. Where, under a contract of tenancy in existence on January 1st, 1896, a holding was in use or cultivation as a market garden with the knowledge of the landlord, and the tenant has executed thereon, without the consent of the landlord, any improvement covered in this third schedule, the provisions of this Section 42, which we are now discussing, are to apply as if it had been agreed in writing after January 1st, 1896, that the holding should be let as a market garden, so, however, that these improvements in respect of which compensation is to be given are to include such as have been executed before, as well as after, that date; and there is the further important proviso that where the market-gardening tenant holds his land on annual tenancy, and not upon a tenancy under a lease, the compensation payable in any event shall be such as an annual tenant might have claimed if this Act had never been passed.

CORRESPONDENCE.

Questions.—*Queries and answers are inserted in GARDENING free of charge if correspondents follow these rules: All communications should be clearly written on one side of the paper only, and addressed to the EDITOR of GARDENING, 63, Lincoln's Inn Fields, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent each should be on a separate piece of paper, the name and address being added to each. As GARDENING has to be sent to press some days in advance of date, queries cannot always be replied to in the issue immediately following their receipt. We do not reply to queries by post.*

Naming plants.—*All who wish their plants to be rightly named should send fair examples of each—the stem, leaf, flower, or fruit. (Snippets of leaves and points of shoots are useless.) Not more than four plants should be sent in any one week by the same correspondent. Where more than one kind is sent they should be numbered. Of conifers the fruit should always be sent.*

Naming fruit.—*Several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruits for naming, these in many cases being unripe and otherwise poor. We can undertake to name only four varieties at a time.*

PLANTS AND FLOWERS.

Mice and Tulip bulbs (C. F.)—The only way is to trap and poison them. The latter is the more summary method, but the former is the safer. It is wise to occasionally vary the kind of trap and the bait. We have always managed to keep down mice by using the figure 4 brick trap, baiting with cheese, fat meat, or the seed of garden Beans softened by soaking for a time in water.

Oleander unhealthy (F. T.)—The Oleander leaves were swarming with mealy-bug, brown-scale, and red-spider. The black, sticky slime is caused by the brown-scale and mealy-bug. Set to work and sponge the leaves at once frequently with strong Tobacco-water, in which some soft-soap has been mixed, using the same remedy for any other hard-leaved plant in the same house similarly affected. Continued perseverance in the sponging is necessary.

Sediment on leaves of greenhouse plants (P.)—We think, if you will examine the Orange-tree, you will find that it has been attacked by brown scale, which is evidently spreading to the other plants in the house. The plants have also been attacked by green-fly, which has caused the sediment on the leaves. The best cure for green-fly is fumigating with one of the many remedies advertised in our pages. You must wash the Orange leaves carefully with some insecticide.

Repotting Camellia (G. M.)—The beginning of March will be a good time to repot the Camellia in a mixture of good turfy-loam and peat, with some sharp silver-sand added; the pot should be well drained. After the plant is potted it should be placed in a comfortably warm house, and should be encouraged to freely by the aid of frequent syringings. Water should be given on all bright days. Mossy growth that appears on the surface of the soil should be immediately removed.

Chinese Primulas failing (S.)—Your Primulas appear to have been in a too low temperature. To get good leaves and blooms more food may be required, and more warmth, at the same time giving plenty of air. Keep up a higher temperature; give more food, with plenty of air on back or top of house in fine weather. The atmosphere being charged with moisture now, a little warmer temperature with air is required.

Camellia buds dropping (M. J.)—The most probable reason of the Camellia losing its flower-buds is that it has been allowed to get dry at the roots. If you give water in dribbles, that is almost sure to be the reason. Examine the state of the soil in which it is growing, and, if found to be dry a little way beneath the surface, set the plant in a tub of water, where let it remain until you find that the bubbles have ceased.

Ferns doing badly (R.)—You had better get the plants out of the china pots at once, and as best you can. In these there are, as a rule, no holes for drainage, while the glazed sides are unfavourable to the healthy action of the roots, so that the soil becomes sour after a time, and then the plants fail. They should be carefully repotted in ordinary pots, just large enough to hold the roots, using some nice, sweet, fresh peaty ordinary soil, with plenty of sand, and be placed in a warm greenhouse or stove with a moist atmosphere, where they will probably soon commence making healthy growth again.

Begonia discolor Rex in winter (E. B.)—Begonias of the discolor Rex class are not deciduous, neither do the plants form tubers, hence they must be kept watered during the winter. Of course, at that season they will not require so much as when the days are bright and they are growing freely, but the soil must be kept fairly moist. They do not require any absolutely resting period. A winter temperature of 60 degs. to 65 degs. suits them well. They can be readily propagated by cuttings in the spring, as the members of the discolor Rex section do not grow from leaves so readily as the different varieties of Begonia Rex itself.

Solanum capsicastrum (C. P.)—Cut the branches back in March to about half their length, and place in the greenhouse; then, when the young shoots commence to start, repot in a compost of two-thirds loam and one-third leaf-soil, with a little sand. The pot will have to be a size larger, and in repotting remove a little of the old soil. Keep the plant indoors till the end of May, and then stand in a sunny spot out-of-doors to induce it to flower and produce berries. When frosts threaten in the autumn, again remove to the greenhouse or a sunny window. Take care it has plenty of water during the summer months while standing in the open air. It is easily increased from cuttings and seeds in the spring.

VEGETABLES.

Seakale (J. W.)—Open a trench on one side of your Seakale bed, and get out carefully every root, preserving every portion. Hard trim all the strong main roots of all side roots, and lay all these trimmings together in one way. The main roots having strong crowns may be 8 inches long. These should be laid into soil, chopping down a furrow for the purpose deep enough with a spade, and placing the roots in thickly, crown upwards, putting soil against them. So placed you can get in a score or so at a time into any quite dark place, three parts burying in soil and watering. If there be warmth, growth soon follows, and when 7 inches high the crowns may be cut and cooked. Trim all the pieces of side roots

to lengths of 5 inches, making the bottom end slanting, the top cuts quite level. Dibble these out into rows 20 inches apart, and 12 inches apart in the rows, in the coming spring in soil trenched and well manured, and you will have a fine lot of plants to lift and force next year. Do the same every year.

MISCELLANEOUS.

Worms in pots (S.)—We think the best way of dealing with the worms in the pots is to get some fresh lime and make a solution of lime-water—say, a quart of lime to a gallon of water. Stir it well and let it stand for a few hours until the water is quite clear, then pour off into a water-pot and give to the pots in which the worms are. This should be repeated two or three times in the case of plants with a large ball of earth attached to the roots, as it may not be possible to kill all the worms at one watering. Many of the worms may be taken out when the plants are repotted, but perhaps not all; therefore, it is well to apply the lime-water first.

Basic slag for lawns (Gardener)—Basic slag is a very finely-crushed powder, made of the slag that is given off in the process of converting iron into steel by means of what is known as Thomas's patent. Hence it is also known as Thomas's phosphate powder. It has, of course, in it some slight metallic character, but as it is chiefly of chemical composition it is found to contain a good proportion of phosphates. It is a slow-acting manure, probably one of the slowest, and it should be used at once, so that it may to some extent become soluble under the influence of the winter rains. You should apply the manure at the rate of about 5 lb. per rod. We fear its application will not permanently remedy the sourness or wetness of your lawn. Bad drainage is probably the cause of the sourness of the soil, in which case top-dressing will be of no avail until you have thoroughly drained it.

Leather-jackets (N. S. T.)—The grub you send specimen of is that of the Daddy-long-legs (*Tipula olearacea*). These grubs are generally known by the name of "Leather-jackets," on account of the toughness of their skins. They are very troublesome because of the difficulty of destroying them. The toughness of their skins and their subterranean habits render it almost impossible to kill them with any insecticides. They do not like drought, but wet and cold have no effect on them. Hoeing the ground is useful, as it exposes them to the birds. Rooks and starlings are especially fond of them. Laying pieces of board, turf, slate, bricks, or tiles near the plants they are attacking make good traps for them. They often ramble about at night and find such things convenient to hide under during the day. The traps should be examined every morning and replaced in the position they formerly occupied. Dressing the ground with one of the many soil fumigants now to be had should do good.

NAMES OF PLANTS AND FRUITS.

Name of plant.—*Wm. Sheringham.*—Flowers very much dried up, but, so far as we can make out, the specimen is *Browallia elata*.

THE ENGLISH FLOWER GARDEN AND HOME GROUNDS.

Design and arrangement shown by existing examples of gardens in Great Britain and Ireland, followed by a description of the Plants, Shrubs, and Trees for the Open-air Garden and their Cultivation.

By W. ROBINSON, Author of "The Wild Garden," etc.

ILLUSTRATED WITH ABOUT EIGHT HUNDRED WOOD ENGRAVINGS.

PART I.

Art in the Garden. Design and Plans in Relation to the House and Home Landscape. Various kinds of Flower Gardens with a view to Artistic Effect and Good Cultivation. Artistic Use of the Great Groups of Plants for the Open-Air Gardens in the British Isles. Alpine, Rock, and Border Plants, Climbers, Annuals and Biennials, Flowering Trees, Shrubs and Evergreens; Water and Bog Plants, Hardy Ferns, Fine-leaved, Bedding, and Half-hardy Plants, Roses, Spring, Summer, Autumn and Winter Gardens, Hardy Bulbs; Orchard Beautiful. The Wild Garden, Flowers for Cutting, Colour and Fragrance. Labours for Good or Evil. Lawns and Pleasure Grounds. Illustrated from Existing Examples of British Gardens Engraved on Wood.

PART II.

Containing the Flowers, Flowering Shrubs and Trees, Evergreens, and Hardy Ferns for the Open-Air Flower Garden in the British Isles, with their Cultivation and the Positions Most Suitable for them in Gardens.

Followed by a comprehensive Index of 18 pages.

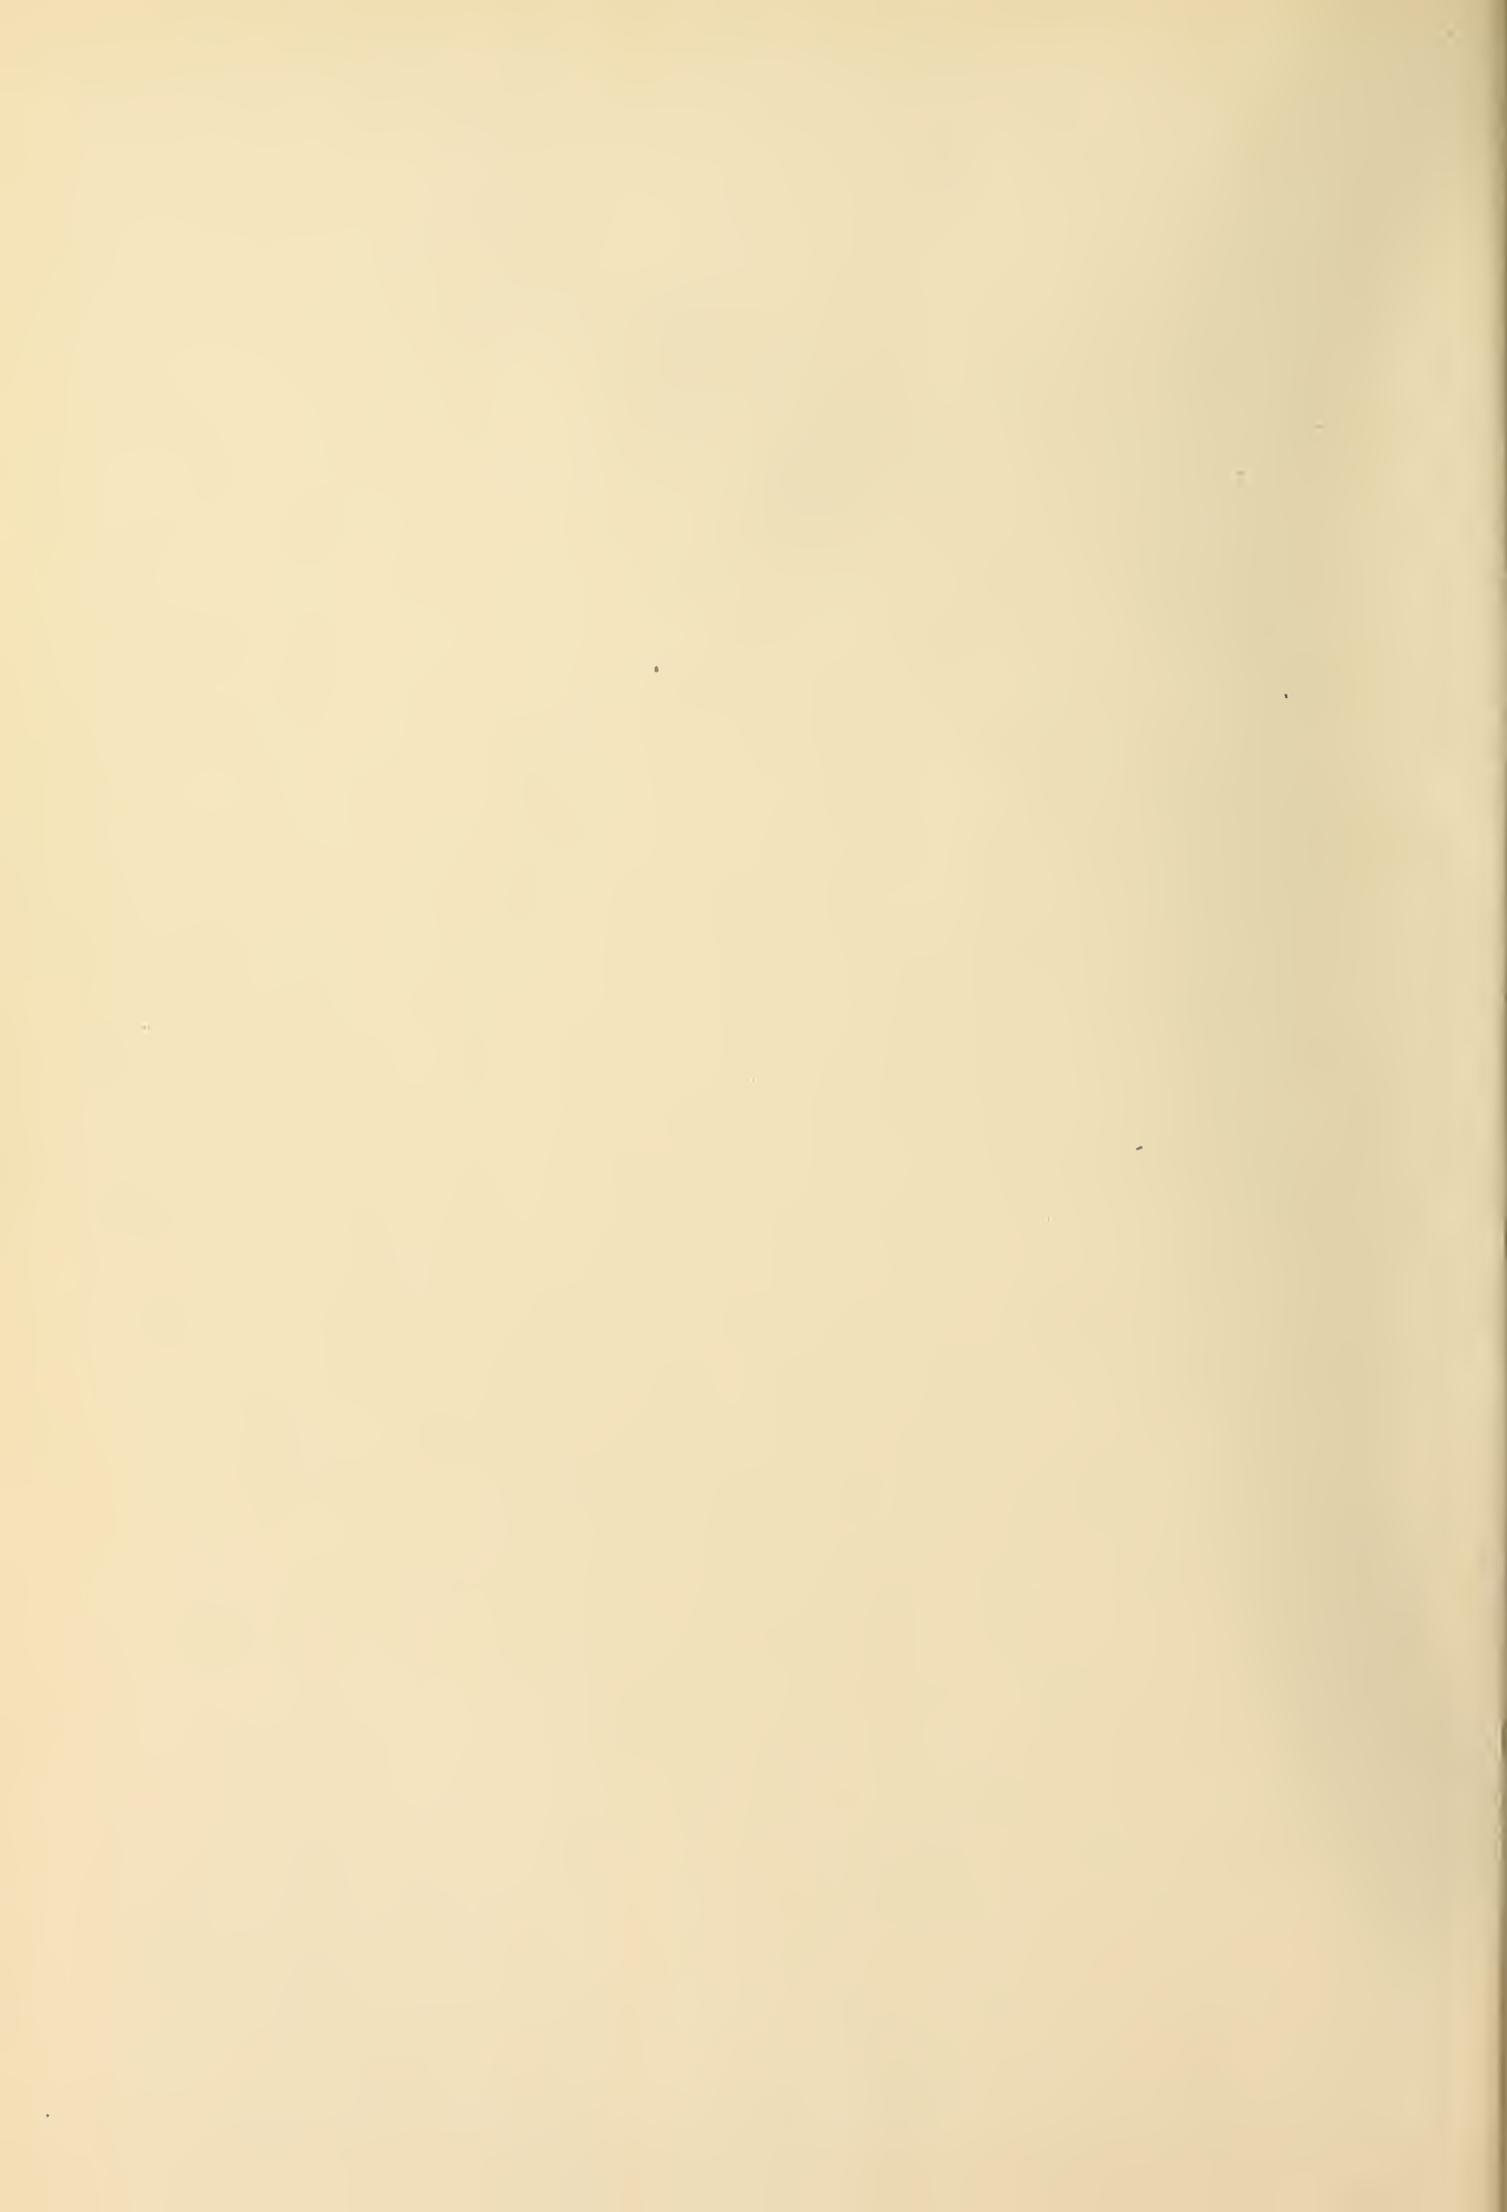

"A garden is a beautiful book, writ by the finger of God: every flower and every leaf is a letter. You have only to learn them—and he is a poor dunce that cannot, if he will, do that—to learn them and join them, and then to go on reading and reading. And you will find yourself carried away from the earth by the beautiful story you are going through. . . . And then there are some flowers that seem to me like over-dutiful children; tend them but ever so little, and they come up and flourish, and show, as I may say, their bright and happy faces to you."—DOUGLAS JERROLD.

POPULAR EDITION, one volume, 15/-; post free, 15/6.

SUPERIOR EDITION, one volume, finely and strongly bound sage green, half morocco, 21/-; post free, 21/6.

TWO-VOLUME EDITION, half-bound vellum, for Library or Presentation purposes, 24/- complete; post free, 24/6.

London: JOHN MURRAY, and of all Booksellers; or from this Office, 63, Lincoln's Inn Fields, London, W.C.
